The perennial subject of student technical papers, particularly with reference to District and national prize competition and rules governing such competitions, came up for extended discussion. The general consensus of opinion seemed to be that the question of a proper basis for national grading of student papers "is not yet satisfactorily settled."

Student Branch counselors came in for self-discussion, in connection with successful and effective conduct of Branch activities. Emphasized during the discussion was the fact that the Branch counselorship is "an important position involving certain definite responsibilities as well as certain privileges," and that the office should not be held by any one man for any great length of time, but should be passed around among available faculty members so that full benefit might be derived from "new blood."

**Director F. Ellis Johnson, of the University of Missouri, Columbia, chairman of Student Branches committee presiding**

Student leadership, and the training of students for leadership, was believed by many to be one of the most important functions and opportunities of the Student Branch. It was strongly opined that the Branch "should be operated as a training ground for leadership," and that consequently as many students as possible should have the opportunity of serving as Branch officers and otherwise actively participating in the development and conduct of Branch affairs.

**Group at head table at conference of Student Branch counselors, left to right: Past Vice-President W. H. Timbie, Massachusetts Institute of Technology, Cambridge; Past-President Chas. F. Scott, Yale University, New Haven, Conn.; Director F. Ellis Johnson (chairman) University of Missouri, Columbia; W. E. Wickenden, Case School of Applied Science, Cleveland, Ohio; Past Vice-President H. V. Carpenter, State College of Washington, Pullman; T. F. Ball, University of South Carolina, Columbia; A. B. Newman (member of American Institute of Chemical Engineers) Cooper Union, New York, N. Y. In the foreground is W. R. Work, Carnegie Institute of Technology, Pittsburgh, Pa.**

## Executive Committee of Southern District Meets

A meeting of the executive committee of the Institute's Southern District (Number 4) was held at Chattanooga, Tenn., December 5, 1936. The following attended:

W. W. Hill, counselor, Alabama Polytechnic Institute Branch
K. L. Dillon, secretary, Alabama Section
C. W. McCracken, Birmingham, Ala.
J. M. Flanigen, secretary, Atlanta Section
Stanley Warth, chairman, Louisville Section
W. A. Smith, chairman, Florida Section
E. A. Corum, chairman (now past-chairman), Memphis Section
J. E. Jackson, chairman, Virginia Section
A. P. Farrow, secretary, East Tennessee Section
Chase Hutchinson, chairman, East Tennessee Section
E. E. George, vice-chairman, East Tennessee Section
F. E. Johnson, secretary, New Orleans Section
W. J. Seeley, student counselor, Duke University Branch
Mark Eldredge, vice-president, Southern District
R. F. Crenshaw, secretary, Southern District

The District co-ordinating committee to function according to section 33 of the AIEE by-laws was selected as follows: Mark Eldredge and R. F. Crenshaw, *ex-officio;* F. W. Russell, Louisville, Ky.; H. N. Pye, Atlanta, Ga.; W. W. Hill, Auburn, Ala.; C. W. Ricker, New Orleans, La.; and K. L. Dillon, Birmingham, Ala.

Activities of the Sections were discussed by Vice-President Eldredge, following which the delegates representing the various Sections in the District gave brief outlines of the activities of their respective Sections. Mr. Hill summarized the student Branch activities, and mentioned that a District student conference is to be held in April at Auburn, Ala., with representatives from other colleges attending.

Members of the committee next partook of a delightful luncheon, arranged by Mr. George, as guests of the Tennessee Electric Power Company. Following the luncheon, Edwin D. Wood, director and general superintendent of the Louisville (Ky.) Gas and Electric Company, was unanimously nominated as the District candidate for vice-president to succeed Mr. Eldredge. E. E. George was chosen to represent the District on the national nominating committee.

The monthly publication of the Institute, ELECTRICAL ENGINEERING, was the next topic for discussion. After considerable discussion of various phases of the publication, it was unanimously voted that the committee send the following resolution to headquarters:

That in order to increase interest and value to the students and memberships at large, the journal should include a summary of each article being approximately 10 per cent of the length of the article and written by the technical staff of the journal, which would outline the paper or article for most readers without including the subject matter in a theoretical nature. Also that more illustrations and practical applications be presented whenever possible.

Vice-President Eldredge gave a brief account of the discussion at a recent meeting of the Institute's board of directors on the branching out of electrical engineers into fields beyond electrical engineering, such as economics, to encourage electrical engineers to study and be actively engaged in other subjects of world interest. It was suggested that every effort be made to stimulate employers to consider an applicant's activity in engineering organizations

when evaluating his qualifications in addition to education and practical experience. The importance of engineers in executive positions in actively engaging in the affairs of engineering organizations was emphasized.

Following discussion of other routine matters, the committee was taken on an inspection tour through the dispatching headquarters of the Tennessee Electric Power Company.

## Acoustical Terminology Standard Completed by ASA

A standard acoustical terminology for engineers which is intended to eliminate confusion in motion picture, radio, and building fields has just been completed, according to an announcement by the American Standards Association. This standard is the work of engineers, musicians, manufacturers, and scientists, and has been 4 years in development. According to Leopold Stokowski, a member of the committee in charge: "In the America of the future radio and motion pictures will be important in developing our civilization. For this we need a complete understanding between engineers and musicians." The new standard is expected to achieve this "understanding."

The committee gives a broader meaning to the word "noise," now defined in terms of the listener as an "unwanted" sound rather than in terms of the sound itself. A section of the standard deals with architectural acoustics. Another section that provides standard terms for the measurement of hearing will be useful to the medical profession and to manufacturers of aids for the partially deaf. Other parts dealing with the conversion of sound to electrical energy and with acoustic transmission systems will be of particular value in motion picture and radio work.

A separate section for music brings engineers and acoustical experts into agreement with musicians on a basic standard pitch, the importance of which can be judged by the fact that an increase of only 4.14 per cent in pitch carried out through the entire keyboard of a piano would throw an additional strain of approximately half a ton on the framework of the instrument.

Standards for reference and intensity levels for sound measurement and for characteristics of measuring instruments have already been completed.

## Lamme Medal Awarded to Frank Conrad

The 1936 Lamme Medal of the AIEE has been awarded to Doctor Frank Conrad (A'02) assistant chief engineer of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., "for his pioneering and basic developments in the fields of electric metering and protective systems." The medal and certificate will be presented to him at the annual summer convention of the Institute, to be held in Milwaukee, Wis., June 21–25, 1937. A biographical sketch of Doctor Conrad may be found in the "personals" columns of this issue.

The Lamme Medal was founded as the result of a bequest of Benjamin G. Lamme, chief engineer of the Westinghouse Electric & Manufacturing Company, who died on July 8, 1934; this bequest provides for the award by the Institute of a gold medal (together with a bronze replica thereof) and a certificate annually to a member of the AIEE "who has shown meritorious achievement in the development of electrical apparatus or machinery," and for the award of 2 such medals in some years if the accumulation from the funds warrants. A committee composed of 9 members of the Institute awards the medal. Previous recipients of the award have been: 1928, A. B. Field (A'03, F'13); 1929, R. E. Hellmund (A'05, F'13); 1930, W. J. Foster (A'07, F'16); 1931, Guiseppe Faccioli (A'04, F'12, deceased); 1932, Edward Weston (A'84, M'84, past-president, deceased); 1933, L. B. Stillwell (A'93, M'92, F'12, member for life, past-president); 1934, H. E. Warren (A'02), and 1935, Vannevar Bush (A'15, F'24).

Mr. Lamme made similar bequests to the Society for the Promotion of Engineering Education and Ohio State University, providing in the former for the annual award of a medal "for accomplishment in technical teaching or actual advancement of the art of technical training," and in the latter for the annual award of a medal to a graduate of Ohio State University in any branch of engineering for meritorious achievement in engineering or the technical arts. The 3 organizations adopted a common obverse for their medals, and each prepared a suitable reverse.

## Special Committee on Dues Recommends No Change

FOR several years a special committee of the AIEE has studied the matter of dues and membership grades with particular reference to the dues of Associates.

A final report was presented to the AIEE board of directors on January 26, 1937, recommending that no changes be made in dues or in membership grades at this time. The report was acted upon favorably by the board at this meeting.

An intensive study over a long period forced the committee to come to this conclusion. Any endeavor to place a time period in any membership grade with a change of dues involved the same fundamental criticisms that have been applied to the present rules. Any endeavor to make one fee for each grade without a time period involves increasing the dues in other grades or a penalty on the admission of young engineers.

An endeavor to get uniformity in grades and dues for the founder societies was made without success and a study of the accompanying tables shows that dues and grades for the AIEE are in line with the practices of these societies.

A statistical study of dues and members and of the effect of the increase in dues for 6-year Associates gives no evidence that this increased fee acts to deprive the Institute of members.

The membership on May 1, 1936 (including those who were in arrears for only one year on that date) developed dues charges to a total of $192,085, and the grade classifications were as follows:

| | |
|---|---|
| 691 Fellows @ $20 | $ 13,820 |
| 3,829 Members @ $15 | 57,435 |
| 5,258 6-year Associates @ $15 | 78,870 |
| 4,196 less-than-6-year Associates @ $10 | 41,960 |
| Total | $192,085 |

To revert to the former practice of charging all Associates $10 dues would have reduced the above total to $165,795, a difference of $26,290.

The membership committee of the New York Section recently made a recommendation that the dues of all Associates, without regard to length of membership, be fixed at $12.50. If this provision had been in effect on May 1, 1936, the total dues charges would have been $189,430 or $2,655 less

**Table I—Entrance Fee and Dues of Engineering Societies**

| Grades | ASME | | ASCE | | AIME | | AIEE | |
|---|---|---|---|---|---|---|---|---|
| | Entrance Fee | Dues | Entrance Fee | Dues | Entrance Fee | Dues | Entrance Fee | Dues |
| Fellow | $30 | $25 | $ | $ (b) | $ | $ | $20 | $20 |
| Member | 25 | 20 | 30 | 20 | 20 | 15 | 15 | 15 |
| Associate member | | | 25 | 20 | | | | |
| Associate | 25 | 20 | | | 20 | 15 | 10 | (f) 10 |
| Affiliate | | | 30 | 20 | | | | |
| Junior member | 10 | (a) 10 | 10 | (c) 10 | | | (e) 10 | |
| Junior foreign affiliate | | | | | | | 5 | |
| Student members | | 3 | | (d) | | | 2 | 3 |

(a) Dues of junior member grade increased to $20 after 6 years of membership.
(b) All members located within district number 1 (i.e., territory within 50 miles of New York City) pay $5 more than the amount indicated for each grade.
(c) Membership ceases at 33 years of age, unless previously transferred to grade of associate member.
(d) Membership in a student chapter includes privileges of special subscription rates to society publications.
(e) Dues charge of $10 obtains only for first 6 years after election or until reaching age of 33; thereafter charge is $15.
(f) Increased to $15 after completion of membership term of 6 years.

**Table II—Associates Resigned and Dropped From May 1, 1927 to May 1, 1930**

| | 6-Year Associates | | Associates | |
|---|---|---|---|---|
| | Number | Per Cent | Number | Per Cent |
| May 1, 1927: | 6,101 | | 8,664 | |
| Dropped | 425 | 7.0 | 739 | 8.5 |
| Resigned | 205 | 3.3 | 234 | 2.7 |
| Total | 630 | 10.3 | 973 | 11.2 |
| May 1, 1928: | 6,037 | | 8,401 | |
| Dropped | 395 | 6.5 | 707 | 8.4 |
| Resigned | 156 | 2.6 | 173 | 2.1 |
| Total | 551 | 9.1 | 880 | 10.5 |
| May 1, 1929: | 6,303 | | 7,756 | |
| Dropped | 295 | 4.7 | 566 | 7.3 |
| Resigned | 197 | 3.1 | 167 | 2.1 |
| Total | 492 | 7.8 | 733 | 9.4 |
| May 1, 1930 | 6,664 | | 7,069 | |

**Table III—Associates Resigned and Dropped From May 1, 1933 to May 1, 1936**

| | 6-Year Associates | | Associates | |
|---|---|---|---|---|
| | Number | Per Cent | Number | Per Cent |
| May 1, 1933: | 6,671 | | 5,747 | |
| Dropped | 861 | 12.9 | 801 | 13.9 |
| Resigned | 315 | 4.7 | 188 | 3.3 |
| Total | 1,176 | 17.6 | 989 | 17.2 |
| May 1, 1934: | 6,140 | | 4,659 | |
| Dropped | 731 | 11.9 | 775 | 16.6 |
| Resigned | 174 | 2.8 | 88 | 1.9 |
| Total | 905 | 14.7 | 863 | 18.5 |
| May 1, 1935: | 5,632 | | 4,225 | |
| Dropped | 326 | 5.8 | 379 | 9.0 |
| Resigned | 137 | 2.4 | 107 | 2.5 |
| Total | 463 | 8.2 | 486 | 11.5 |
| May 1, 1936 | 5,679 | | 4,299 | |

than the total actually charged in our records. It seems to the committee that the establishment of dues of all Associates at $12.50 would materially reduce the number of recent graduates applying for admission.

In table I data are shown regarding the dues, and special arrangements applicable to them, of the 4 large national engineering societies. In this tabulation it may be noted that the dues of the American Institute of Mining and Metallurgical Engineers do not differ greatly from those of the AIEE, and that the dues of the American Society of Civil Engineers and The American Society of Mechanical Engineers are materially higher. It is also significant to note that both the AIME and ASME have adopted provisions similar to that of the AIEE, adjusting the dues charge to the junior member grade after 6 years or after the age of 33 in the AIME. The ASME no longer terminates membership in the junior grade at the age of 35 as was the practice until a few years ago. It seems obvious that on the basis of any comparison with the dues of the other societies the Institute's arrangements appear favorable.

In tables II and III is information regarding the numbers of Associates who resigned and who were dropped during 3 fiscal years beginning May 1, 1927, and in 3 fiscal years beginning May 1, 1933, in order that the results both during and before the depression may be noted.

The percentages of Associates of less than 6 years standing who were dropped are higher in all 6 years than those of Associates of more than 6 years standing. The percentages of Associates of more than 6 years standing who resigned were higher in 5 of the years than the percentages of those of less than 6 years, but, of course, the figures for resignations are far below those of the numbers dropped. Hence, the total percentages dropped and resigned are higher for the less-than-6-year Associates in 5 of these 6 years.

Table IV is included to give some very recent figures regarding Associates who were delinquent. These do not indicate any adverse effects of the change in dues.

The committee has had opportunities to study during the past few years a great many tables dealing with these matters. The tables presented herein seem to be representative. After watching with the greatest care the results of the change in dues of Associates since the adoption, the committee concludes that the increase has had no appreciable effect upon the losses from the membership.

It seems essential to offer some reduction in dues to recent graduates for a few years. Since they constitute a high percentage of Associates admitted, it seems unnecessary and undesirable to make provisions for different dues for 2 groups, one including the recent graduates and the other including any other Associates admitted.

Some members have said that on account of the psychological effects of the present arrangements some kind of a change should be made. Any other plan involving a change in dues after the lapse of a certain period of time would, in the opinion of the committee, cause fully as much dissatisfaction as does the present plan. The types of members who will be a credit to the Institute seldom object, and we should not be unduly influenced by the "kicker" class. The committee has not heard any good reason why Associates should not after 6 years pay their fair share of the cost of conducting Institute activities.

A printed sheet has for 5 or 6 years been sent to all Associates at the time they reach the end of the 6-year period and are called upon to pay the dues of $15. Since headquarters has been supplying this information directly to the individuals concerned there have been fewer complaints than before.

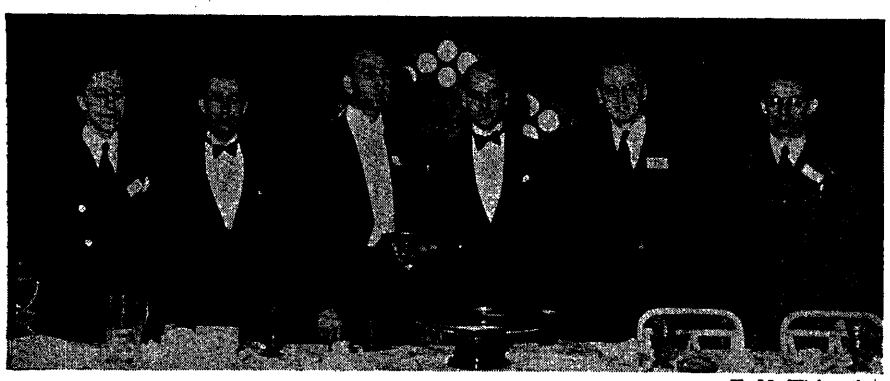
It seems to the committee that there are obvious advantages in the flexibility of the provisions for Associates who are in the 3 large groups mentioned in paragraph 6 of the printed information.

In view of the thorough study made of the effects of the present system and of all possible suggestions for changes, the committee agreed to the conclusion that no changes be made at this time.

The special committee to consider dues of associates and related matters was appointed in 1932; the following served on the committee: L. W. W. Morrow (chairman 1935–37), H. H. Barnes, Jr. (chairman 1932–33), H. Goodwin, Jr., W. H. Harrison, J. Allen Johnson (deceased, chairman 1933–35), E. S. Lee, and E. B. Meyer (deceased).

**Table IV—Associates Delinquent on July 1, 1935 and on July 1, 1936**

| | 6-Year Associates | | Associates | |
|---|---|---|---|---|
| Membership on | Number | Per Cent | Number | Per Cent |
| July 1, 1935 | 5,499 | | 4,472 | |
| Including members who owe dues to | | | | |
| May 1, 1934 | 370 | 6.7 | 373 | 8.4 |
| May 1, 1935 | 562 | 10.2 | 455 | 10.2 |
| July 1, 1936 | 5,571 | | 4,650 | |
| Including members who owe dues to | | | | |
| May 1, 1935 | 228 | 4.1 | 263 | 5.7 |
| May 1, 1936 | 485 | 8.7 | 400 | 8.6 |



## Comments Invited on ECPD Recognition Report

The report of the committee on professional recognition of Engineers' Council for Professional Development, presented at the annual meeting of that organization held on October 6, 1936, was published in the December 1936 issue of ELECTRICAL ENGINEERING, pages 1390–92, with a statement that official action by ECPD on the recommendations included in the report had been deferred pending further consideration at a future meeting, and that comments on these recommendations were invited.

This report was discussed briefly at the meeting of the AIEE board of directors held during the Institute's 1937 winter convention, and was referred to the committee on economic status of the engineer for report to the board. Professor R. W. Sorensen, California Institute of Technology, Pasadena, chairman of that committee, requests that AIEE members read the report and send their comments directly to him.

## AIEE Members Receive Eta Kappa Nu Awards

Many prominent members of the AIEE were present at a meeting of the Eta Kappa Nu Association on January 25, 1937, at New York, N. Y., when F. M. Starr (A'30) central station engineer of the General Electric Company, New York, N. Y., received the award in the 1936 Eta Kappa Nu recognition of "outstanding young electrical engineers." His name will be engraved on a trophy to be placed at AIEE headquarters; a small replica of the trophy was presented to Mr. Starr. Certificates of honorable mention were presented to P. L. Bellaschi (A'29, M'34) Westinghouse Electric & Manufacturing Company, Sharon, Pa.; E. W. Boehne (A'29) General Electric Company, Philadelphia, Pa.; A. C. Seletzky (A'29, M'35) Case School of Applied Science, Cleveland, Ohio; and C. G. Veinott (A'28, M'34) Westinghouse Electric & Manufacturing Company, Springfield, Mass. An announcement of the awards and biograph-

K. M. Winkworth

**A group at the presentation of the Eta Kappa Nu awards as "outstanding young electrical engineers"; from left to right, A. C. Seletzky and E. W. Boehne, 1936 honorable mention; F. M. Starr, 1936 winner; C. A. Faust, president of Eta Kappa Nu Association; C. G. Veinott and P. L. Bellaschi, 1936 honorable mention**

ical sketches of those receiving them were published in the January 1937 issue of ELECTRICAL ENGINEERING.

Charles F. Scott (A'92, F'25, HM'29, past-president) spoke on "Opportunity and Young Engineers," calling on F. M. Feiker (M'34) of American Engineering Council for a few words. Vladimir Karapetoff (A'03, F'12, Life Member), to illustrate his subject "Art and Culture for the Engineer," played selections on the piano. Other Institute members taking part in the ceremonies were C. A. Faust (A'35) toastmaster, R. I. Wilkinson (A'35), M. S. Mason (M'31), E. S. Lee (A'20, F'30, director), and Morris Buck (A'05, F'23).

Mr. Starr delivered an address, "Let's Take a Look at Ourselves." Other addresses were "The Young Engineer and His Success" by Mr. Bellaschi, "Engineering Appreciation" by Mr. Boehne, "Broken Bones" by Doctor Seletzky, and "Achievement, Perspective, and Balance" by Mr. Veinott. Doctor Seletzky described apparatus, developed in collaboration with Doctor W. McGaw of Western Reserve University, that is intended for use in studying the progress of "knitting" or healing of fractured bones. An inertia-operated crystal vibrator driven by an oscillator is applied to one end of the fractured member, and an inertia-operated pickup of the crystal type, connected through an amplifier to an output meter, is applied to the other end of the fractured members so that the fracture is between them. The sound-intensity measurement obtained is compared with the measurement obtained on the "symmetrical mate" of the fractured member (that is, the right leg if the left leg be the broken member), and the ratio indicates the degree of "knitting," unity being perfect. The method is said to be of exceptional value in so-called "delayed unions" where the X ray may not reveal the true condition.

**Federal Power Commission Report.** In the sixteenth annual report to Congress, submitted by Frank R. McNinch, chairman; *Basil Manly*, vice-chairman; Herbert J. Drane, Claude L. Draper, and Clyde L. Seavey, commissioners, the Federal Power Commission reports "increased activity in the various functions which have been performed for 16 years, and marked progress in the new activities entrusted to the commission by Congress in the Federal Power Act of 1935." The report, which is for the fiscal year ended June 30, 1936, and with additional activities to December 1936, consists of a 68-page paper-covered pamphlet, 6 by 9 inches, and may be obtained at 10 cents per copy from the Superintendent of Documents, Washington, D. C.

## North Eastern District to Meet in Buffalo May 5-7

Buffalo, N. Y., will be host to a 3-day meeting of the North Eastern District with headquarters in the Statler Hotel, May 5–7, 1937. Tentative arrangements indicate that an interesting program, consisting of 3 or more technical sessions, a student technical session, entertainment, and inspection trips, will take place. Arrangements are to be made for a dinner on Thursday evening with a popular lecture afterward; there will also be a dance in the hotel on that evening.

Buffalo and its environs offer opportunities for many inspection trips among a variety of industries. There are the various steel mills, the Ford Motor Company, and the Huntley station as well as several other stations of the Buffalo General Electric Company. In addition, arrangements may be made for a golf tournament, and the city offers many attractive types of amusement.

Further details will be announced when made available.

**Consulting Engineer Dies.** J. F. Max Patitz, chief consulting engineer of the Allis-Chalmers Manufacturing Company, Milwaukee, Wis., died January 3, 1937. He was associated with the company for more than 51 years, during nearly 26 of which he served as consulting engineer. Mr. Patitz was born at Mugeln, Saxony, in 1866, and entered the employ of the E. P. Allis Company in Milwaukee in 1885. In 1901, when that company became part of the Allis-Chalmers Company, he was placed in charge of the building of steam engines and compressors. Mr. Patitz began his studies of parallel operation of a-c generators as early as 1900. He also made studies of critical speeds and of vibration in high-speed machines, and was an authority on intricate mathematical calculations connected with the design of machinery. Mr. Patitz was a member of The American Society of Mechanical Engineers, the Society of Automotive Engineers, and the Verein Deutscher Ingenieure.

## Tour of European Laboratories Planned

Industrial leaders to the number of 100 from all parts of the United States are expected to participate in a tour of European scientific laboratories which is being planned by the division of engineering and industrial research of the National Research Council. An advisory committee to co-operate in the planning has been appointed.

The tour will provide an opportunity to observe methods of outstanding research laboratories in Europe representing 18 major fields, under the guidance of such organizations as the Department of Scientific and Industrial Research in England, Verein Deutscher Ingenieure in Germany, the Sorbonne in France, and others. According to present plans, the group is scheduled to sail on May 14 from New York on the S. S. "Champlain." The tour comes as the culmination of 3 highly successful educational tours made to industrial and university laboratories in the United States in 1930, 1931, and 1935, under the direction of Maurice Holland (A'23, M'30) director of the division of engineering and industrial research of NRC.

## Prizes for Papers on Arc Welding

The James F. Lincoln Arc Welding Foundation, according to information released by that newly created organization, will distribute $200,000 among the winners of 446 separate prizes for papers dealing with arc welding as a primary process of manufacture, fabrication, or construction in 11 major divisions of industry in order to stimulate intensive study of the subject. The principal prize winner will receive not less than $13,700. Other prizes range from $7,500 to $100, the latter sum to be awarded each of 178 contestants who receive no other prize but whose papers are adjudged worthy of honorable mention.

In order to assure equal competitive opportunity, similar prizes are offered in the 11 major divisions of industry covered by the contest. These divisions are: automotive, aircraft, railroad, watercraft, structural, furniture and fixtures, commercial welding, containers, welderies, functional machinery, and industrial machinery. Wide diversification of awards is effected by further dividing each major industry into various subclassifications; with entrants required to select in advance the particular

subclassification to which their papers will relate.

When accepted by the jury of awards as properly classified, each paper will be in competition, in its particular subclassification, for 5 initial prizes established for that group. These are worth, respectively, $700, $500, $300, $200, and $100. From among these subclassification winners 4 papers will be selected in each major industry to receive additional prizes of $3,000, $2,000, $1,000, and $800. Thus these 44 semifinalists will be awarded a total of $74,800. In addition, the semifinal winners in the various divisions will be considered as possible recipients of the 4 main prizes. These range from $10,000 to $3,500, with the winner of the grand prize receiving not less than $13,700 for his paper.

Contestants, it has been announced, must have papers in duplicate on file with the secretary of the foundation at Cleveland, Ohio, not later than June 1, 1938. Prospective entrants should communicate promptly with A. F. Davis, box 5728, Cleveland, for complete details of the rules and conditions covering awards.

# Standards

## Proposed Standards for Transformers

The sectional committee on transformers working under the rules of procedure of the American Standards Association has practically completed its work in drawing up a new set of standards for transformers, regulators, and other induction apparatus, according to V. M. Montsinger, chairman of the AIEE standards committee. These will be submitted to the sectional committee for final approval in the near future.

These new standards, having as their basis the present AIEE Standards No. 13, have incorporated in them not only the latest practices but a considerable amount of material from standards of the National Electrical Manufacturers Association. In the appendixes have been placed a new set of guides for the operation of transformers, a development of the AIEE recommendations on operation giving for the first time permissible short-time overloads for both power and distribution transformers. Also, an enlarged and revised test code for transformers will be included in an appendix.

It is planned after approval by the committee and the ASA to publish these as American Tentative Standards for distribution to all interested societies for comments and suggestions for improvement before they are published as final American Standards. It is expected that the tentative drafts will be published within the next few months.

**Test Code for Synchronous Machines.** An extensive revision of the "Preliminary Report on a Proposed Test Code for Synchronous Machines" came up for general discussion at one of the informal conferences held during the recent winter convention of the Institute. Copies are now available in pamphlet form and can be obtained gratis by writing H. E. Farrer, secretary AIEE standards committee, 33 West 39th Street, New York, N. Y. The AIEE committee on electrical machinery under whose auspices all of the test codes on rotating machinery are being developed hopes, as a result of the open discussion of the report at the conference and possible criticisms which may develop through wide circulation of the printed pamphlet, to be able shortly to make available a final approved synchronous code satisfactory to all.

**Test Code for D-C Machines.** At the same informal conference at which the synchronous code referred to in the preceding paragraph was discussed, there was also presented a preliminary draft of a proposed "Test Code for D-C Machines." This has not yet reached the stage where it is ready for general distribution in printed pamphlet form as several important points are still open to argument. As soon as these are cleared up, publication will take place and copies will then be available to all for further criticism and suggestion.

**Test Code for Induction Machines.** The second step toward the development of a finally approved "Test Code for Induction Machines" was also taken at the winter convention conference to which previous reference has been made. This code first appeared in preliminary report form in December 1934. When the revised and approved code will become available is impossible to predict just at present, but it is expected that the electrical machinery committee will shortly be in a position to ask the approval of the standards committee of this induction machinery code.

**Test Code for Sound Level Measurements.** At the meeting on January 25, 1937, of the standards committee a report was received from P. L. Alger, chairman of its subcommittee on sound, advising that the subcommittee is preparing a "Test Code for Sound Level Measurements on Apparatus." It is intended for use as a guide in the measurement of sound levels and the investigation of the various elements that contribute to the total noise produced. The standards committee agreed to issue the code in pamphlet form when completed.

**Rotation, Connections, and Terminal Markings for Electric Power Apparatus.** A new American Standard for "Rotation, Connections, and Terminal Markings for Electric Power Apparatus" has just been issued in pamphlet form by the National Electrical Manufacturers Association, the sponsor organization. This project, known as *C*–6, has been going forward in a sectional committee working under the rules of procedure of the American Standards Association, the Institute being one of the organizations represented on the committee. The first edition of the standard received approval in 1925 and this revision was approved by American Standards Association in June 1936. Copies of the standard may be obtained at 90 cents each by addressing National Electrical Manufacturers Association, 155 East 44th Street, New York, N. Y.

**Revised Dry Cell Standards.** A revision of "Specifications for Dry Cells and Batteries," approved as an American Standard in 1930 and issued as "Bureau of Standards Circular 390," has just been approved by the American Standards Association. The new edition will be issued shortly by the sponsor, the Bureau of Standards, under the official designation of *C* 18–1937.

**Proposed Revision of National Electrical Safety Code.** The National Bureau of Standards, the sponsor under ASA procedure for the sectional committee on national electrical safety code, is taking the preliminary steps calling for a reorganization of the committee which when completed will consider a revision of the safety code as approved by ASA in 1927.

**Proposal for International Standardization of Photometric Units.** The National Bureau of Standards will propose in the near future the international adoption of fundamental photometric units which, if adopted, will involve a slight change in the units in use in this country. Essentially the proposal will be as follows: That the primary standard of light shall be the black body radiator operated at the temperature of solidification of pure platinum; that the brightness of the primary standard shall be taken as 60 candles per square centimeter, thus fixing the magnitude of the unit of intensity, the candle, for the color of light given by the primary standard; that standards for light of colors different from that of the primary standard shall be established by applying the "visibility factors" which have been adopted by the Illuminating Engineering Society, the American Standards Association, the International Commission on Illumination, and the International Committee on Heights and Measures. The Institute will appoint a representative on the subcommittee which will consider the full proposal and its effect upon American practice.

**Power and Rate Terms.** There has just been issued by the Federal Power Commission, Electric Rate Survey, a "Glossary of Important Power and Rate Terms, Abbreviations, and Units of Measurement." This pamphlet, which should be of considerable interest to those in the power generation field, has as its purpose the development of a uniform terminology for the reports and correspondence of the commission. Quite a number of the definitions of electrotechnical terms appearing in the glossary have been developed in co-operation with the interested subcommittees of the sectional committee on electrical definitions, of which the Institute is sponsor. Copies of the glossary may be obtained from the Superintendent of Documents, Washington, D. C., at 5 cents each.

# Letters to the Editor

CONTRIBUTIONS to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or reject them entirely.

ALL letters submitted for consideration should be the original typewritten copy, double spaced. Any illustrations submitted should be in duplicate, one copy, to be an inked drawing but without lettering, and other to be lettered. Captions should be furnished for all illustrations.

STATEMENTS in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Effective Resistance of Synchronous Machines

*To the Editor:*

It is well known that the effective resistance of a synchronous machine is greater than the d-c resistance due to eddy current and hysteresis losses caused by the armature leakage flux, proximity effects due to armature current, and additional losses due to the distortion of flux under load. An approximate value of these losses may be obtained from the short-circuit loss and the armature $I^2R_{dc}$ loss.[1] This method gives values which are too low, since under dead short circuit, the flux in the machine is small. Robertson[2] gives a complete discussion of the subject, and his figures 1 and 2 show the errors to be expected. In computing the machine efficiency, it is customary to make an approximate correction in which the core loss is taken corresponding to the internal voltage.[1] It is the writer's opinion that more accurate results will be obtained using the effective resistance determined from the V-curve test,[3] and an improved method which includes the increase in core loss under load will be described in the paragraphs following.

The effective armature resistance is defined as the ratio of the power per phase consumed in the armature windings to the square of the current. The power (using the per unit system throughout) consumed with the motor running light and all shaft load disconnected, may be expressed:

$$P = I^2R + b$$

where

$P$ = power consumed with machine running light

$I$ = armature current

$b$ = sum of constant losses (windage, friction, and iron)

$R$ = effective armature resistance

With the machine terminal voltage held constant, values of total power and armature current are obtained by varying the field current. The curves of figure 1 of this letter show typical results obtained from a 3-phase 6-pole 15-kva 1,200-rpm 220-volt 39.4-ampere generator. The power was measured by the 2-wattmeter method.

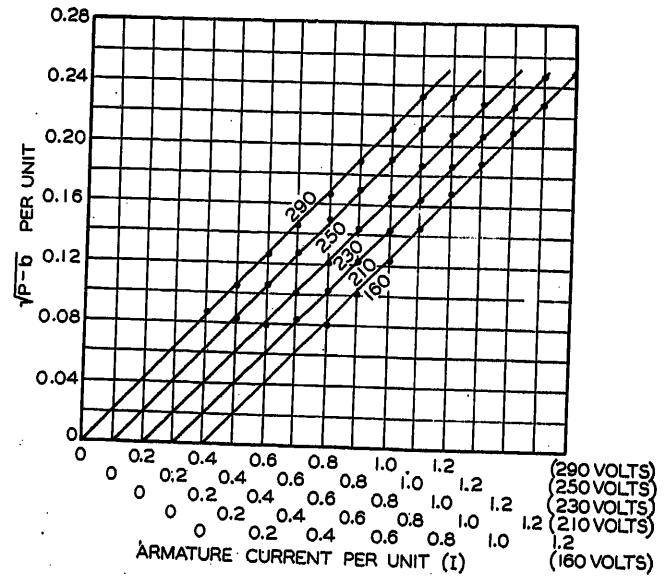


**Fig. 2. Determination of effective armature resistance**

Terminal voltages held constant at values shown on curves

Subscripts will be used to refer to 2 widely separated points on the same power-current curve.

$$P_1 = I_1^2R + b \qquad P_2 = I_2^2R + b$$

Solving for the constant losses

$$b = (I_1^2P_2 - I_2^2P_1)/(I_1^2 - I_2^2)$$

Transposing the original equation and taking the square root gives

$$\sqrt{P - b} = I\sqrt{R}$$

Values of $\sqrt{P - b}$ and $I$ were plotted to give straight lines passing through the origin; see figure 2. For a given terminal voltage, the effective resistance equals the square of the slope of the line.

The method is simple and effective, as the constant losses are evaluated without difficulty. If the value of $b$ is larger than the correct value, the curve will depart from a straight line and be concave downward, while if it is smaller than the correct value the converse will be true. The value $b$ can be conveniently corrected by plotting 2 widely separated points on the $\sqrt{P - b}$ versus $I$ curve. A straight line is drawn connecting the larger value with the origin. If the second point does not fall on this line, $b$ can be changed slightly to make it do so.

The method assumes that the effective resistance is constant and independent of current. The correctness of this assumption is verified by an examination of the drift of points from the $\sqrt{P - b}$ versus $I$

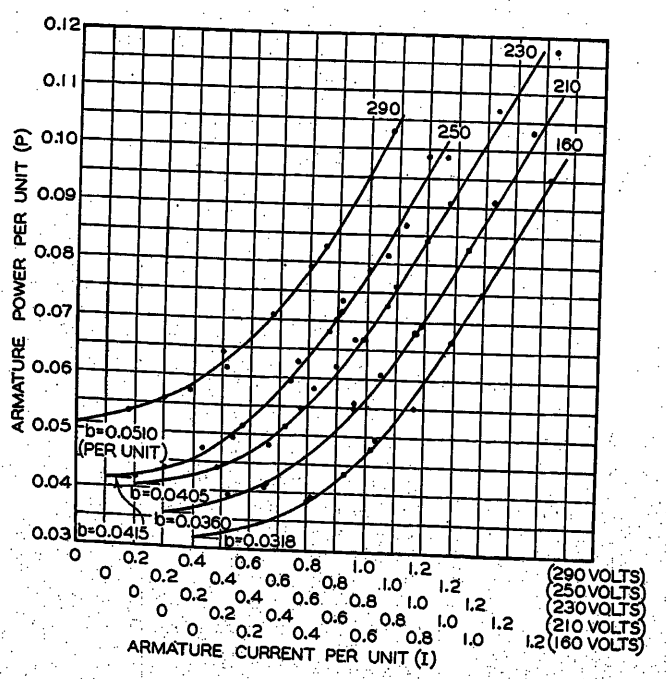

**Fig. 1. Determination of effective armature resistance**

Terminal voltages held constant at values shown on curves

curve. The results for 5 independent tests at various terminal voltages indicate that there is no appreciable variation with voltage. The effective resistance was taken as the average value, $R = 0.044$.

The ohmic resistance of the armature winding was determined by the d-c volt-ammeter method. The average resistance was $R_{dc} = 0.035$. It is apparent that the stray losses may be expressed as a resistance.

If it is desired to determine the machine performance at temperatures different from test, the corrected effective resistance is found as follows:

$$R_s = R_{t0} - R_{dct0} \quad \text{and} \quad R_{t1} = R_s + R_{dct1}$$

in which

$R_{t0}$ = effective resistance at temperature $t_0$
$R_{t1}$ = effective resistance at temperature $t_1$
$R_{dct0}$ = ohmic resistance at temperature $t0$
$R_{dct1}$ = ohmic resistance at temperature $t1$
$R_s$ = stray losses expressed as a resistance.

In using this method, the core loss should be taken corresponding to the terminal voltage, since the variation in core loss is taken into account in the effective resistance. It is believed that this method of determining the effective resistance is more accurate than the conventional procedure of determining the d-c resistance and the stray load losses from a short circuit test, since the additional losses due to flux distortion, and the increase in core loss under load, are taken into account. The advantages of the method are that the effective resistance may be considered constant for most practical cases, and may be inserted directly in the vector diagram, hence simplifying the analysis.

Instructor in Electrical Engineering,
University of California, Berkeley

## ASA Formula for 2-Winding Transformer Regulation

*To the Editor:*

I should like to submit the following as a derivation for the ASA equation for regulation of a 2-winding transformer. The notation used is the same as that used by J. E. Clem, page 466 of the May 1936 issue of ELECTRICAL ENGINEERING, in the paper "An Exact Formula for Transformer Regulation."

From figure 1 of this letter,

$$E_p = \sqrt{(E_s \cos\theta + IR)^2 + (E_s \sin\theta + IX)^2}$$

Dividing each side of the equation by $E_s$ gives

$$\frac{E_p}{E_s} = \sqrt{(m + r)^2 + (n + x)^2}$$

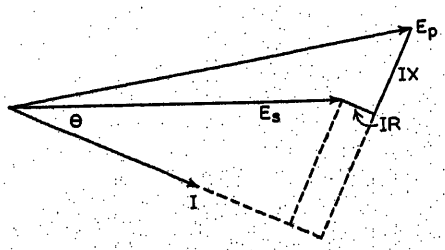

Fig. 1. Vector diagram

where $r = IR/E_s$ and $x = IX/E_s$

Per cent regulation =

$$\left[\frac{E_p - E_s}{E_s}\right] \times 100 = \left[\frac{E_p}{E_s} - 1\right] \times 100$$

$$= \left[\sqrt{(m + r)^2 + (n + x)^2} - 1\right] \times 100$$

Very truly yours,
JOHN D. SCARBOROUGH (Enrolled Student)
Michigan College of Mining and Technology, Houghton

# Personal Items

## W. H. Harrison Nominated for Presidency

WILLIAM HENRY HARRISON (A'20, M'30, F'31, vice-president) assistant vice-president, department of operation and engineering, American Telephone and Telegraph Company, New York, N. Y., has been nominated for the presidency of the AIEE for the 1937–38 term. Mr. Harrison was born June 11, 1892, at Brooklyn, N. Y., and was graduated in industrial electrical engineering at Pratt Institute in 1915. He entered the employ of the New York Telephone Company in 1909, where his work until 1915 included apparatus inspection, assembling, and wiring. From 1915 to 1919 he was engaged in telephone circuit design in the engineering department of the Western Electric Company, and in 1919 he became a member of the engineering staff of the American Telephone and Telegraph Company. In 1924 Mr. Harrison was made equipment and building engineer with general supervision of the engineering of the subscribers station and central office plant of the Bell Telephone System, and in 1929 he became plant engineer, with broadened responsibilities including general direction of the engineering, design, and layout of all departments of the Bell System plant, including system relations with other wire-using utilities. In 1933 Mr. Harrison was elected vice-president in charge of operations of The Bell Telephone Company of Pennsylvania and The Diamond State Telephone Company of Delaware, with headquarters in Philadelphia, Pa. He was appointed assistant vice-president in the department of operation and engineering in 1937. Mr. Harrison has a long record of active service in the Institute; he is at present vice-president representing the AIEE Middle Eastern District (number 2) and a member of the executive committee (1936–37) and committees on legislation affecting the engineering profession, 1932–37; Edison Medal, 1935–37; and Lamme Medal, 1935–38. In addition, he is a member of the special committee to consider Associate dues and related matters and the committee on revision of Section territories, and has been a member of the following technical committees: communication, 1935–36; technical program, 1929–36 (chairman 1931–33); co-ordination of Institute activities, 1931–33; publication, 1931–33; award of Institute prizes, 1931–34 (chairman 1931–33); and popular science award, 1931–34. Mr. Harrison also was a member of the AIEE national nominating committee in 1935, and was an AIEE representative on the Alfred Noble Prize committee of the American Society of Civil Engineers (1932–34) and on the American committee on marking of obstructions to air navigation during 1932–33.

## Vice-Presidential Nominees are Jollyman, McClellan, Mc Henry, Stein, Wood

JOSIAH PICKARD JOLLYMAN (A'05, M'25, F'30) chief of the division of hydroelectric and transmission engineering, Pacific Gas and Electric Company, San Francisco, Calif., has been nominated to serve the Institute as vice-president representing the Pacific District (number 8). Mr. Jollyman was born at Santa Barbara, Calif., October 29, 1879, and received the degree of bachelor of arts in electrical engineering at Stanford University in 1903. From 1903 to 1909 he was employed by the California Gas and Electric Corporation as an electrician and as superintendent of electrical construction. In 1909 he became electrical engineer for the Great Western Power Company of California, where he remained until he joined the engineering staff of the Pacific Gas and Electric Company in 1911. Since 1920 Mr. Jollyman has been chief of the division of hydroelectric and transmission engineering, in which position he has had charge of the electrical and mechanical design of 11 hydroelectric plants and the electrical design of several transmission lines and substations of large capacity. Mr. Jollyman has presented before the Institute several papers on transmission engineering subjects and has been a member of the committees on power stations (now power generation), 1923–24; and power transmission and distribution, 1915–17, 1923–29, 1930–37. He has been active in the affairs of the San Francisco Section, and was chairman of that Section during 1920–21.

LESLIE NEWMAN MCCLELLAN (A'14, M'26) chief electrical engineer, United States Bureau of Reclamation, Denver, Colo., has been nominated to serve the Institute as vice-president representing the North Central District (number 6). He was born at Middletown, Ohio, March 27, 1888, and received the degree of bachelor of science in electrical engineering in 1911 from the University of Southern California. He was then employed by the United States Reclamation Service at Phoenix, Ariz., on the Salt River project as electrical assistant, 1911–13; junior engineer, 1913–14; assistant engineer, 1914–15; and engineer in responsible charge of construction and operation of the power system, 1915–17. During 1917–18 he served overseas as a lieutenant in the United States Army Engineer Corps, upon his return becoming electrical engineer in the office of the chief engineer of the Reclamation Service at Denver, where he was engaged in the design of power plants, substations, and transmission lines. Mr. McClellan was employed by the Southern California Edison Company as engineer in the transmission department during 1923–24. Since 1924 he has held his present position as chief electrical engineer for the Bureau of Reclamation at Denver, where he has responsible charge of design, construction, and operation of power and pumping plants, substations, and transmission lines on the various reclamation projects of the Federal Government. Mr. McClellan is the author of papers on the Boulder Dam project published by the Institute, and was a member of the power transmission and distribution committee 1933–36.

MORRIS JAMES MC HENRY (A'11, M'20) district manager of the Canadian General Electric Company, Toronto, Ont., Canada, has been nominated to serve the Institute as vice-president representing the Canada District (number 10). Mr. Mc Henry was born at Catasauqua, Pa., August 7, 1888, and received the degree of bachelor of science in electrical engineering at McGill University in 1910. Following his graduation, and until 1912, he was employed by Smith, Kerry, and Chase, consulting engineers, Toronto, in power station design and field engineering. In 1912 he was employed by the Canadian General Electric Company as sales engineer in Toronto, and in 1916 became assistant manager of apparatus sales in the Toronto district. In 1918 Mr. Mc Henry accepted a position as manager and secretary-treasurer of the Walkerville Hydro-Electric System, and remained as chief executive of that system until 1924. In that year he became sales manager of the Ferranti Electric Company, Ltd., which position he relinquished in 1926 to become manager of the United States sales department of the Canadian General Electric Company. In 1930 he was appointed district manager for Ontario. Mr. Mc Henry has served the Institute as a member of the committee on industrial and domestic power during 1921–22, and has been active in local Institute affairs. In the Toronto Section he has served as director (1924) and chairman (1935–36), and as chairman of the Section committees on membership (1925) and papers (1926). Mr. Mc Henry is a past-president of the Association of Municipal Electric Utilities of Ontario and a member of the Association of Professional Engineers of Ontario, having served as a member of the board of governors of that organization during 1924 and 1925. He is president of the Electric Club of Toronto and president of the Electric Service League of Toronto.

IRVING MELVILLE STEIN (A'18, M'27) director of research for Leeds and Northrup Company, Philadelphia, Pa., has been nominated to serve the Institute as vice-president representing the Middle Eastern District (number 2). Mr. Stein was born at Long Branch, N. J., March 20, 1894, and obtained his technical education from the New York Edison evening technical school, Columbia University extension course, and Fort Wayne Correspondence School. He was employed in the meter department of the New York (N. Y.) Edison Company in 1911, and the following year was transferred to the standardizing laboratory. During 1913 he was in charge of the rehabilitation work on instruments damaged in the flood at Dayton, Ohio, then returned to the test department of the Edison company. In 1916 he was made assistant foreman of the standardizing laboratory, and the following year was made foreman. During this time he was also engaged in work on protective relays. During 1918 he was senior inspector in the eastern department of the U.S. Signal Corps, and also worked as personal assistant to Thomas A. Edison in the development of submarine and airplane locating devices. He was engaged by the Leeds and Northrup Company as sales engineer in 1919, and 2 years later was given charge of general division sales. In 1924 he was made assistant sales manager and in 1927 was given charge of development, engineering, production, publicity, and sales of combustion control apparatus. He is now director of research and a member of the executive committee of the company. Mr. Stein is the author of numerous technical articles. He has been a member of the Institute's publication committee since 1934 (chairman 1936–37), of the committee on coordination of Institute activities since 1933, and of the Sections committee since 1929, serving as chairman 1933–36. He served on the membership committee 1926–27 and 1931–33, and for 1936–37 has been appointed a member of the committees on technical program and award of Institute prizes. Among other organizations of which Mr. Stein is a member may be included the American Physical Society, American Chemical Society, American Electrochemical Society, Illuminating Engineering Society, Franklin Institute, and American Society for Testing Materials.

EDWIN DOW WOOD (A'21, M'26) general superintendent of the Louisville Gas & Electric Company, Louisville, Ky., has been nominated to serve the Institute as vice-president representing the Southern District (number 4). Mr. Wood was born at Montevideo, Uruguay, April 17, 1878, and attended high school at Callao, Peru. In 1903 he received the degree of bachelor of science at De Pauw University, Greencastle, Ind., and entered the employ of the Union Traction Company of Indiana. During the next year he was employed by the Pope-Waverly Electric Company of Indianapolis, Ind., and the General Electric Company at Schenectady, N. Y., for short periods before he joined the Empresa Electrica Santa Rosa at Lima, Peru, later the Empresas Electricas Asociadas. He became assistant chief engineer in charge of power plants for this company, and was acting chief engineer when he resigned in 1909 to become construction department foreman for the General Electric Company at Schenectady, N. Y. In the following year he was transferred to the engineering department in the Cincinnati, Ohio, district, where he was engaged in general power house and substation engineering work. Mr. Wood accepted the position of electrical operating engineer with the Louisville Gas & Electric Company in 1915, and was electrical engineer from 1926 to 1932, being appointed general superintendent in the latter year. In 1936 he was made a director of the company. Mr. Wood is a past-president of the Engineers and Architects Club of Louisville and a past-chairman of the Louisville Section, and until its dissolution was a member of the electrical apparatus committee of the former National Electric Light Association. He is co-author of an Institute paper published in 1931.

## Bush, Beardsley, Lane
### Nominated for Institute Directorships

VANNEVAR BUSH (A'15, M'19, F'24, Lamme Medalist '35) vice-president of Massachusetts Institute of Technology and dean of the school of engineering, Cambridge, Mass., has been nominated to serve the AIEE as a member of its board of directors. Doctor Bush was born at Everett, Mass., March 11, 1890. In 1913 he was graduated from Tufts College, and in 1916 was awarded the degree of doctor of engineering from Massachusetts Institute of Technology and Harvard University. In 1932 he received the honorary degree of doctor of science from Tufts College, and he is now a member of the board of trustees of that college. Following graduation from Tufts College he entered the testing department of the General Electric Company, and the next year was an instructor in mathematics at Tufts College. In 1915 he engaged in graduate study at M.I.T., and the following year returned to Tufts as assistant professor of electrical engineering. During 1917–18 Doctor Bush carried on research work in submarine detection for the United States Navy; then until 1923 was associate professor of electric power transmission at M.I.T. From 1917 to 1922 he was also consulting engineer for the American Radio and Research Corporation. In 1923 he was appointed professor of electric power transmission, holding this title until appointed to his present position in 1932. Doctor Bush long has been interested in the design of analyzing instruments and is internationally known for his achievements in this field. For one development he was awarded the Levy Medal of the Franklin Institute in 1928, and he received the AIEE Lamme Medal for 1935. Doctor Bush is a director

of the Spencer Thermostat Company and of Raytheon, Inc., and is a member of the corporation of Massachusetts Institute of Technology. He is the author of many technical articles and of "Operational Circuit Analysis," and, jointly with W. H. Timbie (A'10, F'24), of "Principles of Electrical Engineering." The Institute committees on which he has served include research (1924–30); electrophysics (1924–33, chairman 1931–33); power transmission and distribution (1925–27, 1928–29); education (1928–29); and technical program (1929–33). He is now a member of the Edison Medal and Lamme Medal committees, and representative on the division of engineering and industrial research of National Research Council. Doctor Bush is a fellow of the American Academy of Arts and Sciences and American Physical Society, and a member of the Society for the Promotion of Engineering Education, National Academy of Sciences, Phi Beta Kappa, Alpha Tau Omega, Sigma Xi, and Tau Beta Pi.

CLIFFORD RAY BEARDSLEY (A'08, M'20, F'30) superintendent of distribution, Brooklyn Edison Company, Brooklyn, N. Y., has been nominated to serve the Institute as a member of its board of directors. He was born at Bridgeport, Conn., December 19, 1885, and attended the Sheffield Scientific School of Yale University, from which he received the degree of bachelor of philosophy in electrical engineering in 1905. He then entered the testing department of the General Electric Company at Schenectady, N. Y., and subsequently was assigned to the offices at New York, N. Y., and New Haven, Conn. In 1911 he became sales agent for the United Illuminating Company at Bridgeport, where he had charge of sales, construction, and installation of factory electrifications. Seven years later he accepted the position of electrical engineer with Fred T. Ley & Company, Springfield, Mass., in which position he had charge of design and installation of power station and industrial electrical work, being concerned mostly with hydroelectric and steam plants and transmission lines. Mr. Beardsley accepted in 1923 the position with the Brooklyn Edison Company of electrical construction engineer in charge of inside-plant electrical construction in power stations, substations, and consumer vaults. In 1932 he was appointed assistant to the superintendent of distribution, and recently was advanced to the position of superintendent of distribution. During 1928–30 Mr. Beardsley was chairman of the accident prevention committee of the former National Electric Light Association, and he has served as chairman of the committees for the 1936 and 1937 winter conventions of the Institute. He has written numerous articles on the relation of engineering to safety.

FRANCIS HOWARD LANE (M'23) manager of the engineering division of the Public Utility Engineering and Service Corporation, Chicago, Ill., has been nominated to serve the Institute as a member of its board of directors. He was born at St. Louis, Mo., June 7, 1882, and studied electrical engineering at Lewis Institute, Chicago, Ill., from which he received the degree of mechanical engineer in 1904. He then entered the employ of H. M. Byllesby and Company as draftsman, and subsequently was engaged in preliminary investigations of projects, and construction. From 1910 to 1915 he was engaged in general investigations and appraisals of public-utility properties, and during 1915–17 was manager of the department of examinations and reports. Mr. Lane was made manager of engineering and construction of Byllesby Engineering and Management Corporation in 1917, and held this position continuously until the formation of the successor company, Public Utility Engineering and Management Corporation, in 1936, with which he assumed a similar position. He is a member of The American Society of Mechanical Engineers and the Western Society of Engineers.

### W. I. Slichter
### Renominated as Institute Treasurer

WALTER IRVINE SLICHTER (A'00, M'03, F'12, national treasurer, member for life) professor and head of the department of electrical engineering at Columbia University, New York, N. Y., has been nominated to succeed himself as treasurer of the Institute. Professor Slichter was born at St. Paul, Minnesota, May 7, 1873, and was graduated at Columbia University in 1896 with the degree of electrical engineer. He entered the employ of the General Electric Company as a student in July 1896, and the following year was transferred to the office of Doctor C. P. Steinmetz, where he was engaged for a year in carrying on experimental work, tests, and calculations on various subjects. During the following 2 years, he was engaged in designing induction motors, alternators, rotary converters, transformers, and special experimental apparatus. For a number of years thereafter he devoted most of his time to the design of electrical machinery and, more particularly, the equipment of electric railways. In 1910 he was appointed professor of electrical engineering and head of that department at Columbia University, which position he still fills. During the war he was civilian director of the Air Service school for radio officers at Columbia University. Since 1914, Professor Slichter has devoted considerable time to instruction in electrical engineering to naval officers of the postgraduate school of the United States Navy. National treasurer since 1930, he was a member of the board of directors of the Institute from 1918 to 1922 and vice-president from 1922 and 1924, and served on the following committees: board's committee on technical activities, 1918–20; board of examiners, 1915–18 and 1924–28; co-ordination of Institute activities, 1920–24 and 1925–27; editing (later publication) 1914–21; education, 1916–20; executive, 1919–24; meetings and papers (now technical program) 1917–24; industrial and domestic power (now general power applications) 1922–23; finance, 1923–24; standards, 1923–26; legislation affecting the engineering profession, 1931–36 (chairman 1933–35); Iwadare foundation, 1931–33; and special committee on model registration law, 1933–34. He was also Institute representative on the United States National Committee of the International Electrotechnical Commission, 1928–32. Professor Slichter is now serving as chairman of the committee on Columbia University scholarships, of which he has been a member since 1922 and chairman since 1925, and as a member of the committees on constitution and by-laws (1925–28 and 1930 to the present; chairman 1925–27), Edison Medal (1918–22 and 1930 to the present), and electrical machinery (1934 to the present). In addition, he has been a representative on the library board of United Engineering Trustees, Inc., since 1915, Engineering Foundation board since 1930, engineering societies monographs committee since 1930, and advisory board of the National Bureau of Engineering Registration since 1933. Professor Slichter is the author of many articles on technical subjects, and has presented several papers and discussions before the Institute. He is a member of The American Society of Mechanical Engineers, Society for the Promotion of Engineering Education, and other organizations.

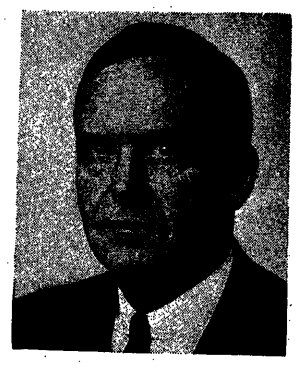
## Frank Conrad to Receive Lamme Medal

FRANK CONRAD (A'02, Edison Medalist '30) assistant chief engineer of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has been awarded the Lamme Medal of the AIEE for 1936 " for his pioneering and basic developments in the fields of electric metering and protective systems." Doctor Conrad was

FRANK CONRAD

born at Pittsburgh, Pa., May 4, 1874, and joined the Westinghouse organization in 1890. In a short time he was transferred to the experimental and testing department, and in 1897 designed the so-called round type of watt-hour meter, which was smaller and more efficient than the previous square types. He then started the systematic redesign of all meters and instruments, which led to improvements in efficiency and the development of new types, among which were the relay-operated recording meter, power factor meter, electrostatic voltmeter, and ground detector. In 1904 Doctor Conrad was appointed general engineer, and for many years served as assistant to the vice-president in charge of engineering. He was appointed assistant chief engineer in 1921. About 1910 Doctor Conrad started the development of a complete elec-

trical system for automobiles, including in his designs voltage-regulated generators such as have come into universal use in the automobile industry in 1937. In 1912 he began investigations into radio telegraphy and telephony, designing and building radio transmitting and receiving equipment. Problems of power distribution for a-c railway systems also engaged his attention at this time. During the World War he aided in the production of telephone and telegraph equipment for the United States Army and Navy, and also designed grenades and grenade-throwing devices. Following the war he sent programs over the air from radio transmitters, and the equipment used by KDKA when that station began broadcasting in 1920 was designed by him. His investigations led to improved apparatus, and to a study of the short-wave field in which he sensed new possibilities. Other work in which he has been engaged includes units for household refrigerating purposes and electric clocks. Doctor Conrad is well-informed in biology, astronomy, and botany. In 1928 he was given the honorary degree of doctor of science by the University of Pittsburgh. Other awards he has received are the Morris Liebmann prize of the Institute of Radio Engineers in 1925, the Edison Medal of the AIEE in 1930, and the John Scott Medal of the City of Philadelphia in 1933. He is a fellow of the Institute of Radio Engineers and a member of the Society of Automotive Engineers and the American Association for the Advancement of Science, and holds the rank of lieutenant commander in the United States Naval Reserve.



H. H. BEVERAGE (A'23, M'34) chief research engineer, R.C.A. Communications, Inc., New York, N. Y., recently was elected president of the Institute of Radio Engineers for the year 1937. Mr. Beverage was born October 14, 1893, at North Haven, Me., and was graduated from the University of Maine in 1915 with the degree of bachelor

H. H. BEVERAGE

of science in electrical engineering. Upon graduation he was engaged by the General Electric Company, Schenectady, N. Y., as a test engineer, but in 1916 was transferred to the radio laboratories of that company as assistant to Doctor E. F. W. Alexanderson (A'04, F'20). In 1920 Mr. Beverage accepted a position with the Radio Corporation of America, where he was placed in charge of radio research on communication equipment, and continued there until 1929, when he was transferred to R.C.A. Communications, Inc., as chief communications engineer. He has been chief research engineer since 1932. Mr. Beverage has distinguished himself in his research on aperiodic directive receiving antenna systems and receiving systems for reducing the effects of fading at high frequencies. He is the holder of several patents on communication devices and systems, and in 1923 was awarded the Morris Liebmann Memorial Prize of the Institute of Radio Engineers for his research work on directive antenna systems. He is author or co-author of many papers on communication subjects, including 2 papers presented before the Institute, and is at present a member of the Institute's committee on communication. Mr. Beverage is a fellow of the Radio Club of America.

J. H. PAYNE (A'12, M'32) formerly with the Westinghouse International Company, recently was appointed chief of the electrical division of the Bureau of Foreign and Domestic Commerce, United States Department of Commerce, Washington, D. C. Mr. Payne was born June 24, 1883, at Titusville, Pa., and was graduated from Armour Institute of Technology with the degree of bachelor of science in electrical engineering in 1905. Immediately following his graduation, he entered the employ of the Westing-

J. H. PAYNE

house Electric & Manufacturing Company, East Pittsburgh, Pa., being engaged first in engineering and construction work and later in the sales department at New York, N. Y. From 1915 to 1919 Mr. Payne had charge of a division making sales to mining companies. In 1920 he was transferred to the Westinghouse International Company and placed in charge of the selection and appointment of all of that company's distributors; later, he was made manager of the company's department of Europe, in which capacity he was in charge of the company's business in Europe and the dependencies of European countries. In 1929 he was appointed manager of the power department, in charge of the company's sales of central station and distribution equipment in all countries except the United States and Canada. Mr. Payne's duties with the Westinghouse International Company required extensive traveling in the United States and in 31 foreign countries.

W. H. LAWRENCE (A'99, M'12, member for life) chief operating engineer, The New York, (N. Y.) Edison Company, Inc., has retired. Mr. Lawrence was born February 28, 1870, at Middletown, Ohio. He entered the electrical industry in 1886, being employed as an apprentice for the General Electric Company, Schenectady, N. Y. After one year with that company, he became associated with the Edison Manufacturing Company at New York and soon thereafter filled the position of assistant superintendent of construction in the western offices of that company at Cincinnati, Ohio. He continued to serve in that capacity after the consolidation of the Edison and Thomson-Houston companies with the Central Thomson-Houston Company, but in 1889 was transferred to the Edison Electric Illuminating Company of New York. That company has since become The New York Edison Company, Inc., and Mr. Lawrence had completed 47 years of continuous service with the company at the time of his retirement. He is the author of several articles on station operation, including one paper presented before the Institute. He served the Institute as a member of the committee on power generation during the period 1920–29. Mr. Lawrence is a member of The American Society of Mechanical Engineers.

L. E. EMERICH (A'24) who has been district manager of technical division sales in the Chicago, Ill., offices of the Leeds & Northrup Company, has been transferred to the Philadelphia, Pa., offices of that company as assistant sales manager in the technical sales division. Mr. Emerich was born at Schuylkill Haven, Pa., in 1898, and received the degree of bachelor of science at Carnegie Institute. After serving briefly with the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., and the Public Service Electric and Gas Company, Newark, N. J., he entered the sales department of the Leeds & Northrup Company at Philadelphia in 1923 and since then has been associated with that company continuously.

D. G. EVANS (A'20) assistant general manager of the Wisconsin Gas and Electric Company, Racine, has been appointed general manager. Mr. Evans was born at Larned, Kans., in 1887, and received the degree of bachelor of science in electrical engineering at the University of Illinois in 1917. Following a brief service as transformer test engineer for the Wagner Electrical Manufacturing Company, he entered the employ of the Wisconsin Gas and Electric Company as an engineer in 1919. His service with that company has been without interruption.

J. R. READ (A'04) who has been district manager for the Canadian Westinghouse Company, Ltd., at Vancouver, B. C., Can., has been appointed vice-president of the company with headquarters at Hamilton, Ont. Mr. Read was born October 24, 1879, in Virginia. His early electrical experience was gained with the Westinghouse Electric & Manufacturing Company at East Pittsburgh, Pa. In 1901 he was engaged as con-

sulting electrician for various gold-dredging companies in California, and later he became electrical engineer for the Northern California Power Company at Redding. His Canadian experience began in 1904 with his engagement as district-office sales engineer for the Vancouver district office of the Canadian Westinghouse Company. In 1908 he was appointed district manager, and since that time has been associated with many important projects.

G. G. POST (A'11, F'33, past vice-president) vice-president in charge of power, Milwaukee Electric Railway & Light Company, Milwaukee, Wis., has been appointed a representative of the Institute upon the Commission of Washington Award to fill an unexpired term ending August 1, 1938. Mr. Post, who was a vice-president of the Institute 1934–36, has been a member of the Institute's committee on power generation since 1932, and has served on the committees on power transmission and distribution (1922–26), protective devices (1934–36), and Edison Medal (1935–36). He has also been active on technical committees of the Association of Edison Illuminating Companies and the Edison Electric Institute.

B. L. GOODLET (A'25, M'30) research engineer for the Metropolitan-Vickers Electrical Company, Ltd., Manchester, England, recently accepted an appointment as professor in the department of electrical engineering at the University of Capetown, South Africa. Professor Goodlet, a graduate of the Imperial School (Petrograd, Russia) and the University of Sheffield (England), has been associated with the Metropolitan-Vickers company since 1922.

J. F. LINCOLN (A'08, M'20) president of the Lincoln Electric Company, Cleveland, Ohio, was honored recently by the board of directors of the company when a newly created fund and foundation for welding research was named "The James F. Lincoln Arc Welding Foundation" in recognition of his pioneer work in promoting arc welding and perfecting and developing arc-welding equipment and electrodes. Mr. Lincoln has served on several Institute committees, and was a manager 1920-24.

NATHAN COHN (A'29) for several years district manager of technical division sales for the Pacific coast, Leeds & Northrup Company, San Francisco, Calif., has been transferred to the Chicago, Ill., offices of that company in a similar capacity. Mr. Cohn is a native (1907) of Hartford, Conn., and an electrochemical engineering graduate of Massachusetts Institute of Technology. He has been associated with the Leeds & Northrup Company in its sales departments since his graduation.

C. V. ARMSTRONG (A'36) sales engineer for Ingersoll-Rand Company, New York, N. Y., has been transferred to the Chicago, Ill., offices of that company.

H. C. BROWN (A'20) formerly employed in the U.S. Engineers office, Huntington, W. Va., now is with the engineering division, World's Fair, Inc., New York, N. Y.

A. R. WELLWOOD (M'22, F'36) former director of the regional office of the Federal Power Commission, Atlanta, Ga., has been appointed supervising engineer and placed in charge of all Public Works Administration power projects in Nebraska. Mr. Wellwood has been identified with the Federal Power Commission since 1934, and formerly was director of the Commission's electric rate survey, with headquarters at Washington, D. C.

E. E. DREESE (M'25) chairman of the electrical engineering department, Ohio State University, Columbus, has been appointed a trustee of "The James F. Lincoln Arc Welding Foundation," created recently to aid welding research. Principal direction of the foundation's work will be given by him. He has been a member of the Institute's committees on education and electrophysics since 1935, and is a member of the committee on student Branches.

L. M. LA FEVER (A'26) formerly an electrical tester for the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has been transferred to the New York, N. Y., offices of that company as a field service engineer.

S. B. GAYLORD (A'36) who has been employed by the Western Public Service Company, Broken Bow, Nebr., recently accepted a position in the test engineering department of the General Electric Company, Schenectady, N. Y.

P. B. WAHLQUIST (M'29) formerly manager of the concessions department, Telefonaktiebolaget, L. M. Ericksson, Stockholm, Sweden, has accepted an appointment as general manager, Empresa de Telefonos Ericsson, Mexico City, Mexico.

I. T. MONSETH (A'26) engineering representative, Westinghouse Electric & Manufacturing Company, Kansas City, Mo., has been transferred to the St. Louis, Mo., offices of that company.

H. A. STANLEY (A'07, M'19) plant engineer of the Berkshire Fine Spinning Associates, Inc., Fall River, Mass., has been transferred to the Providence, R. I., offices of that company.

## Obituary

EDWARD BARNARD MEYER (A'05, M'13, F'27, past vice-president, past-president) chief engineer of the Public Service Electric and Gas Company, Newark, N. J., died January 31, 1937. Doctor Meyer was born October 22, 1882, at Newark. He received his technical education at the Newark Technical School, from which he was graduated in 1901; and at Pratt Institute, Brooklyn, N. Y., where he was graduated in the electrical engineering course in 1903; in 1936 he received the honorary degree of doctor of engineering from the Newark College of Engineering. Following his graduation from Pratt Institute in 1903, Doctor Meyer entered the employ of the Public Service Corporation of New Jersey as an engineering assistant, and remained with that organization and its subsidiary companies continuously until 1922. During that period he became, in 1906, field engineer in charge of underground conduit and cable system; in 1909, assistant engineer on special engineering reports, estimates, and construction work; in 1912, assistant to the chief engineer; and in 1919 assistant chief engineer. When the Public Service Production Company was formed in 1922, he was made its chief engineer. In 1929 Doctor Meyer was made a vice-president of the Public Service Production Company, and in 1930, on the occasion of the merger of that company with United Engineers and Constructors, Inc., he was appointed a vice-president of the latter corporation in the capacity of executive and engineering head of the Newark office. He was appointed chief engineer of the Public Service Electric and Gas Company in 1935. Doctor Meyer was liberal in contributing his energy and ability to the causes of the Institute; he was a director from 1928 to 1931, a vice-president during 1932–34, and president for the term 1935–36. In addition, he served on the following committees: executive, 1928–30, 1932–34, and 1935–37 (chairman 1935–36); constitution and by-laws, 1929–35 (chairman 1934–35); co-ordination of Institute activities, 1925–35 (chairman 1934–35); Edison Medal, 1927–29 and 1930–36; finance, 1927–31 and 1932–34 (chairman 1928–30, 1933–34); headquarters, 1928–30 and 1933–34; Lamme Medal, 1928–30; membership, 1924–25; award of Institute prizes, 1925–28 and 1931–34 (chairman 1925–27); publication, 1923–35 (chairman 1927–28, 1931–34); Sections, 1926–27; technical program 1918–29, 1932–34 (chairman 1925–27); transfers, 1932–35 (chairman 1932–33); power generation, 1928–32; code of principles of professional conduct, 1936–37; and power transmission and distribution, 1918–24 (chairman 1918–23). Doctor Meyer served also on the special committees on Institute policies, 1931–33; Associate dues and related matters, 1932–37; on revision of Section territories (1935–37); and biographies and talking motion pictures, 1930–33. He served as an Institute representative on the U.S. National Committee of the International Electrotechnical Commission, 1927 to 1930; the American Engineering Council, 1935–36; the Charles A. Coffin fellowship and research fund committee, 1935–36; and on the Engineering Societies monographs committee, 1930–35. He was a member of the John Fritz Medal board of award for the term 1935–39. Doctor Meyer's other technical activities included participation in the affairs of the American Standards Association, the former National Electric Light Association, The American Society of Mechanical Engineers. His numerous contributions to the technical press include a book, "Underground Transmission and Distribution."

CRANDALL ZACHARIAH ROSENCRANS (M' 36) assistant director of research, Leeds & Northrup Company, Philadelphia, Pa., died January 7, 1937. Mr. Rosencrans was born January 4, 1897, at Chicago, Ill. He received the degrees of bachelor of science in mechanical engineering (1919), master

of science in mechanical engineering (1921), and mechanical engineer (1929) at the University of Illinois, and at the time of his death had nearly completed the requirements for the degree of doctor of philosophy. Following his graduation in 1921, he was appointed to the staff of the University of Illinois Engineering Experiment Station, where he became engaged in independent research on the thermodynamics of gas and oil engines, the mechanism of explosions, and gas-engine testing. In 1926 Mr. Rosencrans accepted a position as research engineer with the Leeds & Northrup Company, and during the following 2 years was responsible for research and development work on electrical methods of gas analysis. From 1928 to 1934 he served as chief of the mechanical division and acting chief of the metallurgical division, and for one year (1928–29) as chief of the chemical division of that company's research department. He was appointed assistant director of research in 1934. Mr. Rosencrans was the holder of several patents on electrical and mechanical measuring devices, and was the author of many scientific papers and articles. He was a member of The American Society of Mechanical Engineers, American Chemical Society, Franklin Institute, Institute of Metals (British), American Society of Refrigerating Engineers, American Association for the Advancement of Science, Verein Deutscher Ingenieure (German), Sigma Xi, and Tau Beta Pi.

WILLIAM DAVID GHERKY (A'95, M'96, F'13, member for life) president of the Railway Track-Work Company, Philadelphia, Pa., died January 17, 1937. Mr. Gherky was born January 7, 1868, at Portsmouth, Ohio. In 1886 and 1887 he was employed as a telegraph operator in railway and commercial service, and in 1888 was engaged by the Edison Electric Company and placed in charge of a 2,400-lamp plant and its associated underground system. At the end of that year he was transferred to the engineering department of the Edison United Manufacturing Company. He remained only briefly with the Edison companies, however, and after serving with the Field Engineering Company, New York, N. Y., accepted a position as engineer in charge of the underground system of the Philadelphia (Pa.) Traction Company in 1893. Later Mr. Gherky organized the Railway Track-Work Company and in 1917 formed the General Grinding Wheel Corporation, of which he was chairman of the board. He was a member of the American Association for the Advancement of Science.

JOHN WILBERT PURCELL (A'13) assistant engineer, Hydro-Electric Power Commission of Ontario, Toronto, died December 12, 1936. Mr. Purcell was born February 29, 1872, at Listowel, Ont., Canada. In 1890 he entered the electrical industry and worked in various manufacturing plants until 1893, when he became superintendent and chief inspector of the Detroit Electric Light and Power Company. He remained in that position until the company was sold in 1896. At that time he entered the employ of Hiram Walker and Sons, Walkerville, Ont., as superintendent of the light and power department. Mr. Purcell joined the staff of the Hydro-Electric Commission in 1912 as assistant engineer in the municipal engineering department, where his duties consisted of developing loads in urban municipalities and rural districts, and in the search for applications of electricity to agricultural uses. He was a member of the Association of Professional Engineers of Ontario, and formerly was an active member of the Canadian Electrical Association.

FREMONT WILSON (A'88, M'88, F'12, member for life) retired consulting engineer, Albany, N. Y., died October 27, 1936, according to word just received at Institute headquarters. Mr. Wilson was born July 15, 1861, at New York, N. Y., and attended the College of the City of New York. In 1882 he was employed by the Western Union Telegraph Company, but in the following year became associated with the Kuth Electric Company. From 1884 to 1887 he was engaged by the Edison Electric Company, New York, in the development of electric illuminating equipment, and from 1887 until 1892 he was with the Sprague Electric Company. Mr. Wilson established his own consulting engineering offices in New York in 1892, continuing as consultant to many electrical manufacturers until his retirement in 1934. He was particularly interested in the safety features of electrical devices, and was for many years consulting electrical engineer to the New York City Bureau of Fire Underwriters.

JOHN CLEMENT DOLPH (A'03, member for life) president and founder of the John C. Dolph Company, Newark, N. J., died February 5, 1937. Mr. Dolph was born September 28, 1864, at North East, Pa. He entered the electrical industry by accepting employment as an apprentice electrician with the Short Electric Railway Company, Cleveland, Ohio; later, he established his own business as a sales representative in electrical and street railway supplies, in New York, N. Y. In 1898 Mr. Dolph became manager of the insulating varnish department of the Sterling Varnish Company Pittsburgh, Pa., and in 1901 accepted a similar position with the Standard Varnish Company, New York. In 1910 he moved to Newark and established his own insulating varnish company under the name of the John C. Dolph Company. He was considered an authority on insulating varnish.

# Membership

## Recommended for Transfer

The board of examiners, at its meeting on February 17, 1937, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

**To Grade of Fellow**

Curry, Walter A., assistant professor of electrical engineering, Columbia University, New York, N. Y.
Mapes, Leland R., chief engineer, Illinois Bell Telephone Company, Chicago, Ill.

2 to Grade of Fellow

**To Grade of Member**

Judson, W. G., electrical engineer, Ward Leonard Electric Company, Mount Vernon, N. Y.
Rathbun, H. V., transmission engineer, Kansas City Power and Light Company, Kansas City, Mo.
Reznicek, Josef, professor of electrical engineering, Technical University, Prague, Czechoslovakia.
Starr, F. M., central station engineering department, General Electric Company, Schenectady, N. Y.
Summerfield, S. C., assistant engineer, New Jersey Bell Telephone Company, Newark.
Trost, F. J., assistant division distribution engineer, Public Service Electric and Gas Company, Jersey City, N. J.

6 to Grade of Member

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the national secretary before March 31, 1937 or May 31, 1937, if the applicant resides outside of the United States or Canada.

Abbott, L. J., Texas Power and Light Co., Decatur, Texas.
Aicher, L. C., Jr., Allis-Chalmers Manufacturing Company, Milwaukee, Wis.
Ambrosio, B. F., 335 Linwood Street, Brooklyn, N. Y.
Anderson, R. E., Lonoke, Ark.
Angelopoulos, N. C., Engineers, United States Army, Fort DuPont, Del.
Askren, L.eR., Frigidaire Corporation, Dayton, Ohio.
Bailey, C. W., Schlumberger Well Surveying Corporation, Tyler, Texas.
Barken, J., Powell and Power Engineers, Dallas, Texas.
Barbaro, A., 17 Batavia Place, Harrison, N. Y.
Barnard, R. B. (Member), U.S. Engineer's, 523 Pittock Building, Portland, Ore.
Barnes, D. P., Southern Utah Power Company, Cedar City, Utah.
Barr, J. M., Jr., 1515 Blanding Street, Columbia, S. C.
Bastedo, E. H., Anaconda Wire and Cable Company, Hastings-on-Hudson, N. Y.
Beahm, E. M., Albuquerque Gas and Electric Company, Albuquerque, New Mexico.
Beamer, S., Fireman's Fund Idemnity Company, San Francisco, Calif.
Beasley, R. R., Denver and Rio Grande Western Railroad Company, Murray, Utah.
Belding, M. D., Westinghouse Electric & Manufacturing Company, Knoxville, Tenn.
Bellows, G., Jr., General Electric Company, Schenectady, N. Y.
Betzer, R. W., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.
Beveridge, A. B., General Electric Company, Schenectady, N. Y.
Bixler, C. H., Allis-Chalmers Manufacturing Company, Pittsburgh, Pa.
Black, K. H., United States Army, Fort Lawton, Seattle, Wash.
Blake, W. J., American Rolling Mills, Middletown, Ohio.

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute record. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Eiler, E. E., 101 Brookline Court, Upper Darby, Pa.
Godoy, Ernesto R., Cia. Tel. y Tel. Mex., 16 de Septiembri No. 13, Mexico, D. F., Mex.
Hale, Edward E., Public Service Commission of New York, 80 Centre St., New York, N. Y.
Jones, Harry Kenneth, 5511 Kenmore Ave., Chicago, Ill.
Little, Leroy C., 3414—17th St., N., Cherrydale, Va.
Miyota, Nath S., 916½ Howell St., Seattle, Wash.
Moore, Everett, 821 Sunset Blvd., Los Angeles, Calif.
Peach, Paul S., Upperville, Va.
Pollastro, John B., Helper, Utah.
Sawyer, Fred E., 811 E. Wisconsin Ave., Milwaukee, Wis.
Wickel, F. A., Pier 42, Dollar S. S. Lines, San Francisco, Calif.
Wong, Harry Y. L., 771 Broadway, West New York, N. J.

**12 Addressed Wanted**

# Engineering Literature

## New Books in the Societies Library

Among the new books received at the Engineering Societies Library, New York, recently, are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface of the book in question.

CONGRÈS INTERNATIONAL des APPLICATIONS ELECTROCALORIFIQUES et ELECTROCHIMIQUES, Schéveningue, June 1936. Recueil des Travaux et Compte-Rendu des Séances. Publié sous la direction de l'institution Néerlandaise des Applications Electrocalorifiques et Electrochimiques, Secrétariat: Arnhem, Nachtegaalspad 1, Pays-Bas. Moorman's Periodieke Pers N.V., La Haye, September, 1936. 336 p., illus., diagrs., charts, tables, 10x6 in., cloth, 6 guilders. Includes papers on industrial electric heating, electric furnaces, and the heat treatment of metals. Some papers are in English, the remainder in French or German.

CONNECTING INDUCTION MOTORS. By A. M. Dudley. 3 ed. N. Y. and Lond., McGraw-Hill Book Company, 1936. 464 p., illustrated, 9x6 in., cloth $3.50. A practical guide to connection and repair of induction motors and in solving questions of making changes to meet varying conditions of voltage, current, and phase.

ELEKTRISCHE MASCHINEN. Volume 4. Die Induktionsmaschinen. By R. Richter. Berlin, Julius Springer, 1936. 440 p., illustrated, 9x6 in., cloth, 30 rm. Discusses the theory and design of single-phase and polyphase generators, motors, and voltage regulators. A-C commutator machines are omitted for consideration in a later volume. Useful to the advanced student.

MACRAE'S BLUE BOOK with which has been incorporated Hendrick's Commercial Register 44 ed. 1936/1937. Chicago, MacRae's Blue Book Company, 3,372 p., 11x8 in., cloth, $15.00 An annual directory following established lines. Includes lists of manufacturers of all industrial products, trade names, and trade facilities. Provides information on the makers of any product.

MATERIALPRÜFUNG mit RÖNTGENSTRAHLEN unter besonderer Berücksichtigung der Röntgenmetallkunde. By R. Glocker. 2 ed. Berlin, Julius Springer, 1936. 386 p., illustrated, 9x6 in., cloth, 33 rm. A practical text on the application of X rays to the study of metals. Discusses the production of X-rays, their properties and application. Emphasis is placed on practical methods of procedure.

MERCURY ARCS. By. F. J. Teago and J. F. Gill. Lond., Methuen and Company, 1936. 104 p., illustrated, 7x4 in., cloth, 3s. A brief outline of the more important electrical, mechanical, and operational features of the mercury arc. Adapted to those who wish a compact statement of modern views.

EIN NEUES ELEKTRISCHES SPRECH GERÄT ZUR NACHBILDUNG der MENSCHLICHEN VOKALE. (Einzelausgabe aus den Abhandlungen der Preussischen Akademie der Wissenschaften Jahrgang 1936. Phys.-Math. Klasse. Nr. 2). By K. W. Wagner. Berlin, Verlag der Akademie der Wissenschaften in Kommission bei Walter de Gruyter & Co., 1936. 44 p., illustrated, 11x6 in., paper, 3 rm. Describes a new electrical instrument for studying and reproducing the vowel sounds of the human voice, and gives the results obtained by the author.

SOUND EQUIPMENT, MOTION PICTURE PROJECTION, PUBLIC ADDRESS SYSTEMS. By J. R. Cameron. Woodmont, Conn., Cameron Publishing Company, 1936. 326 p., illustrated, 8x5 in., cloth, $5.00. Affords a course of instruction in the projection of sound pictures; the construction and operation of equipment is described in detail.

VALUE THEORY and BUSINESS CYCLES. By H. L. McCracken. 2 ed. N. Y. and Lond., McGraw-Hill Book Company, 1936. 259 p., charts, 9x6 in., cloth, $4.00. Designed to bring out the vital and fundamental relationship between value theory and business cycles.

VIBRATION and SOUND. By P. M. Morse. N. Y. and Lond., McGraw-Hill Book Company, 1936. 351 p., 9x6 in., cloth, $4.00. Intended primarily for students of physics and communication engineering, and is based on courses given at the Massachusetts Institute of Technology. Aims to give a general introduction to the theory of vibration and sound.

WIRELESS ENGINEERING. By L. S. Palmer. N. Y. and Lond., Longmans, Green, and Co., 1936. 544 p., illustrated, 9x6 in., cloth, $7.50. A revised and enlarged edition of "Wireless Principles and Practice." Provides information on all branches of radiotelegraphy and radiotelephony, in which theory and practice are combined. Suited to graduate students and practicing engineers in need of a reference book. Contains material on ultrashort-wave radio, beam-antenna systems, propagation through the ionosphere, and quartz oscillators.

APPLIED RADIOCHEMISTRY. (George Fisher Baker Nonresident Lectureship in Chemistry at Cornell University.) By O. Hahn. Ithaca, N. Y., Cornell University Press, 1936. 278 p., illustrated, 9x6 in., cloth, $250. Discusses the utilization of radioactive atoms as representatives of chemical elements in various lines of chemical research. Based upon lectures given at Cornell University in 1933.

SURVEY of the PRESENT ORGANIZATION of STANDARDIZATION; NATIONAL and INTERNATIONAL, published by the Central Office of the World Power Conference, Lond., W.C.2, 36 Kingsway, 1936. 55 p., tables, 11x7 in., paper 3s. 6d. (Gift of American National Committee, Interior Bldg., Washington, D. C.) Presents the facts regarding the national organization of standardization in 33 countries, and of 2 international bodies.

ASTM STANDARDS on ELECTRICAL INSULATING MATERIALS, prepared by Committee *D-9*, Specifications, Methods of Testing. September 1936. Philadelphia, Pa., American Society for Testing Materials, 1936. 329 p., illustrated, 9x6 in., paper, $2.00 ($1.50 to members). Includes the 1936 report of the committee on electric insulating materials with the proposed revisions of standards.

ÉLECTRICITÉ (Agenda Dunod) by L.-D. Fourcault. 56 ed. 392 p. Paris, Dunod, 1937. illustrated, 6x4 in., cloth, 20 frs. Contains numerical and other data frequently wanted by electrical engineers. Small enough for the pocket.

## Engineering Societies Library

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a co-operative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

Les COMMUNICATIONS RADIO-ÉLECTRIQUES, part 2. By H. de Bellescize. Paris, Gauthier-Villars, 1936. 218 p., illus., 10x7 in., paper, 30 frs. (parts 1 and 2, 50 frs.). Discusses fundamental problems of radio communication, such as the elimination of interference and the increasing of certainty of communication.

ACCOUNTING PRINCIPLES for ENGINEERS. By C. Reitell and C. Van Sickel. 2 ed. N. Y. and Lond., McGraw-Hill Book Company, 1936. 518 p., 9x6 in., cloth, $4.00. Sets forth the elementary principles of accounting upon which accurate cost findings are based, including accounting technique, basic principles of valuation, factory controls, revenue accounts, and the outline of advanced cost finding. Based upon a course given at the University of Pittsburgh.

Book of ASTM STANDARDS issued triennially. 1936. 2 volumes. Philadelphia, Pa., American Society for Testing Materials. Illustrated, 9x6 in., lea., part 1, 898 p., $7.50; part 2, 1477 p., $7.50 (2 parts, $14.) Contains standard specifications, test methods, recommended practices, and definitions formally adopted by the society. One part covers metallic materials; the other, nonmetallic materials.

ATM—Archiv für Technisches Messen. Lieferungen 63–66, September–December 1936. Munich and Berlin, R. Oldenbourg. Illustrated, 12x8 in., paper, 1.50 rm. Devoted to brief accounts of new developments in apparatus and methods for technical measurements.

AMERICAN ELECTRICIANS' HANDBOOK. By T. Croft. 4th edition revised by C. C. Carr. New York and London, McGraw-Hill Book Company, 1936. 1051 pages, illustrated, 7x4 in., leather, $4.00. A handbook for wiremen, contractors, linemen, and plant superintendents.

ANALYSES of BUSINESS CYCLES. By A. B. Adams. New York and London, McGraw-Hill Book Company, 1936. 292 pages, illustrated, 9x6 in., cloth, $3.00. Discusses the causes of business fluctuations and suggests reforms in business practices that would tend to eliminate extreme cycles.

CONNECTING and TESTING DIRECT-CURRENT MACHINES. By F. A. Annett and A. C. Roe. 2nd edition. New York and London, McGraw-Hill Book Company, 1937. 302 pages, illustrated, 9x6 in., cloth, $3.00. Gives practical instructions for the reconnection of d-c machines for a change in voltage or speed, or both, and also for locating and remedying faults.

ELECTRIC ARC WELDING PRACTICE. By H. L. Lewenz. London, Crosby Lockwood and Son, 1936. 126 pages, illustrated, 9x6 in., cloth, 8s. 6d. Describes the principles and practice of arc welding; intended to assist those who have actually to carry out the work.

ELECTRICITY. By W. L. Bragg. New York, Macmillan Company, 1936. 272 pages, illustrated, 9x6 in., cloth, $4.00. Presents the substance of the series of lectures delivered at the Royal Institution in 1934. Deals with the behavior of electrical charges, electrical circuits and magnets, and with such fundamental apparatus as cells and motors. Describes in detail the electrical apparatus in use in everyday life; written for the layman.

ELEKTROMOTOR und ARBEITSMASCHINE. (Schriftenreihe Ingenieurforthildung, Heft 1.) By F. Moeller and O. Repp. Berlin, J. Springer, 1936. 157 pages, illustrated, 9x6 in., paper, 4.80 rm. A practical textbook on electric motors and their use for driving machinery.

# Industrial Notes

**Large Motor Standardization.**—Electrical drives even for large power requirements have been developed to the extent that they are rapidly becoming standardized. For example, Westinghouse has built thirty-two identical steel mill motors rated at 1250 hp, 600 volts, 300–600 rpm. Installed in 4 different steel manufacturers' plants, each is used for driving cold strip or sheet mills.

**New Roebling Branch Manager.**—Arthur E. Gaynor has been appointed manager of the New York branch of John A. Roebling's Sons Co., succeeding William P. Bowman, who died on January 22.

**Cutler-Hammer Appointment.**—T. D. Montgomery was recently appointed by Cutler-Hammer, Inc., Milwaukee, as manager of the foreign sales division.

**Emerson Electric Appointment.**—The Emerson Electric Mfg. Co., St. Louis, has announced the appointment of Eugene P. Farris as manager of specialty sales, succeeding H. L. Parker, Jr., resigned.

**Lincoln Electric Appointments.**—The Lincoln Electric Co., Cleveland, Ohio, announces the appointment of B. J. Brugge, who spent 2 years superintending welding operations in the Near East, to the sales staff of its Los Angeles office. W. R. Smith has likewise been appointed to its sales staff. Robert A. Wilson, George Mandula, and A. T. Cox, Jr. have been appointed to the staff of the Chicago office.

**Pole Mounted Capacitors.**—A new type of weather-proof, steel clad, hermetically sealed 15 kva capacitor unit, suitable for pole mounting on distribution circuits, is announced by Westinghouse Electric & Mfg. Co., East Pittsburgh. These units contain an internal discharge device and are provided with means of mounting on brackets to crossarms or direct to poles, or in groups of four on single angle iron racks, making possible inexpensive installations up to 180 kilovoltamperes on one pair of crossarms.

**Marshall Electric Company Sold.**—The Ideal Commutator Dresser Co., Sycamore, Ill., announces the acquisition of the Marshall Electric Co. of Elkhart, Ind., manufacturers of automatic regulators for voltage, current and speed control of electrical equipment. The operations of the acquired company will be transferred as rapidly as possible to Sycamore and consolidated with the engineering, research and other departments of the purchaser.

**Westinghouse Office to Move.**—The Westinghouse Electric & Mfg. Co. will move its Pittsburgh office and some of its general offices now located at East Pittsburgh, to the Union National Bank Building in Pittsburgh about May 1. Occupying nine floors of the building, from the fifth to the thirteenth floors, the Pittsburgh district office, subsidiary district offices and headquarters offices including executive, legal, industrial relations, sales and accounting departments, will be centrally located in the Union Bank Building to facilitate their operations. Formerly the company's district office and subsidiary offices had been in this same building.

# Trade Literature

**Light-Sensitive Cell.**—Bulletin GEA-2467, 16 pp. Describes G-E light-sensitive cell, including complete technical and descriptive data. General Electric Co., Schenectady, N. Y.

**Beryllium Copper Alloys.**—Folder, 8 pp. Describes the properties of these heat-treatable copper alloys; lists electrical applications, among others, where it may be used to advantage. Beryllium Corp. of Pennsylvania, Reading, Pa.

**Transformers.**—Bulletin GEA-2442A, 8 pp. Describes unit-type distribution transformers; each unit completely self-contained, incorporating lightning and overload protection, overload indication, etc. General Electric Co., Schenectady, N. Y.

**Transformers.**—Catalog 105, 16 pp. Describes and illustrates the various phases of distribution transformer manufacture, showing cut-away models and including tables of voltage ratings, accessories, and price lists. R. E. Uptegraff Manufacturing Co., 316 No. Lexington Ave., Pittsburgh, Pa.

**Capacitors.**—Bulletin GEA-2494, 20 pp. Describes pole type distribution capacitors; a detailed presentation of power factor correction in distribution circuits and the applications and advantages of this type of equipment. General Electric Co., Schenectady, N. Y.

**Group Operated Switches.**—Bulletin 50, Cat. Sec. No. 1, 4 pp. Describes high-voltage, group operated switches, 88,000-S to 200,000 volts. This type is a rotating insulator, vertical break switch for outdoor substation and transmission line service. Pacific Electric Mfg. Corp., 5815 Third St., San Francisco, Calif.

**Outdoor Bus Supports.**—Descriptive Data 36-220, 16 pp. Includes specifications for apparatus insulators for standard and heavy duty service, bus supports for various types of mountings, and clamps for outdoor channel buses. Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

**Switchboards.** Bulletin GEA-2253A, 12 pp., "Modern Switchboard Styling." Largely a photographic treatment of the subject, illustrating the better appearance made possible by semiflush instrument mounting and available with control panels, metal-clad gear, cubicles, etc. General Electric Co., Schenectady, N. Y.

**Transformers.**—Bulletin 1186, 12 pp. Describes Type "SB" outage free distribution transformers. Discusses principles of operation, how transient surges are diverted, and the methods used to provide protection, as well as construction details of the transformers and protective equipment. Allis-Chalmers Mfg. Co., Milwaukee, Wis.

**Control Engineering Service.**—Booklet, 8 pp. Describes an engineering service for adapting leading manufacturers' apparatus to control problems of all kinds in every industry, and combining consultation, manufacturing, contracting, supervision and guaranteed results wherever a control problem arises to be solved. General Control Co., Cambridge, Mass.

**Motor Bearings.**—Bulletin EM-7, 40 pp. Describes and illustrates over 200 electric motor bearings. Alphabetical, progressive, and numerical size listings include bearings for any type motor. Sections are incorporated on bronze cored and solid bars, hexagon bars, lead-base and tin-base babbitt and general purpose phosphor bronze bearings. Johnson Bronze Co., New Castle, Pa.

**Tachometer.** Bulletin 705, 2 pp. Describes a new, normal rate hand tachometer, represented as about the most accurate device made for speed measurements The instrument has a scale graduated into 40 divisions. On the 1000 rpm range, this means that the instrument is arranged for 5 rpm per division and is quite easy to read to one fifth of a division or 1 rpm in 1000. Herman H. Sticht & Co., 27 Park Pl., New York City.

**Power-Factor Correction.**—Reference table for calculating necessary capacitor kva to correct load to desired power-factor. The chart among other functions computes the reactive kva required to raise the power-factor to any desired percentage. The reverse side of the chart shows the amount of current drawn by capacitors and also specifies the sizes of switches to be used with varying sizes of capacitors. Cornell-Dubilier Corp., South Plainfied, N. J.

**Micromax Recorder.**—Die-out ND(1), 8 pp. A novel advertising piece demonstrating the Silver-Anniversary Micromax Recorder. Cut to the actual shape of the recorder, the door of the case opens and swings out the chart carriage and whole mechanism into view, just as may be done with the actual instrument. Inside and out each unit is in true perspective, with chart and record in color. Though its range is that of a typical temperature recorder, the model demonstrates equally well the automatic indicating and recording of any of a wide variety of process conditions—not only temperature, but chemical concentration, pH, per cent $CO_2$, smoke density, liquid level, speed, frequency, load, voltage, etc. Leeds & Northrup Co., 4962 Stenton Ave., Philadelphia, Pa.

Entered as second class matter at the Post Office, Easton, Pa., April 20, 1932, under the Act of Congress March 3, 1879. Accepted for mailing at special postage rates provided for in Section 1103, Act of October 3, 1917, authorized on August 3, 1918. ¶ Publication Office: 20th & Northampton Streets, Easton, Pa. Editorial and Advertising Offices at the headquarters of the Institute, 33 West 39th Street, New York

**An inspection trip to the $375,000,000 Grand Coulee project on the Columbia River, about 92 miles from Spokane, Wash., is being included on the program of the Institute's 1937 Pacific Coast convention to be held in that city, August 30–September 3. It is planned also to include one or more papers dealing with the engineering features of the project. At the left is reproduced a photograph taken March 8 especially for ELECTRICAL ENGINEERING by the U.S. Bureau of Reclamation, showing the status of construction on that date. In the foreground is the completed foundation for one end of the dam which will rise to a maximum height of 550 feet and will contain 11,250,000 cubic yards of masonry. The entire project includes construction of a dam, a 2,700,000-horsepower power plant, and a pumping station on the Columbia River; a reservoir in Grand Coulee; main irrigation canals; and water distribution system on the project lands.**

# High Lights

**Engineering Education.** "American engineering colleges have a great responsibility in meeting the demands of the times so that their graduates will be capable as engineers and will also have . . . well-rounded ethical standards and broad interests. . ." So says a recognized authority in outlining current practices and trends in engineering education (*pages 414–17*). Careful consideration should be given to that phase of engineering education, and professional development, which follows the award of the bachelor's degree, according to another well-known educator (*pages 418–19*). Graduate courses for engineers are now being offered on a part-time basis by several educational institutions in Chicago, Ill. (*pages 417–18*). In order that the engineer may learn to write and speak with facility, it is suggested that the study of English should commence as soon as the student enters college and continue until he graduates (*pages 419–20*).

**Alternator Regulator.** A simple electronic voltage regulator for alternators, utilizing 2 mercury-vapor control tubes combined with a small inductance, capacitance, and resistance has been developed. Its sensitivity and operating speed are said to be comparable with those existing electronic regulators of more complicated design (*pages 462–4*).

**Economics and Business Courses.** To stimulate the interest of student engineers in economic problems, a brief but fairly comprehensive course in industrial economics and business methods is advocated in place of some of the highly specialized technical courses now included in engineering-college curricula (*pages 446–54*).

**End-Winding Inductance.** Formulas for calculating the end-winding self-inductance and leakage inductance of a salient-pole synchronous machine are given in a paper in this issue. An effort has been made to indicate the nature and consequences of the assumptions involved (*pages 355–61*).

**Magnetic Fluxmeter.** To provide means for continuous measurements of somewhat varying magnetic flux in air gaps, a fluxmeter employing 2 bismuth resistance elements (the resistance of which changes with changes in the flux) has been developed (*pages 441–5*).

**Ground Faults on Power Systems.** An extensive survey of faults to ground on representative power systems in different parts of the United States is recorded in this issue. (*pages 421–8*). Data on fault resistance obtained in this survey also are given (*pages 428–33*).

**Automatic Oscillograph.** Analysis of system disturbances alone may not justify the use of an automatic oscillograph, but this instrument may also be used to locate faults on transmission circuits, and for testing relays controlled by carrier current (*pages 438–40*).

**Oxidation in Insulating Oil.** A series of studies of accelerated oxidation in a highly refined paper-cable insulating oil is reported in this issue, with particular reference to the correlation between oxidation and electrical properties (*pages 465–74*).

**Electricity on Aircraft.** The use of electricity on aircraft has increased to such an extent that the wiring diagrams of modern planes are beginning to resemble those for electric power generating stations (*pages 406–10*).

**Voltage Drop.** Connection of load to only 2 phases in open star in a delta-star distribution network may sometimes be necessary; voltage regulation requires that the load be divided correctly, which may not mean equally, on the 2 phases (*pages 434–7*).

**Elihu Thomson Dead.** One of the last of the original group of great electrical pioneers, Elihu Thomson died March 13, 1937. He was a charter member of the AIEE and its fifth president (*pages 482–8*).

**District Meeting at Buffalo.** An interesting program of varied attractions has been planned for the North Eastern District meeting of the AIEE to be held in Buffalo, N. Y., May 5–7, 1937 (*pages 489–91*).

**Summer Convention.** Tentative plans for the Institute's 1937 summer convention to be held in Milwaukee, Wis., June 21–25, include 10 technical sessions and 1 general session (*page 491*).

**Auditory Perspective.** Reproduction of orchestral music in auditory perspective has been demonstrated out-of-doors with the orchestra present (*pages 412–13*).

**Prizes for Papers.** Rules for the award of Institute prizes for technical papers have been revised (*page 492*).

## DISCUSSIONS

Appearing in this issue are discussions of the following papers:

A-C Characteristics of Dielectrics—II—Banos . . 477

Dielectric Strength of Transformer Insulation—Bellaschi & Teague . . . . . 479

Statements and opinions given in articles and papers appearing in ELECTRICAL ENGINEERING are the expressions of contributors, for which the Institute assumes no responsibility. Correspondence is invited on all controversial matters. ¶ Subscriptions—$12 per year to United States, Mexico, Cuba, Porto Rico, Hawaii, Philippine Islands, Central and South America, Haiti, Spain, Spanish Colonies; $13 to Canada; $14 elsewhere. Single copy $1.50. ¶ Address changes must be received by the fifteenth of the month to be effective with the succeeding issue. Copies undelivered because of incorrect address cannot be replaced without charge. ¶ ELECTRICAL ENGINEERING is indexed annually by the Institute, weekly and monthly by *Engineering Index*, and monthly by *Industrial Arts Index*; abstracted monthly by *Science Abstracts* (London). ¶ Copyright 1937 by the American Institute of Electrical Engineers. # The President on Membership

AT least once each year, the president should discuss with the members the subject of membership; for without members there could be no organization, and our fundamental purposes would be impossible of accomplishment. The major accomplishment of the Institute results from the voluntary service so willingly rendered by the national and District officers and committees, the Section's officers and committees, and the authors of the technical papers—a service much greater than, and in addition to, their financial support. However, a great work cannot be accomplished without expense, and funds are necessary to meet these expenses.

The booklet "Membership" by Everett S. Lee, chairman of the finance committee and past-chairman of the Section and membership committees, gives a clear picture as to the advantages of Institute membership, the funds provided by the members, and how they are wisely expended to "advance the theory and practice of electrical engineering and the allied arts and sciences, and to maintain a high professional standing among the members." It is quite unnecessary for me to endeavor to add to this picture.

A society is exactly what its members are, and I shall never be satisfied until every qualified and interested electrical engineer in America is a member of the Institute. The larger the number of qualified engineers who support the organization by their membership, the greater is the prestige of the society and the wider is the opportunity for service to the profession through an intelligent direction of the personnel and use of the funds which they provide.

I have carefully considered the motives which actuate an electrical engineer in applying for membership, and it seems to me that they can be classified in 2 groups.

A. SELFISH INTEREST

1. A desire to be one of a distinguished group.
2. An interest in our technical activities.
3. A desire to advance his professional standing.
4. A desire to broaden his ability through presentation of his ideas and discussion of the ideas of others.
5. The seeking of an opportunity for acquaintance and fellowship with others in their profession.

B. UNSELFISH INTEREST

1. A desire to advance the prestige and standing of his profession.
2. The wish to support an organization offering to the younger engineers, with whom he is associated, opportunities for development and advancement in technical knowledge.
3. The desire to be associated with and participate in the activities of a society devoted to service to the profession.

The membership may possibly be grouped in the following classes:

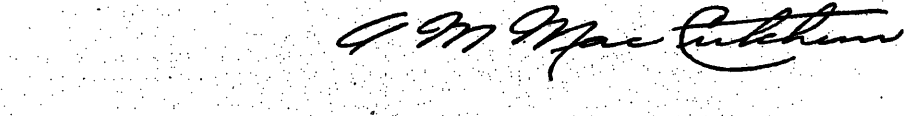
Class 1—*Sustaining.* Those, who in addition to their financial support, largely participate in organization activity, technical activity, student activity, and Section activity.

Class 2—*Participating.* Those who give financial support and attend the meetings and conventions.

Class 3—*Silent.* Those who render financial support and are interested, but do not participate.

Class 4—*Indifferent.* Those who give only financial support.

Class 5—*Dissatisfied.* Those, who through lack of information, lack of participation, or lack of consideration, feel that the organization is not effectively carrying out its purposes.



The first group is the most valuable, for in this group are the most interested members who consider membership in the AIEE a real privilege. It is the constant aim of the officers to transfer those in groups 3, 4, and 5 into groups 1 and 2; but the greatest factor in this desirable transfer is the member himself. Those who contribute most and participate most largely are invariably the most interested. From a very active member I have seldom heard any complaint as to the dues he pays, although he may logically suggest how his dues can better be expended.

Membership is one of our most important activities. It is not the purpose of the membership committee to argue or cajole an engineer into applying for membership; rather to inform him as to our purposes and aims, and draw to his attention the privilege and duty that is his if he is qualified.

I feel that the membership committee should give particular attention to the electrical engineers connected with companies using, but not manufacturing, electrical equipment, and in this they should be aided by the technical program committee. The fundamental purposes of the Institute would be greatly furthered by an increased membership in this group.

Would any engineer desire to see the activities of the professional societies discontinued? Does he wish others to carry on the work of which he should be a part, or does he wish to do his share? If, due to circumstances, he cannot be in class 1, how much greater is his obligation to be at least in class 3. If he feels that the society's activities should be modified, should he not join and within the organization lead the way to higher accomplishments?

The most powerful force toward increased prestige and increased opportunity for service through increased membership, is the attitude and co-operation of those who are now members. Each individual member should do his part. As expressed at the recent winter convention, our aim for 1937 should be to advise every qualified electrical engineer as to our aims and purposes, and invite his assistance in reaching our objective.

# Electricity Aloft

By S. PAUL JOHNSTON

**Apart from the more obvious uses of electrical devices for aircraft communication and navigation, electricity is playing an increasingly important rôle on board modern airliners.**

THE PROBLEM of electricity on aircraft has changed materially over the past 15 years. From a necessary evil whose sole function was to ignite explosive charges in engine cylinders, its use has become a question of first-rate importance in the design and operation of the modern airplane.

In 1918, embryo pilots in the Army Air Service used to sit up nights over the "complications" of the electrical circuits on the old Curtiss "Jennies" then in use. The "complications" consisted of a single magneto, 8 spark plugs, a simple "on" and "off" switch on the dash, and about 25 or 30 feet of wire.

By contrast, a modern military bomber, by no means a large airplane as ships go today, takes some 1,200 feet of wire to connect its various circuits. The large transport illustrated at the head of this article, which is known as the Douglas type *DC*-3 plane, and which is now in active production requires between 5,000 and 6,000 feet. Estimates for next year's 40-passenger machines show wiring requirements of over 18,000 feet per ship! The wiring diagrams are beginning to resemble the hookup for a central station or an automatic telephone exchange.

It would take many pages to examine in detail all the steps that lie between the old wartime planes and the modern passenger transport, electrically speaking. However, a few of the high spots might be touched upon to show that, although there are many special problems, basically the matter of the design and installation of the electrical equipment is not so different from the sort of thing with which, as a group, electrical engineers are already familiar.

Probably one of the earliest of the electrical problems on aircraft was the addition of the radio. But a detailed discussion of radio for communication and navigation is beyond the scope of this article. It may be pointed out in passing that beginning with the very simple wartime receiver and rudimentary transmitter, the equipment has been developed to the point where the new transports soon to be in operation will carry no less than 8 or 9 different radio sets of one kind or another, possibly including apparatus for facsimile reception and transmission and for "absolute" altitude determination. Each such installation costs many thousands of dollars, and adds several hundred pounds of weight to the airplane. Also, the power requirements of the radio are constantly increasing. Today the average transmitter has an input of 50 watts. Tomorrow it probably will be considerably greater.

## Lighting

Toward the end of the World War night flying began, and from early postwar mail days has been developed to the point where now flying is done at night as casually as in the daytime. This brought with it a number of lighting problems, apart from the question of lighting airports and airways—an important subject to electrical engineers, but also outside the bounds of the present discussion. Earliest solution to the emergency night landing problem was the carrying of a couple of open magnesium flares attached to the wing tips. This soon proved unsatisfactory, as well as dangerous, and the electric landing light came into being. Clearly, too, some form of navigation lights was necessary. Today, every commercial airplane must be

Essentially full text of an address presented before the transportation group of the AIEE New York Section on January 14, 1937.

equipped with powerful headlights for landing and also the familiar red, green, and white running lights.

Instrument-board lighting became of first-rate importance. The boards themselves have become immeasurably more complicated. Pilots must be able to see each instrument quickly and clearly. All sorts of direct and indirect lighting arrangements have been tried, including a development involving ultraviolet radiation. One airline has been studying the development of the argon light which projects an invisible ultraviolet ray. This ray is directed at radium-painted instrument dials and produces a brilliant glow. In total darkness the "black light" cannot be seen except for the effect it has on the radium dial faces. But even the best so far discovered still leaves something to be desired. A further complication arises from the fact that the intensity of the illumination must be varied at will by the pilot in order that the intensity of light in the cockpit will always match that outside so that his eyes do not have to adjust themselves when shifting from distant objects to the instruments and back again.

The lighting of passenger cabins is a special problem. Not only must general illumination be provided, but also individual reading lights, on separate circuits, must be installed at every seat, or in every berth. Toilets and washrooms, galleys, coat closets, mail pits, and baggage compartments must all have adequate lighting with separate controls. Warning lights in the pilot's cockpit indicate that all passenger and cargo compartment doors are properly closed and secured.

## Miscellaneous Devices

The dictates of passenger comfort have made necessary the provision of devices unthought of 15 years ago, as the accompanying pictures show. The galleys on the new ships will be provided with electric ranges for cooking—hot plates and grills. Coffee percolators and electric refrigerators also will appear. The latest washrooms are providing electric razors for the convenience of male passengers. Possibly air conditioning is in the offing.

United Air Lines

**Interior of "Skylounge" Mainliner**

Other electrical devices have already appeared and will continue to take on new forms as ships become larger. For years there has been complete call-buzzer service from passenger seats and from the cockpit to summon steward service. It was only one short step beyond that to a complete telephone system to all parts of the ship, a convenience that has already put in an appearance. The illuminated sign to warn of an approaching landing and to suggest the use of seat belts is commonplace. Then, since pilots are human and might sometimes forget to extend the retracted landing gear before settling down on a field, automatic warning devices that light red targets on instrument boards, or sound a warning horn behind the pilots' heads, or both, are now installed as regular equipment. All these are electrically operated and further complicate the maze of wiring on the modern airplane.

## Engine Equipment

The electrical problems connected with the engines themselves have become tremendously complicated. Ignition is still from magneto, but a much more powerful and dependable machine than those fitted on the old Curtiss *OX*-5 engines of 15 years ago. But where the wartime engines generally had only one, each modern aircraft engine has a complete dual system—2 magnetos, 2 complete sets of wiring, and 2 spark plugs per cylinder. There has been some discussion recently over the advisability of having 3 complete units per engine. Apart from duplication, the ignition has been further complicated electrically because of the presence of radio on aircraft. It is obvious that an ignition system but a few feet away from a highly sensitive radio receiver will cause trouble unless the former is electrically shielded. Complete metallic enclosure for every inch of ignition circuits is the only possible solution. This is not as simple as it may sound, and has been a source of no end of trouble that has not yet been completely overcome.

Even after many years of development, the spark plug is still a source of trouble and annoyance. The modern trend toward taking all possible power out of engine cylinders at high altitudes has opened new mechanical and electrical problems with plugs that were not thought of several years ago. New plugs are now coming into the market, however, that promise relief from present difficulties.

Starting engines 15 years ago was simply a matter of brawn. It was no problem (except to get clear without being hit on the head by the propeller) to "swing" a 90-horsepower engine. Starting a 1,000-horsepower motor is quite a different thing. Inertia starters energized by an electric motor, or direct-cranking electric starters are to be found on most ships today. The bigger the engines become, the larger the starters, and the greater the power required to operate them. All this is bad enough when

only one engine is involved. Most ships today have 2 engines. Tomorrow they will have 4—day after tomorrow, 6 or 8. Furthermore, the old single engine was in the nose of the ship. Multiple engines are commonly mounted along the wings where control for starters must be remote, connections complicated.

Because of the remote location of engines there are a number of other operations that can best be done electrically. Obvious is the measurement of temperatures at various parts of the engines by remote-reading thermocouples. Electrical gauges have been devised to show the level of fuel in tanks. Electric tachometers measure engine speeds in cockpits so far away from engines that mechanical drives would be too heavy and impractical. Engines may be accurately synchronized electrically, by matching up the phases of small alternators directly driven by each power plant. Lubricating oil in remote tanks may be warmed to operating temperatures before starting by immersion heaters permanently fitted. Certain instruments are kept free from accumulations of ice and snow by small electric heaters.

One of the latest electrical applications is the continuous indication of fuel-air mixtures in engine carburetors by analysis of the composition of exhaust gases in the exhaust manifold. The Cambridge Aero Mixture Indicator (now installed as regular equipment by most of the major airlines) operates on the thermal conductivity principle incorporating a Wheatstone bridge. The electrical characteristics of one leg of the bridge change with changes in the thermal conductivity of the surrounding exhaust gases, which, in turn, becomes a measure of the quantity of carbon dioxide in the gas. The latter, in turn, is a function of the fuel-air mixture supplied to the carburetor.

Every ship today where performance is an element is fitted with controllable-pitch propellers. The most common type is the hydraulic control developed by Hamilton-Standard of Hartford, Conn. Coming onto the market now, however, is a new electrically driven type introduced by Curtiss-Wright. Changes in blade pitch are made by a small electric motor mounted in the propeller hub and connected to the blades through gears with a very high reduction ratio. Power is supplied to the motor through a pair of slip rings and brushes. An automatic electrical governor has just been developed for this propeller so that it turns at constant speed regardless of power developed at the shaft.

## Retracting Units

There are a number of other electrical applications that have been developed through what may be called aerodynamic or operational considerations. For high speed and maximum efficiency an airplane must be "clean," that is, nothing must be permitted to project into the air stream that can possibly be withdrawn inside the smooth contours of the machine when in flight. This accounts for the present practice of retracting the landing wheels, wing tip floats (on flying boats), landing lights, certain radio antennas, and other projections while in the air. Today the field is divided between hydraulic and electrical mechanisms to accomplish these retractions, but, as the size of airplanes increases (and the trend is all in that direction) electric drives will probably predominate. Even if the actual operating elements are hydraulic, the pumps supplying the liquid under pressure will undoubtedly be electrically driven.

Ships that are "clean" require some sort of "air brake" to slow them down to a reasonable speed for safe landings. The brakes usually take the form of a flap under the trailing edge of the wing that may be pulled down at a sharp angle to the air stream. Such flaps, on large planes, are either hydraulically or electrically operated; but, as with the wheel retraction, as size increases, the electrical drive will probably predominate.

"De-icers" are a part of the winter equipment of modern commercial aircraft operating in northern countries. It is out of place here to describe their action, but sufficient to say that certain necessary control valves and air compressors are electrically driven.

The future holds other probabilities. As airplanes become very large—and indications are that the limit where these changes will have to be made is now approaching—it will be impossible for a pilot, unaided, to operate the flying controls. Some form of relay-operated servomechanism will have to be developed to move the control surfaces at the will of the pilot, just as a steering engine functions in a large steamship. Again, both hydraulic and electrical mechanisms are possibilities, but the probabilities favor the electrical. No ship has yet been built incorporating these ideas, but studies have already been made looking toward the future.

Also, as ships get larger, other power auxiliaries will be needed. Hoists will be needed for lifting cargo, for engine changing, for operating gang planks, for weighing anchors, and for a host of other things not yet thought of. For all such, the logical drive will be electrical.

## Power-Supply Problem

Doubtless the question has already occurred as to where the power is to come from to operate these many electrical devices. To date, the standard source of power on aircraft has been the ordinary storage battery—not exactly "ordinary," however, for the requirements of minimum weight, compactness, and high output have forced the development of special batteries. The average battery for transport planes today is $14^1/_2$ inches long, $7^1/_4$ inches wide, and $11^1/_4$ inches deep. It can supply about 88 ampere-hours at 12 volts and weighs about 70 pounds. One company has recently placed on the market a new battery having the same over-all dimensions and said to be capable of supplying 105 ampere-hours. Over-all dimensions are important because all modern transports have been built with a battery compartment of a standard size, and fundamental changes in design would be necessary to accommodate larger sizes.

Generators, driven directly by the airplane's engines, supply a certain amount of recharging to batteries in flight, but the demands are usually so high that the drain on the battery exceeds the replacement, and it is common

practice to remove batteries from every airplane at the end of every run and send them to the charging room. One of the last servicing operations before departure from a terminal station is to install a fresh battery in the plane.

It is good practice, also, in order to relieve the plane's battery of the heavy drains occasioned from starting engines to provide independent starting power on the ground. This may take the form of mechanical power applied from an outside mechanism (electrically driven, to be sure) or from providing starting batteries on small portable carts that may be connected into the plane's electrical circuits by means of cables and a plug in the body of the ship.

Electrical equipment, however, has been added faster than battery design could keep up. Even for present requirements, one battery is hard pressed to do the job. As soon as it becomes necessary to think in terms of 2 or 3 batteries on each plane, it becomes worth while to examine other possibilities to see if something else may not be found to yield the required power for the same weight carried. One answer is already in sight. It seems not unlikely that the large plane of the future will carry its own independently operated electrical power plant—a gasoline-driven motor-generator set delivering 110-volt alternating current.

Equipment already has been designed, and shortly will be commercially available in the form of small 4-cylinder air-cooled gasoline engines, to deliver at least 15 or 20 horsepower at altitudes up to 20,000 feet to drive a-c generators and other auxiliaries. These will be completely self-contained, will be installed in some convenient out-of-the-way place in the airplane (probably in one or more of the engine nacelles), and will be remotely controlled. Besides driving the generators they will also operate a number of auxiliaries now mounted on the main engines, thus improving over-all reliability by removing from the airplane's power plants a number of sources of potential failure. In addition, the exhaust heat from the small engines will furnish ample heat for maintaining proper temperatures in passenger cabins at high altitudes.

United Air Lines

**Pilots' cockpits are becoming increasingly complicated and present difficult lighting problems. This is on a Douglas DC-3 plane**

Another important feature is that such independent units may be kept in operation when the airplane is standing on the ground. Power is required in increasing quantities for use on board during stops, and it is obviously more economical—and safer—to keep the small plant running than to attempt to keep one of the main engines turning over to drive generators.

One of the first questions that came up in the consideration of independent a-c power plants was the matter of frequency. There would have been some advantages as far as operations on the ground were concerned in selecting 60 cycles. It would thus have been possible to plug into the circuits at the average field when standing in stations or in hangars. Weight considerations, however, ruled out 60 cycles. Familiar, of course, are the effects of higher frequencies in reducing the weight of iron in motors and transformers, so that the preference at the present time for equipment operating at 800 cycles is immediately clear. Some study has been given to intermediate frequencies, but the trend seems definitely toward the 800 level.

Once the break has been made away from the present 12-volt battery-operated system with its limitations, it is difficult

to predict how far electrically operated auxiliaries on aircraft may go. Once a really adequate source of electric power is assured in the form of an independent motor-generator set, designers may really begin to explore the possibilities of the field. They doubtless will find many new uses for electricity on airplanes that no one has yet dared to think about.

## Some Special Problems

So far, many points of similarity between the electrical problems on aircraft and the problems with which most electrical engineers are familiar have been considered. In closing, a few of the problems that are distinctly special because of the peculiar conditions under which aircraft operate may be mentioned.

First, and always foremost, is the question of weight. In other fields of transportation, weight control is a secondary consideration. In aircraft design it is all important. All additions to the tare weight of any airplane are immediately reflected in reduced range or in loss of pay load. The gross weight of an airplane for any desired level of safety or performance is fixed. Clearly, then, increases in the weight of the ship's structure or auxiliary equipment must come out of the fuel supply or out of the cargo. Each electrical unit, then, becomes a separate and distinct design problem, and must be treated as such. The separate load requirements must be calculated accurately and provided for without margins beyond those dictated by good sense for safe operation. For example, it will not do to install a $^3/_4$-horsepower motor simply because it happens to be on hand, when the job, with all allowances, requires $^5/_8$ horsepower. The difference in weight may seem negligible in each case, but the cumulative effect may run into many pounds. It is thus impossible to stock a few items to use over a wide range of requirements as is common industrial practice. Each item must be looked upon as distinctly special.

Likewise, mountings cannot be multiplied by 2 or by 3 just to be safe. Here, especially is weight control important. All fittings connecting electrical appliances to the main structure must be calculated down to the last ounce consistent with safe operation.

The selection of operating speeds for electrical equipment is dictated by weight considerations. In general industrial work, speeds are selected that will best fit certain desired operations. In aircraft, the highest practical operating speeds are selected to save weight. For example, an inertia-type engine starter turning at speeds up to 3,600 rpm may require a 20-pound flywheel to do a certain job. If the speed is increased to 12,000 rpm a wheel weighing between 2 and 3 pounds will produce the same energy. The same general considerations are true for the design of many items.

Because of the inherent characteristics of airplane structures, all the equipment mounted on them is constantly exposed to vibration over a wide range of frequencies. The ruggedness of design demanded by this type of treatment is not conducive to weight-saving, but again, the corners must be cut as closely as possible consistent with satisfactory operation. It is obvious, too, that such conveniences as delicately balanced relays and automatic switches cannot be used, although they often would be very helpful.

Another difficulty arises from the wide range of temperature to which aircraft is subject within a relatively short time. Thus an airplane may take off from sea level under moisture-saturated tropical conditions, and 25 or 30 minutes later be flying at some subzero condition at an altitude of 15,000 feet. Not only the temperature drop but the condensation may cause plenty of trouble in the electrical apparatus.

Then the wiring of all the electrical equipment is a problem in itself. Fifteen years ago, going back to wartime planes, a bit of open wiring on cleats did the job. Not so today. Everything must be run in metal conduit. All wiring and conduit must be mechanically strong to withstand the vibration. It must be electrically good to avoid possible fire hazard and to provide adequate radio shielding. In many places positive-action quick-detachable connecting plugs must be provided to permit quick replacement of certain units such as engines, whole radio sets, or individual instruments.

Space has not permitted more than a hasty review of the several problems of the electrical equipment on modern aircraft, but it is hoped that they have been demonstrated to be of vital importance to the development of our latest transportation industry, and that they are worthy of the attention of the best electrical talent in the country.

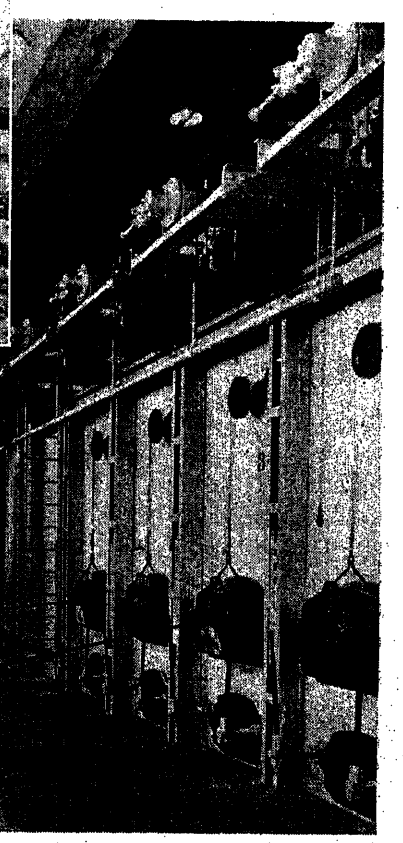
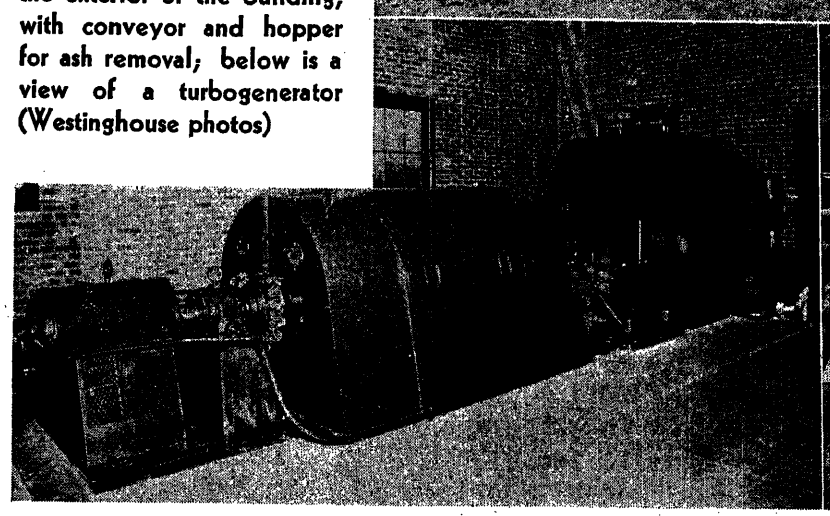
# Power From Waste Heat of an Incinerator





A new incinerator plant at Providence, R. I., uses the hot gases from a 5-cell incinerator with a normal capacity of 160 tons of refuse per 24 hours to generate steam in a 700-horsepower boiler at a pressure of 200 pounds per square inch. The steam is used in a 1,250-kw turbogenerator which furnishes power for operating the city's sewage disposal plant and will furnish power for a sewage pumping station now being motorized. A duplicate boiler and turbogenerator assure continuous service. The view above shows wrapped garbage and refuse being dumped into the 1,000-cubic-yard storage pit. At the right is shown the exterior of the building, with conveyor and hopper for ash removal; below is a view of a turbogenerator (Westinghouse photos)

(Above.) An electric crane with $1^1/_2$-cubic-yard bucket lifts refuse from storage pit to charging bin

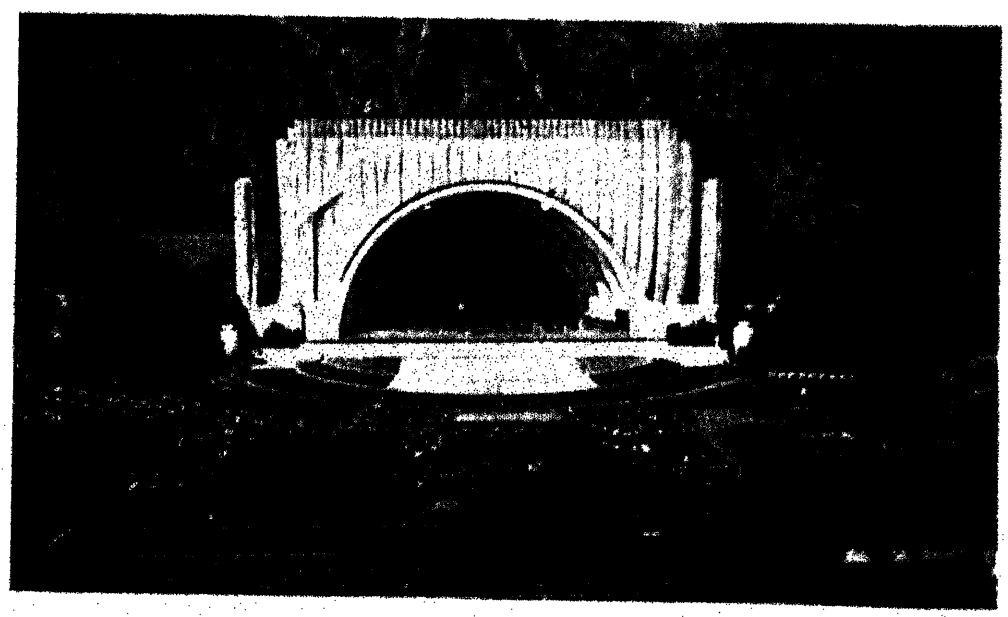
# Sound Reinforcing System for Hollywood Bowl

A NEW demonstration of the potentialities of the reproduction of orchestral music in auditory perspective was given at the Hollywood Bowl in California last August, when music reproduced in this manner was heard for the first time out-of-doors with the orchestra present. The occasion was a concert presented by Paramount Pictures with Leopold Stokowski acting as the conductor.

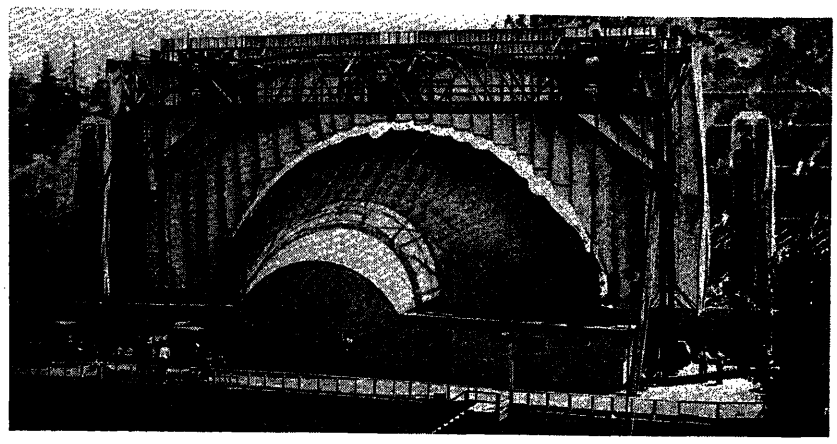


Reproduction in auditory perspective was first demonstrated in 1933. Music played in Philadelphia, Pa., was picked up by microphones, amplified, and transmitted over 3 special telephone circuits to Washington, D. C., where it was again amplified and reproduced by means of 3 huge loud-speakers. The equipment used in this original demonstration was described in a group of papers published in the January 1934 issue of ELECTRICAL ENGINEERING. The characteristics of this equipment were such that the entire frequency and volume range of the most exacting orchestral and vocal music could be reproduced without impairment of quality. The spatial arrangement of the microphones and the corresponding arrangement of loud-speakers was such as to provide substantially perfect auditory perspective. Both the original equipment, and that used in the Hollywood demonstration was developed by the Bell Telephone Laboratories, New York, N. Y.

The Hollywood Bowl is a natural amphitheater situated in a hollow surrounded by low hills. Oval in form with the stage at the lower end, its tiers of seats rise in curved rows up the sloping hillside at an inclination of about 12 degrees. It seats 22,500 persons. The orchestra plays in a large conical sound-reflecting shell on the stage. This shell raises the sound level effectively in the front and central portions of the seating area but not adequately in the side and back sections.

To correct these inequalities in sound distribution and to increase the general level of the music throughout the bowl a multichannel reproducing system was installed. This system also offered the additional advantages that (1) special effects could be obtained by changing the volume and sound quality with manual controls and (2) the loudness of the singers or solo instruments could be increased relative to that of the orchestra.

In providing such equipment for the bowl, conditions not previously encountered in indoor auditoriums had to be met. Since no walls or ceiling were present to reflect sound, arrangements had to be made to direct all the low as well as the high frequencies toward the audience. Moreover, since the loud speakers had to be placed near the orchestra to create the illusion that the sound all came from the orchestra, care had to be taken to prevent the sound from the loud speakers from feeding back into the microphones, which would cause singing. These and similar difficulties were overcome by using new equipment particularly designed for the demonstration.



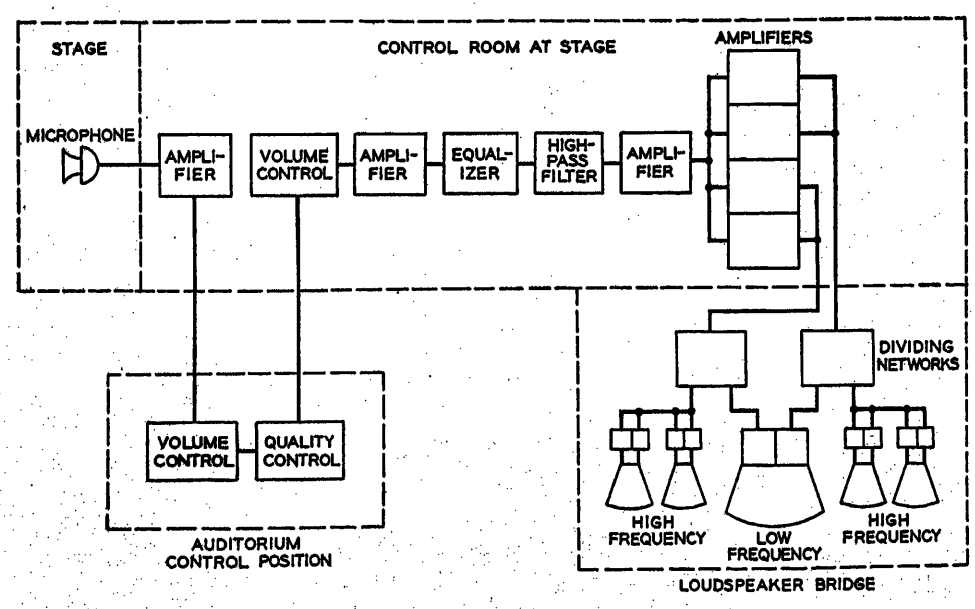
The general plan of the system as installed was to provide 3 microphone positions in front of the orchestra one at the left side, one in the center, and one at the right side. A separate amplifier channel of high power was provided for each of these positions and the output of each channel was connected to separate loud speakers mounted above the orchestra shell in positions corresponding to the microphones. Six microphones were used on the 3 channels. Two were connected in parallel on the left channel to give a satisfactory balance for the cellos, harps and bass viols, because the microphones had to be placed close to these instruments to avoid feedback. Two were located at the center so that one would be available to switch in instead of the regular microphone for vocal soloists. At the right, in addition to the regular microphone, there was an extra one out in front of the shell. This was used for harp and cello solo numbers instead of the regular microphone. The volume controls were located in the center of the seating area about 300 feet back from the shell, and at this position the gain of all 3 channels could be varied by one control. When the soloist's microphone

View of Hollywood Bowl after installation of loud-speakers

Includes essentially full text of an article by A. R. SOFFEL of the Bell Telephone Laboratories, Inc., New York, N. Y., published in the March 1937 issue of *Bell Laboratories Record*.

was switched to the center channel, however, a separate volume control was provided for it so that the level of the voice could be changed independently of that of the orchestra. Quality control made it possible to accentuate the low frequencies and temper the very high frequencies, and an equalizer compensated for the characteristics of the loud-speakers, microphones, and air-transmission path. The amplifiers were adjusted to keep the system below the "singing" point at all times. The acoustic power output of the side channels was 200 watts per channel and that of the center channel half that capacity.

**Rear of orchestra shell showing bridge structure erected to hold the $2^1/_2$ tons of loud-speakers**



The loud-speaker groups on the sides consisted of 4 multiple-unit high-frequency horns each driven by 2 receivers. These were mounted above 2 low-frequency units, like those used in the Philadelphia-Washington demonstration, which were placed one on top of the other with a common extension. This extension presented an area of 10 by 12 feet at the mouth which made the low-frequency units directive down to 50 cycles. The sound beam of the horns, both low- and high-frequency, was about 85 degrees wide and 50 degrees high. The center loud-speaker group comprised 2 high-frequency horns and only one low-frequency unit, which was built out to 10 by 10 feet in mouth area. The field current supply to each side group consisted of 3 power units, while 2 units supplied the current for the center group.

To mount these $2^1/_2$ tons of loud-speakers above the orchestra shell it was necessary to construct a bridge structure 112 feet long and 12 feet wide, 45 feet above the ground. The center speakers were directly above the center of the shell and the side speakers were each 45 feet from the center of the bridge. The bridge was artistically draped and lighted, which added not a little to the appearance of the shell. All amplifier and circuit equipment was mounted in a room at the stage.

After the system had been installed, acoustical measurements were made with a high-speed level recorder at various places over the seating area and the horizontal angle of the high-frequency horns was adjusted to direct more of the sound to the back seats than to those in front. This resulted in a fairly even distribution of sound; 10 decibels was about the greatest difference in sound level between any 2 positions. The maximum gain settings were found with no audience in the bowl. With an audience, however, 4 or 5 decibels more gain could be used without trouble from "singing."

In actual tests with the orchestra present an increase in sound power of 40 times (16 decibels) was obtained when the gain of the system was set at maximum. Although ordinarily this much amplification was neither used nor desirable, it was available to accentuate crescendos. Even in the first row of seats where the sound of the orchestra itself arrived a fraction of a second before that from the loud-speakers, the illusion that all the sound was coming from the performers was still strong. At the rear of the bowl, $^1/_{10}$ mile from the stage, the music level was at full volume; and for the first time vocal soloists could be heard satisfactorily.

This demonstration was a good illustration of how telephonic research can help to expand the horizon of music. The multichannel reproducing system described here gives to an orchestra a covering power previously unattainable and makes possible fortissimo effects that could not be duplicated by the simultaneous efforts of hundreds of musicians.

**A typical "stereophonic" channel, 3 like this were used in the Hollywood demonstration**

# Engineering and Engineering Education

By A. A. POTTER
President, American Engineering Council

**Because it is considered to be timely, informative, and lucid, this article is republished* here so that the many members of the Institute who are interested in, but not intimately associated with, the field of engineering education may have the benefit of a reflection of current practices and trends in engineering education as seen by a recognized authority in that field.**

ENGINEERING strives to provide better and easier ways of satisfying human needs. The astounding improvements which the past 50 years have brought about in our standards of living have gone on simultaneously with a more general appreciation of engineering education. This type of education, started in this country about 110 years ago, received its first impetus by the passage of the Morril Land-Grant Act of 1862, which provided means for the rapid extension of engineering education. From 1862 to 1934 the number of engineering colleges in this country has increased from 6 to over 150, and the engineering enrollment from about 1,000 to over 50,000. The rapid growth in the number and in the enrollment of the engineering colleges of this country during the past 70 years is an indication that there has been public approval of the type of education offered by these institutions. To an increasing extent industries, utilities, and public works are dependent upon engineering college graduates for the solution of their technological problems as well as those of an administrative and executive character. It is significant, for example, that nearly all of the major executives of electrical manufacturing industries and of electrical utilities are graduates of engineering colleges.

Engineering of a century ago was mainly an art. Thus, engineering colleges during the earlier years of their existence stressed manual dexterity; they were concerned more with training for the acquirement of skill than with education in basic principles; they placed major emphasis upon studies which led to usefulness immediately after graduation and not upon general educational values. Developments in transportation, mechanical power, communication, illumination, chemical technology, mining, metallurgy, manufactured gas, central heating, mechanical refrigeration, and other new industries and public utilities have resulted in a demand for special educational preparation. Engineering colleges attempted to meet these new requirements by setting up numerous specialized engineering curricula. In fact, there developed a tendency to magnify the differences between civil, electrical, mining, mechanical, and other branches of engineering. This has resulted in training specialists who are fairly well versed in one narrow branch of engineering but lack preparation in basic theory and an appreciation of the work of other engineers. Actually the work of the engineer in practice has not followed these branches of specialization set up by engineering colleges and the engineering societies, but has been organized largely along the functional lines of research, design, production, operation, and sales.

Meanwhile the underlying sciences have been growing complex as rapidly as have their applications to industry. Also, organized society has become diversified even more rapidly than either. Thus the gap between what the incoming freshman student knew and what the engineer in practice was expected to know became too broad to bridge in 4 years. During the past 30 years there has been a definite trend away from the purely utilitarian and specialized in engineering education. The engineering colleges have given up the idea of trying to train, in a 4-year undergraduate curriculum, specialists for the various fields of application. The best of these institutions have been tightening their entrance requirements, and have been concentrating upon subjects which are basic and which the student has difficulty in acquiring by his own efforts. While the scope and range of the engineering field has been constantly broadening, increased emphasis is now being placed by engineering teachers upon fundamentals. Completeness of details is being subordinated to thoroughness. The providing of a background of engineering knowledge is not being considered as important as development of ability to reason logically and to arrive at truth by observation and analysis. The time given to informational courses is being greatly reduced and an effort is being made to awaken the creative instinct of the student, and to stimulate independence of thought and self-reliance. Specialization is being definitely discouraged for undergraduates, but is given a place in connection with research in the graduate programs of study which lead to the higher degrees.

Contrary to the general impression, undergraduate engineering instruction is not purely technical, but has been planned so that the undergraduate student devotes about one-half of his time to science, mathematics, and the humanities. Nearly all engineering undergraduate curricula include required courses in English, history, and economics. In a number of engineering colleges the undergraduate program of study permits electives in psychology, sociology, accounting, personnel administration, businesss law, banking, corporation finance, and other courses which are helpful to the student in acquiring an under-

Doctor A. A. POTTER is dean of engineering, Purdue University, Lafayette, Ind.; also, president of the American Engineering Council, past-president of The American Society of Mechanical Engineers, and past-president of the Society for the Promotion of Engineering Education.

standing of social and economic problems. To an increasing extent, engineering students are receiving instruction in industrial engineering and management. It is the general opinion, however, that extended business training should not take the place, in an engineering curriculum, of basic instruction in science and technology.

The growth of junior colleges and of lower and upper divisions in universities has brought to the front the relative advantages of the unified program in which the scientific, technological, and humanitarian studies form an orderly whole in an engineering curriculum, as contrasted with the divided process having two years of a general college or pre-engineering curriculum and a subsequent purely technical curriculum corresponding to the practice of law, medicine, and dentistry. The conclusions of the exhaustive survey made under the direction of the Society for the Promotion of Engineering Education during 1922–1929 favor the 4-year unified engineering college undergraduate curriculum with unity of supervision rather than the divided program under separate administration.

While the soundness of the unified 4-year engineering undergraduate curriculum cannot be questioned, concentration on collegiate forms of education seems to have resulted in the neglect of other forms of technical education. There are no doubt too many institutions in this country offering engineering instruction of collegiate grade. Adequate training facilities for trades and crafts are also available. However, there is a need for specialized technical training which can best be given in a post-secondary type of school, recently designated as a "technical institute." This type of institution is similar to the technical middle schools of Continental Europe and trains for callings and functions between the skilled crafts and the scientific professions. Industry apparently needs for every engineering college graduate 3 people trained in this type of post-secondary school, where the instruction is more intensive and more specialized, and the program of study is shorter than that of colleges.

Until very recently, the interest of engineering colleges has centered in undergraduate instruction, as industry and the engineering profession have given inadequate recognition to resident graduate study. However, during the past decade graduate study or some other form of advanced study has become a necessity for the higher technological posts of industry. In several cases industries have perfected special arrangements with the educational institutions of their localities so that the engineering college graduate may complete requirements for higher degrees by pursuing advanced study while he is gaining industrial experience. Growth in graduate study has been particularly noticeable since 1930, as many of the unemployed have been striving to improve their education. Graduate study is now receiving definite encouragement at a number of engineering colleges as the preparation of their staffs has improved and as better research facilities have become available for the solution of new and advanced problems.

Doctor William E. Wickenden, in his final report as director of the survey of engineering education by the SPEE, made the following pertinent statement about post-scholastic study:

> The most serious deficiency in engineering education is not so much in matter taught or omitted in college, as in allowing the orderly process of education to stop, where it often does, at graduation. To require all engineering students to remain 5 or 6 years in college would be an arbitrary solution, but an artificially simple one.—It seems that the most urgent educational task now before the engineering profession is to create and direct an effective program of continuation education for the first 5 years after graduation from college.

The engineering profession has, in the past, taken little active interest in shaping or in directing engineering education. What aid has been given to engineering education by engineers has been largely individual and unofficial and has not represented the concentrated thought or the united action of the engineering profession. It is, therefore, gratifying that the recently formed Engineers' Council for Professional Development, representing as it does the leading engineering societies, has its program focused upon the educational preparation of the engineer. This council has set as one of its main objectives definite encouragement for the further personal and professional development of the college graduate as a qualifying standard for certification into the engineering profession.

In planning for the future of engineering education it may be desirable to give consideration to the following matters:

The undergraduate engineering college curriculum, concentrated on the underlying fundamentals, should become an accepted form of modern collegiate education, as it acquaints the student with the processes, devices, and methods which make our civilization distinctive. Cultured people are those who understand their environment—the world in which they live—and no type of education so directly assists the individual to understand his present surroundings as engineering education. Some of the graduates of engineering college should be encouraged to continue their preparation for engineering as a career, but a much larger number should be assisted in qualifying to enter the other professions, business and public service.

Considerable pressure is being brought to bear upon engineering colleges to increase emphasis upon business procedure and industrial management. Doctor R. E. Doherty, president of the Carnegie Institute of Technology, is of the opinion that in our enthusiasm to train leaders for industry we must not forget to provide an educational preparation and a promising outlook for technical engineering leadership. President Doherty's warning is timely. Technical engineering leadership and scientific positions must be made worthy and promising on their own score and not merely as a stepping stone for executive and administrative positions. Furthermore, the requirements for a successful executive are a broad range of knowledge and a disciplined mind to attack new problems. All that the engineering college can hope to do is to lay a foundation upon which the graduate may build in preparation for technical or executive responsibilities. Patrick Henry has well stated: "I know of no way to judge the future but by the past." It is only by giving our

students a broad foundation that we can properly prepare them to cope with the changing conditions of our times.

Greater attention must be given to economic and historic studies so that the engineer will have a better appreciation of the co-ordination of technology and economics as well as of the science of government which controls his affairs. During the past year several engineering colleges have announced special curricula as preparation for public service. The functions of government are becoming more and more technological in character, and to an increasing extent the engineer's activities are concerned with public works. It is therefore becoming more desirable that all engineers have a better appreciation of the relation of engineering to the public and to its agent—the government. All intelligent people must take an active interest in public questions, as only under a stable government can one make the best use of his talents.

It may be well to give greater attention to studies which will prove helpful in acquainting the student with industrial working conditions, tendencies in industrial organization and legislation, and other matters which may enable him to appreciate the human problems he will encounter. The engineer must know the human element if he is to utilize most effectively the work he designs or builds.

The engineer of tomorrow must have a thorough scientific preparation if he is to make full use of the foundations laid by science. Science and technology are interdependent, and the future progress of one depends upon the other. There is a trend toward more thorough instruction in science and mathematics, and for the general broadening of basic theory in engineering instruction. Quality rather than quantity is the guide in revising programs of study, as the superficial familiarity with many subjects is less valuable than the complete mastery of a few.

College graduates are found to have difficulty in recognizing and in appreciating true values. A better coordination of the educational and social activities of the undergraduate may prove helpful. More of the engineering undergraduate studies should be administered by socially minded professors. A more accurate appraisal of college student activities may also prove desirable. In a number of industries, art and beauty have recently changed deficits into profits. American industry has become aware of the remarkable potency of beauty. Art as a living thing will have to be appreciated by the engineer of the future.

Engineering colleges will do well to devote more attention to the development of desirable personality traits in their students, such as a good address, an agreeable manner, a cheerful attitude, a co-operative ability, a pleasing disposition, and similar traits which are helpful to the professional man in taking his place in society.

A most important objective of all education is the development, on the part of youth, of worthy ideals of character and conduct. The stability of society and the basis for authority in a democratic government depend upon the character and ethical standards of people. It is the duty of all types of schools, colleges, and universities to inculcate high ethical standards, and particularly during the adolescent period of youth when one is highly susceptible to the call of high purpose and refined ideals.

There is always a demand for people of initiative who have the power to think independently and constructively. We are living in an age which places a premium on initiative, the power to take the lead, to plan, to originate. To develop such traits, students must be encouraged to take new paths, to try new experiments, to look into the unknown. To develop the creative leaders of the future, our college students must have opportunities to come in contact with teachers who are in search of nature's truths. Engineering progress is dependent upon research, and new knowledge is absolutely essential for the advancement of engineering education. Furthermore, effective graduate instruction must be accompanied by active research interest on the part of the staff. Engineering is a profession of progress, and the future advances in applied as well as in pure science will depend upon coordinated and organized research. During recent years research problems of great magnitude have been successfully solved by engineering colleges as a result of cooperative relations with industry. Engineering societies, trade associations, industries (both large and small), and public utilities have found that money invested in research at carefully selected engineering colleges paid big dividends, not only in practical results secured but also in increasing the supply of engineers who have the preparation to extend the frontiers of useful knowledge. The best engineering colleges are not satisfied with teaching and the conservation of knowledge as their only function. They realize that efficient technological instruction must find expression in the application of research. Such institutions are always ready to encourage their staffs and their students to extend the boundaries of engineering and other scientific knowledge. American industry has an opportunity to aid in improving the preparation of engineers and scientists by stimulating research in pure and applied science at technological institutions. Such support will result in advancing basic knowledge in science and engineering, will increase the supply of well trained personnel for the research laboratories of industry, and will insure a greater number of people who have intellectual curiosity and ability to extend the frontiers of knowledge.

Engineering touches the life of every person in an industrial nation, so that the general well-being is vitally dependent upon the education of the engineer. From its origin and nature, the engineering college has in the past fallen short of the prime glory of the so-called classical or liberal arts college, which has been fairly successful in inculcating in the minds of its students a strong sense of personal responsibility to their order, their country, and their civilization. This may be partly responsible for the fact that engineers have been in the past too much concerned with the problems of their specialty, and have given little attention to the wider significance of their work or to their social responsibilities. Engineers are expected to think more, to write more, and to talk more on social, political, and economic problems in order to be able to assist in their solution. The engineer must assume the

responsibility of social leadership along with representatives of other major professions, in order to aid in stabilizing our national economy and to insure a truly democratic government.

American engineering colleges have a great responsibility in meeting the demands of the times so that their graduates will be capable as engineers and will also have the well-rounded ethical standards and broad interests valid in any professional group. The engineer of today must have a thorough preparation in science and technology, as well as an appreciation of aesthetic values, economic forces, and social trends. At the same time, he must be interested in government and must be conscious of the fact that the stability of our type of government depends upon citizens—citizens with worthy ideals of character and conduct; citizens who are obedient to law; citizens interested in the common good; citizens tolerant of the lawful rights of others; and citizens who realize the interdependence of human rights and property rights.

# Part-Time Courses for Graduate Engineers in Chicago

By H. T. HEALD
Member, The Society for the Promotion of Engineering Education

ENGINEERING educators are familiar with the development of graduate work in engineering during the past 15 years, and know that graduate registrations have greatly increased during this period. The increasing importance of graduate training suggests that in large metropolitan communities opportunities should be provided to enable young engineers to carry on a program of advanced study through part-time classes while regularly employed.

Beginning in 1935 the Western Society of Engineers in Chicago has directed the attention of its education committee to this phase of education. . . the assignment of making a study of the facilities for part-time graduate education for engineers and for developing a plan whereby the Society might encourage this type of work.

The study carried out by this committee disclosed that approximately 8,000 engineers between the ages of 22 and 34 were employed in the Chicago area, and that, while adequate provision for undergraduate training was available in evening classes, very few advanced courses were being offered by Chicago colleges, aside from a limited program begun at Armour Institute of Technology in the spring of 1936. Various engineering societies had from time to time sponsored lecture courses, some of which proved quite successful, but the committee felt that any comprehensive program should be carried out by the regularly established educational institutions. Consequently, the co-operation of the University of Illinois and the Chicago colleges and universities was invited, and a plan developed for a program of courses to begin in the fall of 1936, to be sponsored jointly by the Western Society of Engineers and the educational institutions.

As a result, graduate courses for engineers are now being offered on a part-time basis by the University of Illinois, Armour Institute of Technology, Lewis Institute, and the University of Chicago. Courses for the first semester included one class in continuous frames offered by Professor Hardy Cross, through the extension division of the University of Illinois, at the rooms of the Western Society of Engineers; 9 courses, including Diesel engineering, heat and ventilation, alternating current networks, foundations and soil mechanics, water treatment, fuels and combustion, metallurgical materials of construction, advanced calculus and physics of electron tubes, by Armour Institute of Technology; courses in non-ferrous metallurgy, metallurgical calculations, and differential equations by Lewis Institute; and electrodynamics and X-ray crystal analysis, as well as other advanced work in science, at the University College of the University of Chicago. Approximately 300 students enrolled in the combined group of courses in the fall of 1936, showing that a real demand exists for advanced work of this type.

While it is undoubtedly true that only a portion of the students enrolled are interested in working toward an advanced degree, credits obtained are recognized by the respective institutions, and the program at Armour Institute of Technology permits a properly qualified graduate to earn the master's degree upon the completion of a minimum of 8 courses. Arrangements for transfer of credits between institutions are subject to the regulations of the respective schools.

The Western Society of Engineers, functioning as a correlating agency, has made its library available to all students enrolled in these classes, irrespective of membership, and has issued announcements, covering the entire program, which have been mailed to 9,000 engineering graduates.

During the current year the education committee of

Republished, at the suggestion of the AIEE committee on education, from the March 1937 issue of *The Journal of Engineering Education*, published by The Society for the Promotion of Engineering Education.

H. T. HEALD is dean and professor of civil engineering at Armour Institute of Technology, Chicago, Ill.

the Western Society of Engineers, including both educators and engineers, is studying the effectiveness of the program already being offered, and attempting to determine the needs for additional work of this type. To assist in this study the committee plans to collect opinions from employers of engineers, as well as to take a census among a large number of engineering graduates, to determine the general fields of engineering in which there may be a demand for advanced study. This information will enable the colleges to relate their programs closely to the needs of engineers in the Chicago area, and should be of material assistance in planning courses for 1937–38.

Although the general program of graduate work for engineers employed in Chicago is still in a development stage, the response to the first year's work has been particularly encouraging. With proper development in succeeding years this type of work seems destined to become an important service to engineers who desire to secure additional professional training during the early years of their employment.

# After Graduation—What Then?

By H. P. HAMMOND
President, The Society for the Promotion of Engineering Education

A PRINCIPLE on which there seems to be universal agreement is that it is notthe aim of the undergraduate curriculum to produce "finished" engineers—men capable of engaging in responsible professional practice. It follows, therefore, since the profession is concerned in the eventual development of men capable of such practice, that consideration—very careful consideration—should be given to that phase of engineering education, and of professional development, which follows the stage marked by the award of the bachelor's degree. This seems so obvious as scarcely to need statement, yet it is a matter to which very little constructive effort has been devoted and to which, until now, none has been directed by the profession as a whole.

Some 4-year graduates will and should remain in college for more extended training. At present about one-sixth of those holding the bachelor's degree continue their work for a fifth year and secure the master's degree, and a smaller, but increasing, proportion go on to the doctorate. This is as it should be; the engineering college, while not the only place, is doubtless the best place, generally speaking, in which programs of advanced study and research can be conducted. For the bulk of our graduates, however, the formal part of their engineering education stops at the end of the 4 collegiate years, whether or not this is best is not the question now under consideration; even, however, if the program of collegiate engineering education were extended to 5 years, or to 6, the fundamental question of the post-scholastic engineering education and the professional development of the young engineer would remain, demanding consideration of those interested in the welfare of the profession.

What are the elements of this problem and how may it be approached? It may be worth while to summarize some of them even though they are already well and widely known.

There is, of course, the problem of fitting the man to the job, or the job to the man (happily there are now jobs to which men can be fitted). This phase of the problem is of concern to every administrative and personnel officer. Real progress has been made in connection with it in recent years. A committee of the Society [for the Promotion of Engineering Education] under the chairmanship of Professor Bangs, of Cornell, has as its particular duty continued study of this matter.

There is also the problem of giving the graduate—or the about-to-be graduated student—some comprehensive knowledge of the profession he is about to enter—of its professional organizations, of the opportunities it offers and the responsibilities it involves, and of its ideals and ethical standards. Some progress has been made in connection with this phase of the general problem, but apparently less than its importance deserves. Both the schools and the profession have a direct responsibility in relation to it.

Every graduate who plans to follow engineering practice as a career should affiliate himself with the appropriate national societies and local groups of engineers and thereby identify himself as a member of the profession he is joining. While this may be considered as chiefly the concern of the engineering societies, it is one toward which the engineering schools should feel a sense of responsibility.

Then there is the matter of the continuation of the education of the young engineer, and this is the chief problem to which these remarks are addressed. Heretofore our profession has done, or perhaps it might be fairer to say has been able to do, very little in this connection. In some urban centers an increasing number of graduates are

Republished at the suggestion of the AIEE committee on education, from the March 1937 issue of *The Journal of Engineering Education*, published by The Society for the Promotion of Engineering Education.

H. P. HAMMOND is professor of civil engineering at Brooklyn (N. Y.) Polytechnic Institute.

availing themselves of opportunities for post-graduate instruction offered in evening hours by colleges of the vicinity. In some industries, but almost exclusively in the largest, training programs are provided which range from regular study of a post-graduate nature to planned sequences of experience in various departments of the company. But on the whole there is little or nothing in our profession that serves the purpose of the period of systematic apprenticeship which the medical graduate experiences during his interneship. Up to the present time no means have been available of assisting or of guiding the graduate who feels the need systematically to continue his education through self-directed study. No greater need or opportunity exists for the engineering profession today than in this respect.

And finally there is the matter of informing the graduate of the requirements and procedures of the registration laws in the several states. The college and the profession jointly have an important responsibility in this connection.

Until the present time the various aspects of the induction of the graduate into his career and of his professional development and advancement have been dealt with only sporadically; the profession as a whole has not united in considering the matter or in providing means for dealing with it. The reason for this has been chiefly that no agency has existed through which a common program of effort could be undertaken. Now, happily, that lack no longer exists. The Engineers' Council for Professional Development, upon which the interest of the colleges has centered recently in connection with the accrediting program, has the broader purpose indicated by its title—*professional development.* Accrediting of schools, though a vital matter, is but one phase of the broader program which the council has undertaken. Matters relating to the personal and professional growth and development of the graduate as an engineer and a citizen are being dealt with by one of the council's committees, that on professional training. It was the inauguration of the program planned by this committee on which Past-President Rees [of SPEE] was actively engaged at the time of his death. O. W. Eshbach [chairman, AIEE committee on education] is now serving as the chairman of this committee, which is continuing the work along the same lines as those originally laid out. The work of this committee is of vital importance to the entire profession. It deserves to be supported and assisted . . . as need and opportunity arise.

# English in Engineering Education

By C. W. DUNHAM
Port of New York Authority

A MAN is able to convey his thoughts to another person only as perfectly as his own means of expression and the other's understanding of it will permit. Most people in our country are limited to the use of just one tool for this purpose—the English language. How great a part it plays in our lives! How great, then, should be its development! Yet engineers are notoriously weak in their mastery of it.

In the past we have given much study to the determination of the best curricula for the undergraduate work of our engineering colleges in order to give our young engineers the best possible preparation for their life work. My own contacts with graduates for the past 16 years indicate that the results have been good as far as technical education is concerned. However, young engineers are generally deficient in their ability to express themselves with effectiveness and facility, whether orally or in writing. Those who are really capable in this respect are the exceptions rather than the rule. Yet, unfortunately, many of the impressions which create the "boss's" idea of a man's ability are secured through the latter's use of English. Therefore, it is tremendously important for a young man to be competent in handling this great means of conveying his thoughts and knowledge if he is successfully to hold a position of leadership among other men who are well trained in this respect. The question naturally arises, "What can be done about it when the time and capacity of the students are already strained to the limit?"

Obviously, it is unwise to keep piling course upon course in undergraduate curricula. This should not be necessary in order to attain the desired result. Day after day the students are steeped in the study of mathematics, sciences, and similar subjects, but all these studies are carried on through the medium of the English language. Why then, cannot the development of the use of this medium itself become a well-planned though almost unconscious part of all studies?

Naturally, in this connection, the desired goal is the development of the ability to use the ordinary written and spoken words of everyday life with facility, to write concisely and well, to think straight, and to speak clearly and effectively while on one's feet before people as well

Republished at the suggestion of the AIEE committee on education from the March 1937 issue of *The Journal of Engineering Education*, published by The Society for the Promotion of Engineering Education.

C. W. DUNHAM, assistant engineer, design division, Port of New York Authority, is a member of the American Society of Civil Engineers, and of The Society for the Promotion of Engineering Education.

as in the quiet of one's study. Not only the faculty members but the students themselves should realize the importance of these attainments.

To accomplish this goal the study of English should commence as soon as the student enters college and it should continue until he graduates. The faculty of the English department should teach the theory of writing and effective speaking, but the practice of its teachings should be carried out day after day in the other departments by having the closest kind of co-operation among them all. The English professors in a few hours each week should not be expected to counteract the effect of careless or bad habits formed elsewhere. These other departments should insist that all written examinations, reports, theses, and similar work of the students must be satisfactory in composition as well as in subject matter. Oral interrogations or recitations should be held in order to give valuable practice in quick thinking and extemporaneous speaking. These last will also give the students the incidental benefit of listening to the questions and answers of others.

Of course, such a program will require painstaking work on the part of the teachers. However, the possibilities for real service are too great to be neglected.

The classroom is not the only place where practice in the use of the English language should take place. Competition in public speaking, participation in the work of the college paper, preparation of essays and their presentation at meetings of the student branches of the engineering societies, discussion of such essays, prepared and extemporaneous debates, and similar activities should be a regular part of the college life.

I shall try to illustrate the need of this training and its benefits by giving a few examples from the experiences of engineers whom I know. All are true cases even though the names of the individuals are not disclosed.

A chief engineer wanted someone to study a certain bridge project and to make a report upon his findings. As it happened, the engineer who usually did such work for him was on his vacation, therefore, the problem was assigned to a younger man. The latter made the necessary investigation and estimate, then hastily compiled his report. He delivered it in person to the chief engineer. The latter read it in the presence of the assistant chief engineer and the author. He figuratively tore it to pieces because of its poor form and composition although he did not criticize the correctness of the figures. Obviously, that young engineer suffered much more than injury to his feelings.

In another instance a young designer was asked to help with some specification writing during an emergency. He soon demonstrated such clearness and exactness in writing that he was transferred to this part of the organization, receiving at the same time a substantial raise in salary and an advance in title. Some of his fellows failed to realize that the reason for his promotion was an accomplishment whose value they had overlooked.

The preparation of specifications is a good example of the need for exactness in writing. Repeatedly, trouble develops from their indefiniteness or misinterpretation of them. One case centered upon one short descriptive phrase of four words which the contractor claimed meant something entirely different from the intention of the author. The dispute was finally settled with a loss of about $75,000 to the owner.

In another instance a company wished to carry on a lecture program to advertise its engineering services. One of the concern's lawyers was assigned to the job. After the first attempt he was recalled because he did not have the technical background to answer the questions put to him. An engineer was then sent out to carry on the work. His knowledge was sufficient but his presentation of the subject was so uninteresting that he too was recalled immediately. The program finally had to be finished by a few of the men higher up in the company who took turns at the job. The effect of this affair upon the first 2 men needs no comment.

A different kind of case is that of a company which sent one of its engineers to confer with a customer about difficulties that had arisen between them. The engineer understood the matter well enough, but he could not discuss the details calmly and clearly. He soon became antagonistic in his attitude and failed miserably in his mission. The result was an oral order by the chief engineer stating that this man must never again be permitted to represent the company in such matters. His future progress was wrecked. One might say that this case represents poor character rather than weakness in the use of the English language. However, knowing the individual as I do, I believe that his failure was due largely to inexperience in debate and in controlling his speech under difficult circumstances.

Another case concerned 2 young engineers who were about equal in technical ability. The first seemed to be afraid to express himself and to present his views. When he attempted to do so he was inclined to be hesitant and unconvincing in his speech. The second was unafraid, forceful, yet tactful and clear in his discussions. The result was that the second young man steadily forged ahead of the other. Such things have happened too frequently to be commented upon further.

It seems to me that there are 2 sides to this matter of correct and effective use of English which one should master. The first is the attainment of a good vocabulary and knowledge of what is right and proper composition. The second is the development of courage and ability to get on one's feet, to say something worth while and to say it well. These can be mastered by the students only if they are given long-continued practice in writing and speaking in college until they become so accustomed to expressing themselves properly that eventually they are able to concentrate their minds upon their ideas rather than upon the search for words to express those ideas.

In conclusion, let me urge that proficiency in the use of the English language be given one of the chief places among the goals to be striven for by our engineering students. Let it be attained by the whole-hearted co-operation of the entire faculty of the colleges. Thus will our young engineers go forth to Life possessing one of the great qualifications for success.

# Power System Faults to Ground

## Part I: Characteristics

By C. L. GILKESON MEMBER AIEE  P. A. JEANNE MEMBER AIEE  J. C. DAVENPORT, JR. NONMEMBER AIEE

## Synopsis

THE RESULTS of an extensive oscillographic study of power-system faults to ground are presented herewith. While this study was made primarily to obtain data useful in inductive co-ordination problems, the results are believed to be of general interest as well. They provide data on such items as frequency of occurrence of ground-current disturbances, their monthly distribution, duration, cause, method of clearance, and wave-trace characteristics. Data on fault resistance are given in part II, a companion paper.

## Introduction

In connection with a study of low-frequency residuals and methods for their control, conducted by the Joint Subcommittee on Development and Research of the Edison Electric Institute and the Bell Telephone System with the co-operation of several power companies, numerous oscillographic records of power-system currents and voltages at times of disturbances producing ground current, together with information as to the cause and nature of the disturbances, were obtained. Records were secured from 10 systems which were under observation for periods ranging from approximately 1 to approximately 5 years. These records have been analyzed from various standpoints to provide information as to characteristics of power-system faults and disturbances which involved ground current. Since some disturbances were self-clearing and some were due to reclosures on sustained faults, switching, etc., a somewhat special meaning has been attached herein to the terms "disturbance" and "fault" to facilitate the analysis of the data, namely:

*Disturbance.* Each individual oscillographic record of abnormal 60-cycle current, irrespective of its cause or duration, represents a disturbance.

*Faults.* The number of faults was arrived at by eliminating from the total recorded disturbances those having a duration of one cycle or less, and those which the power-system trouble records or the oscillogram characteristics indicated to be recurrences of, or reclosures on the same case of trouble. The word "fault" is therefore used to distinguish the disturbances which were probably associated with initial dielectric failure from the total number of disturbances recorded. The requirement of more than one cycle duration for faults was arbitrarily chosen to eliminate from this classification brief surges, many of which were attributed to switching, paralleling of 2 systems, etc.

The data presented herein apply, with minor exceptions, solely to disturbances producing earth-return current and are not concerned with disturbances resulting from phase-to-phase or 3-phase faults except to the extent that these may develop into ground faults as well.

The information given in this paper may be roughly divided into 3 main classes, relating, respectively, to (1) the monthly and yearly frequency distribution of disturbances and faults, (2) classification of disturbances to determine their cause and nature, this classification being based on power-system trouble reports, and (3) certain characteristics of troubles, such as duration, manner of fault clearance, and number and sequence of phase wires involved, this information being deduced principally from the appearance of the oscillographic records.

## Source and Nature of Data

The power companies who participated in the collection of the data and whose co-operation made this study possible were the Appalachian Electric Power Company, Central Illinois Light Company, Central Illinois Public Service Company, Superpower Company of Illinois, Dayton Power and Light Company, Pennsylvania Power and Light Company, Philadelphia Electric Company, Potomac Edison Company, Public Service Electric and Gas Company, Tennessee Electric Power Company, Union Gas and Electric Company, and Wisconsin Public Service Corporation.

The power systems utilized in the study are all located in territory where, according to data of the United States Weather Bureau,[1] the average expectancy of thunderstorm days per year is from 30 to 60. They cover an operating voltage range from 26 to 220 kv; some of them operate with directly grounded neutral and others with neutral grounded through impedance. Certain relevant characteristics, such as system voltage, circuit mileage, method of grounding neutral, and extent and kind of ground wires utilized are listed in table I.

For recording disturbances, automatic oscillographs were used. They were tripped, in most cases, by residual or neutral current and were provided with means for photographing the time of occurrence of each disturbance. Provision was made for recording neutral, residual, or line currents in all cases and for recording positive- and negative-sequence and line-to-ground voltages in some cases. All oscillographic records were correlated as far as was practicable with power-system trouble records.

A paper recommended for publication by the AIEE committee on power transmission and distribution. Manuscript submitted January 5, 1937; released for publication February 24, 1937.

C. L. GILKESON is assistant engineer with the Edison Electric Institute, New York, N. Y.; P. A. JEANNE and J. C. DAVENPORT, JR., are engineers with the Bell Telephone Laboratories, Inc., New York, N. Y.

1. For all numbered references, see list at end of paper.

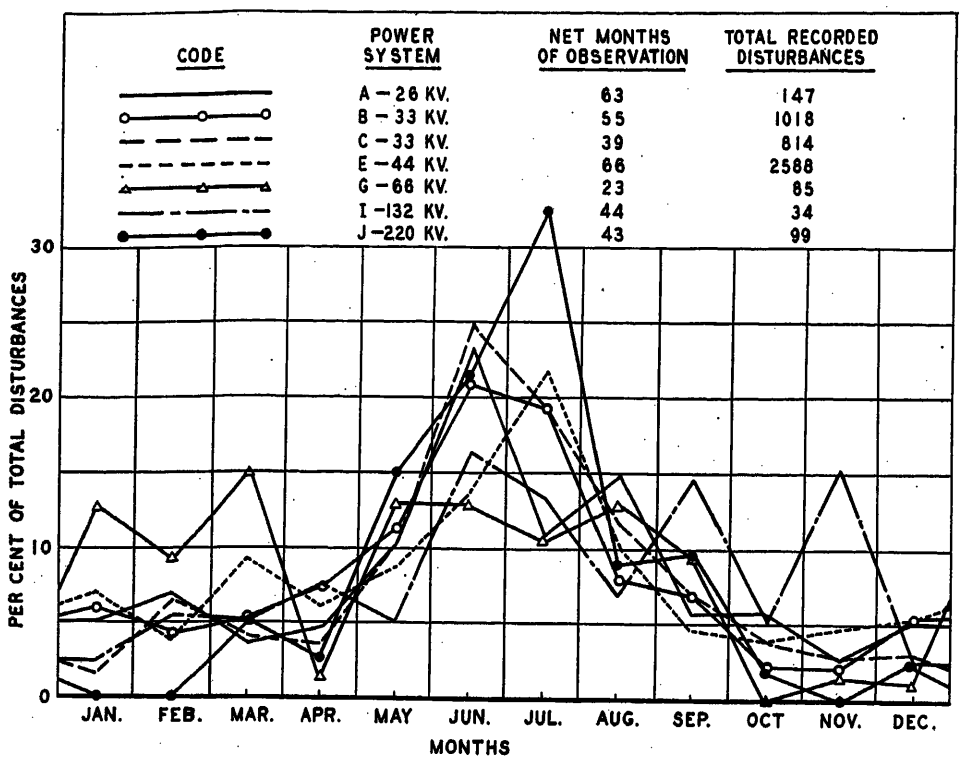

**Fig. 1. Monthly distribution of disturbances recorded during entire periods of observation; systems A to J, inclusive, 26 to 220 kv**

## Frequency Distribution of Disturbances and Faults

### Disturbances and Faults per Year per 100 Circuit Miles of Transmission Line

The yearly and, in most cases, the average yearly frequency of occurrence over several years, of disturbances and faults involving ground current are shown in table II for the various systems. This classification was made only for the 7 systems from which suitable data were obtained and only for the calendar years for which the data were practically complete.

The data indicate, in most instances, considerable variation from year to year. The most important cause of this variation is probably the varying severity of lightning storms in different years. This is well illustrated by the fact that weather reports for the city around which system *B* centers show that there were 51 days on which thunderstorms occurred in 1931, compared with 30 in 1930.

### Monthly Distribution

The monthly distribution of the disturbances recorded for the entire periods of observations on each of 7 systems are shown in figure 1. Systems *G* and *I* do not show as great a seasonal variation as the other systems, probably because these systems have more effective protection against lightning. System *J*, which operates at the highest voltage, shows a decided seasonal variation, due to the fact that a part of the line mileage is in hilly territory subject to severe electrical storms, and because, at the time of these observations, one section of line did not have effective ground-wire protection.

In figure 2 are shown 3 average curves of monthly distribution of disturbances. The 2 broken-line curves were prepared by averaging the percentages shown in figure 1 for the systems operating at voltages from 26 to 44 kv and 66 to 220 kv, respectively. The solid-line curve is a probability curve, based on the percentage data from all systems.

**Table I—Relevant Power-System Characteristics**

| Power System | Line Voltage Kv | Approximate Circuit Mileage: Wood Pole | Steel Tower | Cable | Total | Neutral Grounds: Number | Type | Ground Wires | Remarks |
|---|---|---|---|---|---|---|---|---|---|
| *A* | 26 | 140 | | 30 | 170 | 1 | 75-ohm resistor | None | Sequential observations on 2 similar networks |
| *B* | 33 | 275 | 125 | | 400 | 1 | 30-ohm resistor | Some low conductivity | *Equivalent zero-sequence impedance—540 ohms |
| *C* | 33 | 250 | | | 250 | 1<br>4 | Grounding bank*<br>Solid | Some low conductivity | |
| *D* | 37 | 64 | See remarks | | | | Solid | Some low conductivity | Only one 64-mile wood-pole line under observation |
| *E* | 44 | 193 | 342 | | 535 | 1 | 150-ohm resistor | See remarks | 72-mile high conductivity; remainder low conductivity or none |
| *F* | 44 | 215 | | | 215 | 2–4 | Solid | | Two grounds at first, others added later |
| *G* | 66 | 200 | 112 | 1 | 313 | 1 | 30- or 60-ohm resistor | Low conductivity | Switching arrangements permit resistance of 30 or 60 ohms |
| *H* | 120 | | | | 434 | | Solid | Low conductivity | Numerous neutral grounds on this system |
| *I* | 132 | | 167 | | 167 | 1 to 4 | Solid | High conductivity | Number of grounds gradually increased from 1 to 4 |
| *J* | 220 | | 354 | | 354 | 4 to 5 | Solid | High conductivity except one section for portion of period | System mileage changed from 234 to 354 |

## Correlation Results

Wherever practicable, the oscillograms obtained from each power system were correlated with power-system trouble records. In the case of system *E*, correlation was obtained for oscillograms of voltages induced in an inductively exposed telephone line as well as for the neutral-current records, thus increasing the amount of usable data from this system. The correlation provided information as to one or more of the following items: (1) whether or not a disturbance was noticed on the system at the time an oscillogram was obtained, (2) cause of disturbance, (3) number of phase wires involved, (4) how cleared, i.e., whether self- or circuit-breaker cleared, (5) location of disturbance (line involved and more definite location if known), (6) damage, if any, to the system, (7) any other pertinent information which was available.

In table III is given, where practicable, a classification of all correlated disturbances in accordance with the attributed primary cause of the disturbance and the nature of the trouble experienced on the power system. As mentioned earlier, only disturbances producing ground current, that is, one or 2 line-to-ground or unbalanced 3 phase-to-ground disturbances are included in these data. In order to show exactly what has been included in the various classifications, some of the items are explained in more detail at the end of the table.

In obtaining correlation between the oscillographic records and power-system troubles for system *E*, more attention was paid to the geographical location of the fault and the actual damage to the system than to the primary cause of the disturbance. For every other power system included in this report, the primary cause of the disturbance was given first consideration, but the correlation, especially with regard to lightning as the primary cause, is by no means considered perfect for any system. The correlation is probably the best for systems *A*, *I*, and *J*, but it is thought that the percentage of records directly attributed to lightning is, in all cases, especially system *E*, too small. It is probable that most of the disturbances in items *A*-2 and 3 of table III were also caused by lightning. Consequently the sums of the percentage values of items *A*-1, 2, and 3 of table III are probably more nearly representative of the percentages due to lightning than are values in item *A*-1 alone.

The values given in table III include all correlated disturbances, irrespective of their duration. While correlation of very short duration disturbances usually would not be expected, a number of those of one cycle or less duration were correlated as due to foreign objects in the line and failures at substations. It seems probable that these were mostly disturbances during the preliminary stages of dielectric failures, such as the spitting over of a transformer bushing just prior to breakdown. They were frequently closely followed by long-duration disturbances. For example, several consecutive oscillograms were sometimes obtained showing an occasional half-cycle or cycle of the type illustrated in the central portion of figure 5, followed by an oscillogram of uniform wave shape of the type shown at the bottom of figure 5. (This particular illustration is a reproduction of one

continuous oscillogram, and according to earlier definition, represents one disturbance.)

## Fault Characteristics Deduced From Oscillograms

### Durations of Disturbances and Faults

This portion of the analysis is intended to give, as nearly as possible, a representative picture of the distribution of disturbances and faults with respect to their durations while involving ground, as determined from oscillographic records of power-system neutral and residual currents. The results for each of 8 power systems are shown graphically by the cumulative percentage curves in figures 3 and 4. The differences between the curves in these 2 figures, for corresponding systems, are due largely to the elimination of disturbances of one cycle or less duration from the curves applying to faults.

Because of the multiple neutral grounding and system layouts, the durations for systems *F* and *H*, obtained by an oscillograph at only one location, were not necessarily the total durations of the troubles. For the other systems included in figures 3 and 4, total durations were shown by the oscillographic records.

### Wave-Trace Characteristics

The oscillograms of neutral or circuit-residual current from each of 9 power systems have been classified in accordance with the characteristics shown by their wave traces. Under this classification the oscillograms have been listed as those showing (1) uniform wave, (2) uniformly attenuated wave, and (3) irregular wave. Those having uniform wave traces presumably indicate constant resistance faults and the others variable resistance faults. The results of this study are shown in detail in table IV. Wherever oscillograms showed one cycle or less duration, or could not properly be included under any of the 3 classifications noted above, they have been placed under headings noting these facts.

Some typical oscillograms illustrating these characteristics are shown in figure 6. In many cases, the basis for this classification was not as clear-cut as might be inferred from these illustrations alone.

**Table IV—Wave-Trace Characteristics of Disturbances**

| Power System | Total Records Classified | Classification of Wave Trace, Per Cent: Uniform | Uniformly Attenuated | Irregular | One Cycle or Less Duration | Unable to Classify |
|---|---|---|---|---|---|---|
| *A* (26 kv) | 147 | 42.9 | 2.7 | 34.0 | 12.9 | 7.5 |
| *B* (33 kv) | 1,018 | 51.9 | 8.7 | 21.2 | 9.6 | 8.6 |
| *C* (33 kv) | 814 | 40.7 | 1.8 | 32.3 | 19.4 | 5.8 |
| *E* (44 kv) | 1,962 | 54.3 | 3.1 | 22.7 | 11.9 | 8.0 |
| *F* (44 kv) | 100 | 65.0 | 1.0 | 10.0 | 24.0 | 0 |
| *G* (66 kv) | 85 | 58.8 | 3.5 | 15.3 | 20.0 | 2.4 |
| *H* (120 kv) | 226 | 71.6 | 2.7 | 8.8 | 16.0 | 0.9 |
| *I* (132 kv) | 34 | 76.5 | 5.9 | 8.8 | 5.9 | 2.9 |
| *J* (220 kv) | 67 | 71.7 | 0 | 9.0 | 9.0 | 10.3 |

### Manner of Clearance

The determination of the manner in which a disturbance cleared, i.e., whether breaker-cleared, self-cleared, or involving some combination of these, was based on (1) correlation data and (2) appearance of the oscillogram wave trace. On this basis, the oscillographic records

| 3. Per cent—location unknown | 6.8 | 14.1 | 8.3 | 9.9 | 28.6 | 23.8 | 12.3 | 3.4 | 22.7 | 13.5 | 12.8 |
| **A. Classification as to primary cause** | Percentages of Net Disturbances—See Above | | | | | | | | | | |
| 1. Lightning | 39.7 | 47.6 | 57.7 | 41.7 | 27.4 | 33.3 | 52.2 | 31.1 | 60.9 | 42.9 | 48.1 |
| 2. Primary cause unknown | 38.4 | 18.6 | 19.8 | 21.0 | 1.2 | 0 | 4.6 | 24.1 | 8.2 | 19.8 | 12.3 |
| 3. Cause, location, and type of trouble unknown | 6.8 | 14.1 | 8.3 | 9.9 | 28.6 | 23.8 | 12.3 | 3.4 | 22.7 | 13.5 | 12.8 |
| Sum of above—probably due to lightning in most instances | 84.9 | 80.3 | 85.8 | 72.6 | 57.2 | 57.1 | 69.1 | 58.6 | 91.8 | 76.2 | 73.2 |
| 4. Wind, sleet, snow, rain, and flood—no lightning reported | 3.0 | 10.6 | 7.8 | 22.0 | 0 | 16.7 | 0 | 3.4 | 0.9 | 8.7 | 1.4 |
| 5. Foreign objects | 10.6 | 7.9 | 4.5 | 4.8 | 21.4 | 13.1 | 4.6 | 27.6 | 0.9 | 9.8 | 11.0 |
| 6. Switching | 1.5 | 1.2 | 1.9 | 0.6 | 21.4 | 13.1 | 26.3 | 10.4 | 6.4 | 5.3 | 14.4 |
| **B. Classification as to nature of trouble** | | | | | | | | | | | |
| 1. Flashovers | 51.0 | 58.4 | 66.8 | 42.2 | 52.4 | 54.7 | 61.5 | 48.2 | 83.6 | 54.2 | 64.5 |
| 2. Bushing failures | 3.7 | 1.7 | 3.5 | 15.4 | 0 | 0 | 1.5 | 0 | 1.8 | 4.9 | 1.1 |
| 3. Equipment failures | 0 | 2.0 | 4.1 | 7.8 | 3.6 | 0 | 0 | 6.9 | 6.4 | 3.5 | 4.4 |
| 4. Whipping conductors | 0 | 0.5 | 3.0 | 5.6 | 0 | 3.6 | 0 | 0 | 0 | 1.8 | 0 |
| 5. Conductors down—no structures reported down | 3.8 | 14.4 | 14.6 | 13.9 | 7.2 | 10.8 | 6.1 | 13.8 | 0.9 | 10.8 | 6.9 |
| 6. Failure of and damage to supporting structures | 0.8 | 11.3 | 2.8 | 9.1 | 0 | 8.3 | 0 | 0 | 0 | 4.8 | 0 |
| 7. Foreign objects—exclusive of those causing broken conductors or damaged structures, which are included in 5 and 6 above | 9.9 | 10.5 | 3.1 | 5.0 | 15.4 | 9.5 | 4.6 | 13.8 | 0.9 | 8.8 | 6.4 |
| 8. Switching | 1.5 | 1.2 | 1.9 | 0.6 | 21.4 | 13.1 | 26.3 | 10.4 | 6.4 | 5.3 | 14.4 |
| 9. Cable failure | 29.3 | 0 | 0.2 | 0.4 | 0 | 0 | 0 | 6.9 | 0 | 5.9 | 2.3 |

Explanation of items used in classification:

*Flashovers*—only cases where no damage was reported or only damage to insulators.

*Conductors down*—phase conductors, ground wires, etc.—no structures reported down.

*Equipment failure*—transformers, metering equipment, oil circuit breakers, lightning arresters, etc.

*Whipping conductors*—contacts with other conductors, line structures, or structures adjacent to line.

*Foreign objects*—wires, ropes, kites, airplane, crane boom, trees or limbs in line, blasting, etc. Accidents to persons and damage by fire.

*Switching*—includes disturbances due to switching and synchronizing under normal conditions.

| 5. Apparently self-clearing one or more times followed by final self-clearing | 2.7 | 5.5 | 3.5 | 2.5 | 0 | 0 | 1.8 | 0 | 0 | 2.8 | 0.6 |
| 6. Circuit-breaker operated but fault apparently self-clearing | 2.1 | 8.8 | 5.0 | 4.2 | 0 | 1.2 | 0.8 | 0 | 3.0 | 4.0 | 1.3 |
| Sum of items 4, 5, and 6 | 8.9 | 19.3 | 12.2 | 11.0 | 13.0 | 1.2 | 7.5 | 5.9 | 6.0 | 12.9 | 6.5 |
| 7. Records of one cycle or less duration | 12.9 | 9.6 | 19.4 | 11.9 | 24.0 | 20.0 | 16.0 | 5.9 | 9.0 | 15.6 | 10.3 |
| 8. Unable to classify | 8.8 | 8.5 | 3.1 | 11.5 | 0 | 0 | 0.9 | 2.9 | 10.4 | 6.3 | 4.7 |

have been classified as shown in table V. Wherever the word "apparent" precedes a method of clearing, this method was determined solely from the appearance of the oscillogram. In all other cases, the method of clearing was deduced from the appearance of the oscillogram in conjunction with the correlation data.

Records showing durations of one cycle or less have all been entered under item 7 of table V. Due to their short duration, it has been impossible to classify them. Some of them were due to synchronizing and switching, others were probably self-clearing short-duration disturbances. Probably in some instances the disturbance had an appreciable duration and for one reason or another the oscillograph obtained only a cycle or less of the record, thus accounting for correlation of some of them with circuit-breaker operations.

In figure 6 oscillograms *a* and *c* illustrate breaker-cleared faults; oscillogram *b* illustrates a self-cleared fault.

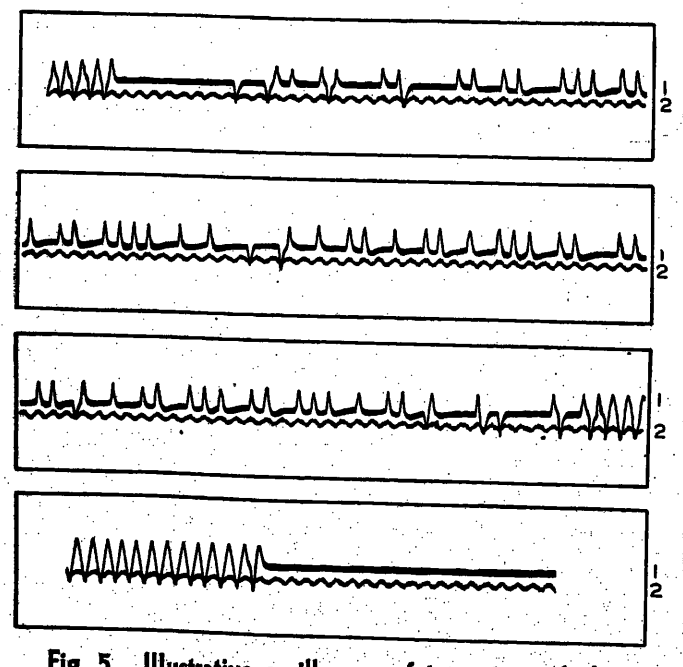

**Fig. 5. Illustrative oscillogram of intermittent fault to ground and complete final breakdown, system E**

### Faults to Ground Involving More Than One Phase Wire

In table VI is given, for systems *A*, *B*, and *E*, a classification of faults with regard to the number of phase wires initially involved and certain subsequent changes therein.

In the case of system *A*, voltages to ground as well as neutral current and negative-sequence voltage[2] were recorded, providing an accurate basis for determining the number of phase wires involved in a fault.

In the case of systems *B* and *E*, the basis for determining the condition of one or multiple line-to-ground faults was largely the appearance of the negative-sequence voltage and neutral current wave traces. The negative-sequence voltage on these systems is low for one-line-to-

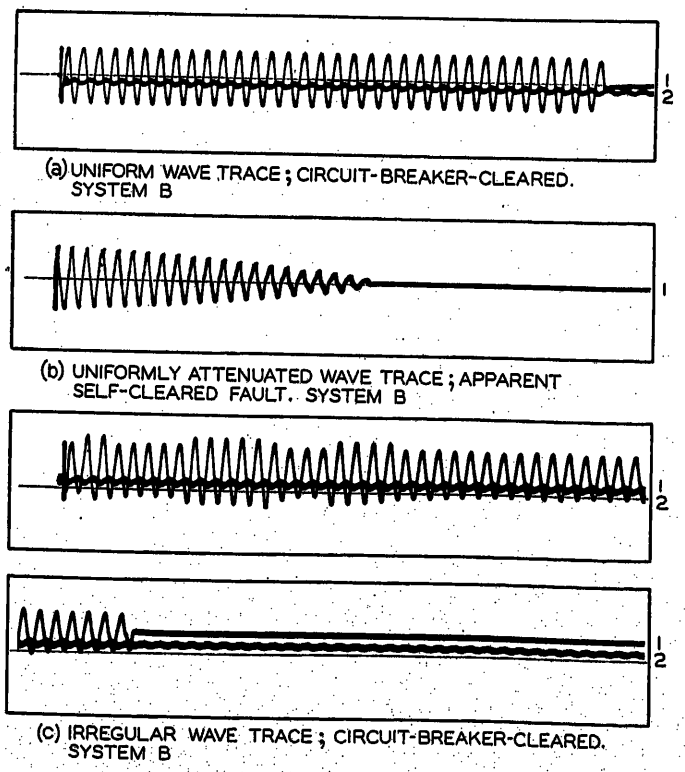

**Fig. 6. Illustrative oscillograms**

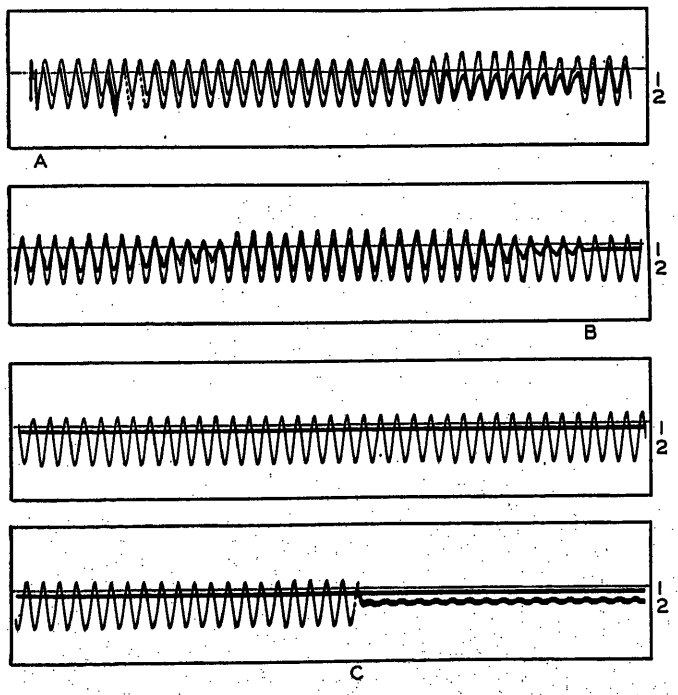

**Fig. 8. Illustrative oscillogram of development of fault from 2 line to ground (A to B) to 2 line without ground (B to C), fault self-cleared to ground and finally circuit-breaker-cleared, irregular wave trace, system B**

1—Neutral current
2—Negative-sequence voltage

ground faults and high for faults involving 2 phase wires. From inspection it is, in most instances, quite evident which ones were obtained during faults involving more than one phase wire and ground. Illustrations of this type of oscillogram are given in parts *c* and *d* of figure 7 and in figure 8. Figure 7, part *c*, indicates that the fault initiated as one line-to-ground and developed into 2 line-to-ground. The 2 line-to-ground portion of the fault is indicated by the decrease in neutral current accompanied by an increase in negative-sequence voltage. Figure 7, part *d*, and figure 8 show faults involving 2 phase wires throughout.

The neutral-current wave traces, especially in systems where neutral impedance is used, give additional information where ground faults developed from one to 2 line and then back to one line-to-ground. In such cases, an abrupt decrease occurs in the neutral-current magnitude when the second fault develops, followed perhaps by a return to the original value when one of the faults is cleared by breaker operation or otherwise. Oscillograms illustrating the changes in neutral current just referred to are shown in parts *a*, *b*, and *c* of figure 7. The validity of this method of determining the existence of faults to ground involving more than one phase wire has been verified by correlation with power-system operating records in a number of cases. Also the illustration in part *c* of figure 7, in which a negative-sequence voltage wave trace is shown, substantiates the classification of the records shown in parts *a* and *b*, thereof. In determining whether one or more than one point on the system was involved in a fault, the correlation and relay operation data were also utilized.

## Table VI—Classification of Faults Regarding Number and Sequence of Phase Wires Involved

| | Power System | | |
|---|---|---|---|
| | A–26 Kv | B–33 Kv | E–44 Kv |
| Total number of records considered | 105 | 373 | 418 |
| | Values Below Are Percentages of Total Records Considered | | |
| 1. Initiated 1 line-to-ground | 70.5 | 78.8 | 87.8 |
| 1.1 Remained 1 line-to-ground throughout | 52.4 | 67.5 | 77.5 |
| 1.2 Developed from 1 into 2 line-to-ground | 17.1 | 10.5 | 7.9 |
| 1.21 At one point | 11.3 | 4.0 | 3.8 |
| 1.22 At more than one point | 2.9 | | 1.0 |
| 1.23 Unable to classify | 2.9 | 6.5 | 3.1 |
| 1.3 Developed from 1 into 3 line-to-ground | 1.0 | 0.8 | 2.4 |
| 1.31 At one point | 1.0 | 0.3 | 1.0 |
| 1.32 At more than one point | | 0.3 | 0.2 |
| 1.33 Unable to classify | | 0.3 | 1.2 |
| 2. Initiated 2 line-to-ground | 23.8 | 17.4 | 6.3 |
| 2.1 Remained 2 line-to-ground throughout | 10.4 | 13.4 | 2.9 |
| 2.11 At one point | 5.6 | 6.1 | 1.2 |
| 2.12 At more than one point | 2.9 | 0.3 | 0.2 |
| 2.13 Unable to classify | 1.9 | 7.0 | 1.5 |
| 2.2 Developed from 2 into 3 line-to-ground | 12.4 | 1.9 | 1.7 |
| 2.21 At one point | 8.5 | 1.6 | 0.5 |
| 2.22 At more than one point | 2.9 | | |
| 2.23 Unable to classify | 1.0 | 0.3 | 1.2 |
| 2.3 Developed from 2 into 1 line-to-ground | 1.0 | 2.1 | 1.7 |
| 3. Initiated 3 line-to-ground | 5.7 | 3.8 | 5.9 |
| **Summary of Multiple Line-to-Ground Faults** | | | |
| 1. Total number of records indicating that more than one line and ground were involved | 47.6 | 32.4 | 22.5 |
| (a) At same point | 32.4 | 14.2 | 7.0 |
| (b) At different points | 9.5 | 1.1 | 2.6 |
| (c) Unable to classify | 5.7 | 17.1 | 12.9 |

No records which did not of themselves indicate multiple fault conditions were considered as such in this study, even though the correlation data indicated that more than one phase wire may have been in trouble. The reason for this was that the correlation data in many instances were not complete enough to base a classification entirely on them.

No classification of faults not involving ground could be made, since the oscillographs, in most instances, were not arranged to operate unless ground was involved. The classification was not extended beyond the first change in the number of phase wires involved. Thus, if an oscillogram indicated that a disturbance initiated as one line-to-ground and subsequently involved 2 and then 3 phase wires, the classification shows only the initiation of the disturbance and its development from a one line to a 2 line-to-ground fault.

An important reason for making this type of classification was to obtain some indication of the extent of double faults* due to overvoltage. It is felt that the development of a fault from one or 2 phase wires to a greater number of phase wires at more than one point on the power system is more indicative of the effect of overvoltage than is a fault which initiates as multiple line-to ground and remains so throughout, even though more than one point on the power system is involved. In the latter case the faults might well be caused by an electrical storm or storms extending over a large area. The percentage of total faults (and disturbances) which developed from one to multiple line-to-ground faults at different points is given below. This is a summation of the percentage figures given in table VI for items 1.22, 1.32, and 2.22. Also items 1.23, 1.33, and 2.23 of table VI, probably include some cases where the multiple fault developed at different locations.

| Power System | Neutral Resistance, Ohms | Percentage of Total Records Indicating the Development of a Fault From 1 or 2 Phase Wires to a Greater Number of Phase Wires and Involving More Than One Point on the Power System |
|---|---|---|
| *A*—26 kv | 75 | 5.8 |
| *B*—33 kv | 30 or 60 | 0.3 |
| *E*—44 kv | 150 | 1.2 |

The authors take this opportunity to thank, in behalf of the Joint Subcommittee on Development and Research of the Edison Electric Institute and Bell Telephone System, all of the companies and individuals therein who co-operated in securing the data on which this paper is based.

# Power System Faults to Ground

## Part II: Fault Resistance

By C. L. GILKESON, MEMBER AIEE  P. A. JEANNE, MEMBER AIEE  E. F. VAAGE, Member Am. Math. Soc.

## Synopsis

AN ALLOWANCE for fault resistance in fault current computations is desirable in certain types of problems. The present paper gives the results of a study made to determine reasonable values of fault resistance to use in computing line-to-ground fault currents, particularly in inductive co-ordination studies. The sources and nature of the data used in the study are described in a companion paper.[1]

## Introduction

For many purposes it is sufficient and even desirable. as in the case of certain relaying problems, for example, to assume zero fault impedance in computing fault currents. For certain other purposes, however, such as inductive co-ordination problems, it seems preferable to include in the calculations a representative value for fault impedance or to otherwise allow for its effect on fault currents.

For faults involving ground, fault impedance is generally understood to include the impedance in the path of the fault current between a phase wire at the point of fault and ground, including local ground resistance. Thus

A paper recommended for publication by the AIEE committee on power transmission and distribution. Manuscript submitted January 5, 1937; released for publication February 25, 1937.

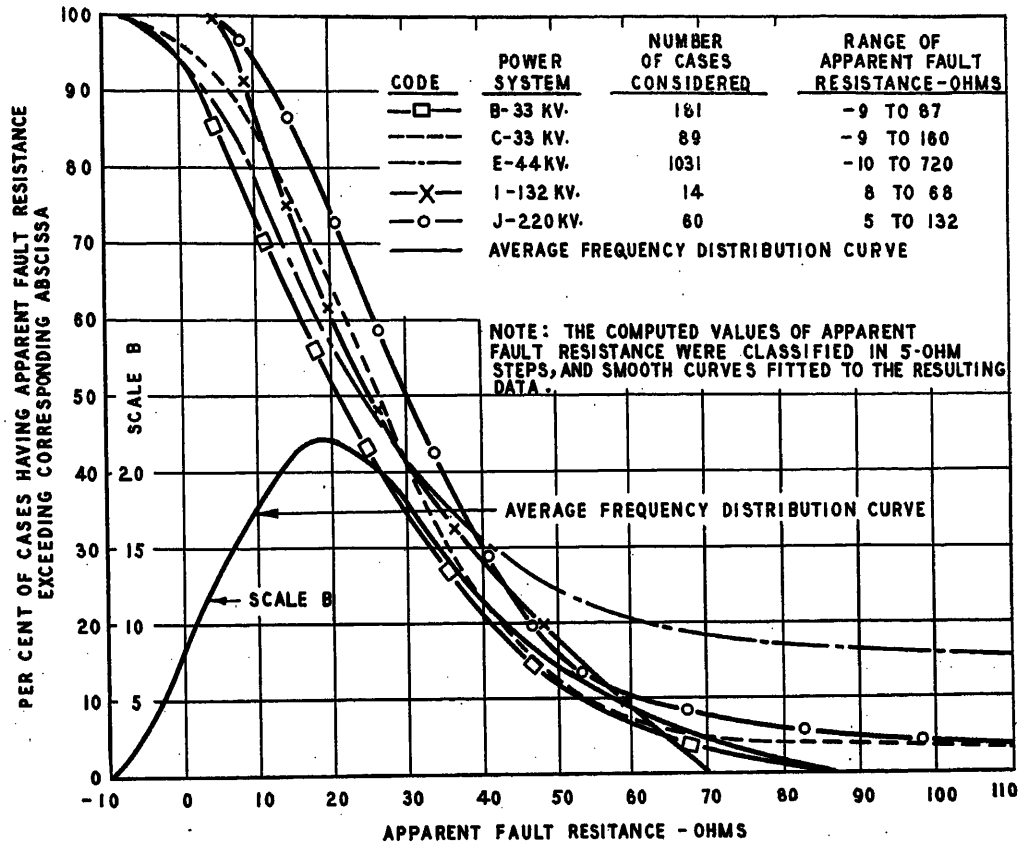

**Fig. 1. Cumulative percentage curves and average frequency distribution curve of apparent fault resistances**

fault impedance includes the resistance in the arc, in the contact between conductor and ground (in the case of wires falling on the earth), in tower footings, in a foreign object between conductor and tower (or ground) or in some combination of these factors. Fault impedance may be constant throughout the duration of a fault or it may vary continuously, as in the case of an arc which is blown out to gradual extinction by the wind. Fault impedance, in general, appears to be predominantly resistive and in this paper will be treated as though entirely so.

In this paper the approach to the problem of fault resistance is largely statistical and is based on an oscillographic study of power system fault currents, made by the Joint Subcommittee on Development and Research of the Edison Electric Institute and Bell System, in cooperation with a number of power companies. The power systems from which the data were obtained are, in most instances, referred to by a letter, i.e., system $A$, system $B$, etc. Information as to the characteristics of these systems and the nature and extent of the study on which this paper is based is given in a companion paper.[1]

The method of attack on the problem of fault resistance has, in general, been along 3 different lines:

1. Measurements of neutral current, supplemented by calculations, to determine the "apparent fault resistance" for one line-to-ground faults occurring under actual operating conditions.

2. Measurements of phase currents and voltages on a particular line to determine more directly the fault resistance under actual operating conditions.

3. Measurements (staged tests) and calculations of certain of the individual elements entering into or affecting fault resistance.

## Determination of Apparent Fault Resistance

### Theory and Limitations

For grounded systems, the formula for computing one line-to-ground fault currents by the method of symmetrical components is:

$$I_F = \frac{3E}{Z_1 + Z_2 + Z_0 + 3R_F} \qquad (1)$$

where

$I_F$ = fault current
$E$ = normal generated voltage to neutral
$Z_1$ = positive-sequence impedance of power system
$Z_2$ = negative-sequence impedance of power system
$Z_0$ = zero-sequence impedance of power system inclusive of neutral impedance but exclusive of fault resistance and capacitance to ground
$R_F$ = fault resistance (used here in preference to $Z_F$ to simplify explanation)

In case of accidental faults to ground during routine operation, $I_F$ cannot be measured directly, but in its place a measurement of neutral current at one or more points can be obtained. If there is but one neutral ground on the system $I_N = I_F$ (except for charging current); if there is more than one ground the division of the computed value of $I_F$ between the neutrals can be determined. Assuming that values of the sequence impedances of the power system are available or can be computed, that system conditions at the time of fault including fault location are known, and that measured values of one or more neutral currents under fault conditions are available, a value of $R_F$ can be determined which will make the computed value of $I_N$ equal to the measured value of neutral current.

The value of $R_F$ so obtained is of the nature of a "corrective resistance," since it includes in addition to fault resistance, the effects of differences between the actual and assumed constants of the system. Therefore, values of $R_F$ determined in this way are referred to herein as "apparent fault resistances." While this method may not give a true fault resistance, it provides a statistical

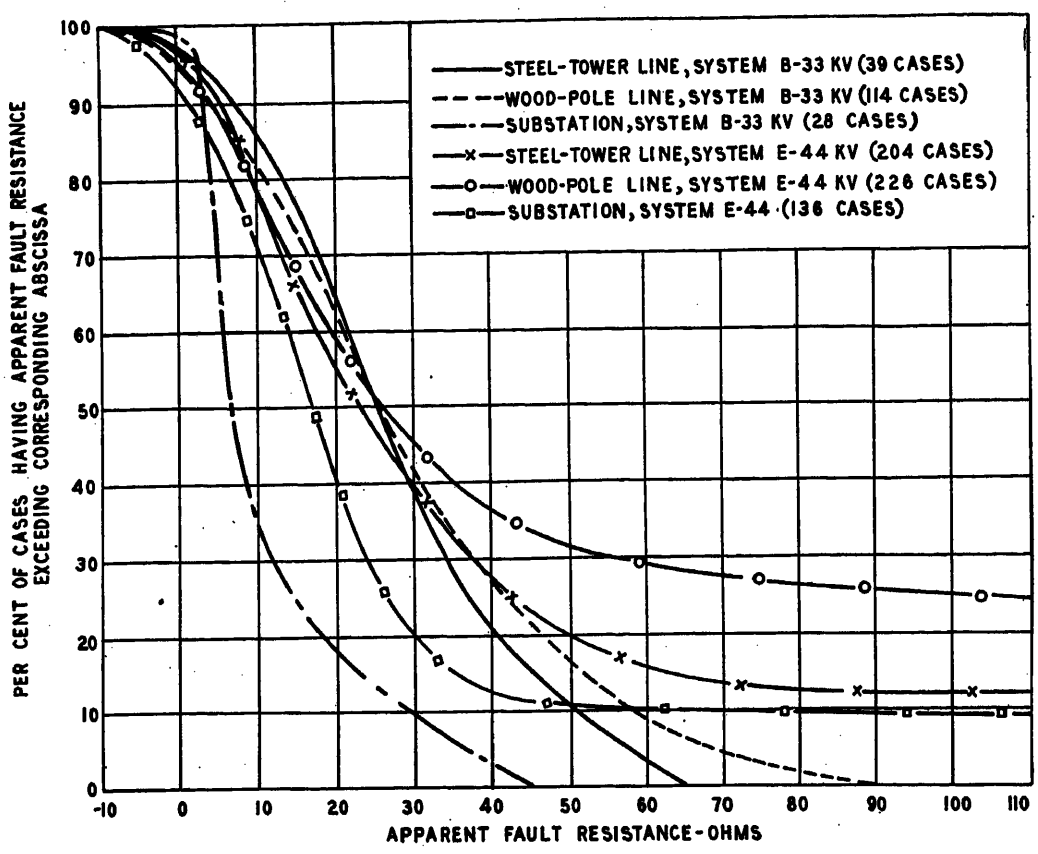

**Fig. 2. Cumulative percentage curves of apparent fault resistance for steel-tower line, wood-pole line, and substation faults**

method of arriving at a value for fault resistance for use in practical calculations of fault current. This method has been used in most of the fault resistance determinations made for this paper.

In a few of the cases a larger value of neutral current was measured than was computed under the assumption of a zero-ohm fault resistance, indicating that the conditions existing on the power system at the time of the fault, or some of the constants, were not accurately known. On directly grounded systems it will be seen, by reference to equation 1, that the largest fault current magnitude that can be calculated by varying $R_F$ (a real quantity), with other things fixed, is that which corresponds to a negative value of $R_F$ equal in absolute value to one third of the sum of the resistance components of the sequence impedances. Any assumed negative value of $R_F$ larger in absolute magnitude than this would decrease the computed fault current. In the cases used for this paper, one third of the sum of the resistance components of the sequence impedances seldom exceeded 5 ohms for the directly grounded systems. Of course, in cases where a neutral resistance is used, a negative value of $R_F$ much larger in absolute magnitude becomes mathematically possible. Negative values of apparent fault resistance, wherever indicated by the calculations, have been included and given equal weight in the analysis, although it is realized that physically they do not exist. The measured current for 2 cases from system *C*, one case from system *I* and 2 cases from system *J* so greatly exceeded the computed values that no figure for apparent fault resistance could be deduced and these cases were excluded in presenting the results.

## Results of Apparent Fault-Resistance Determinations

During some 6 years of oscillographic observations on several power systems, a total of 1,375 records were obtained for which the conditions existing on the power system at the time of fault were known with sufficient accuracy to permit computations of apparent fault resistance. The results of these computations for the 5 systems for which the data were sufficient to warrant curves are shown in figure 1.

Since these curves are similar in shape and lie fairly close together, an average cumulative percentage curve was determined from these curves and from it the average frequency distribution curve shown in figure 1 was derived. The abscissa corresponding to the peak of a frequency distribution curve is its mode, or most frequently occurring value. Similar distribution curves were also prepared for the individual systems. The modal, median, and average values of apparent fault resistance applying to the individual systems and the values from the average curve of figure 1 are shown in table I.

Systems *B* and *E* contain a considerable amount of both steel tower and wood pole line construction. The wood pole lines are not generally of the type recently advocated to take advantage of the wood insulation and some of them carry ground wires. The apparent fault resistance data for these systems were classified in accordance with the type of line to which the individual cases applied; also all apparent fault resistances deduced from substation faults were tabulated separately. Figure 2 shows the resultant cumulative percentage curves based on these classifications. For the respective systems, the curves applying to substations are much lower than those applying to lines of either type. While the curves for the steel tower lines on both systems indicate somewhat smaller apparent fault resistances than those for wood pole lines, particularly at the higher values, the modal values for these 2 types of lines are not very different for the respective systems.

Figure 3 shows average curves, based on a classification between apparent fault resistances deduced for faults on lines and at substations for systems for which such classification seemed warranted. Due to the fact that wood

**Table I—Modal, Median, and Average Values of Apparent Fault Resistance**

| System | Number of Cases | Apparent Fault Resistance | | | |
|---|---|---|---|---|---|
| | | Range | Mode* | Median** | Average |

pole lines were not of special design and frequently carried ground wires, and also to the relatively small differences between the curves for wood pole and steel tower lines just referred to in the case of systems *B* and *E*, values deduced for faults on all types of lines were lumped together in the average curves of figure 3. They show 18 ohms as the most frequently occurring value of apparent fault resistance for lines, and 5 ohms for substations.

Most of the data on apparent fault resistance were computed from values of neutral current measured 3 or 4 cycles after the fault started, which, in the majority of cases, allowed sufficient time for the disappearance of the unsymmetrical transient, if present. However, fault resistance frequently varied from cycle to cycle and in some cases, particularly on systems operating with neutral resistance, the fault cleared before breaker operation.

## Direct Measurement of Fault Resistance

A method of measuring fault resistance during accidental faults on a particular line has been suggested by W. A. Lewis as the result of his studies of distance relaying problems. The method requires the measurement, at each end of the transmission line under study, of the phase currents and the line-to-line or line-to-ground voltages, and the phase relationships among these quantities. From these measurements fault resistance and the location of the fault can be determined by solving, after some rearrangement, equations developed in connection with the theory of determining fault location in distance relaying.[2] In order to obtain measurements of required currents and voltages, at least one 6-element oscillograph is required at each end of the line.

Considerable difficulty was experienced in finding lines suitable and available for fault impedance measurements of the type described above. As a consequence, only one oscillograph installation which would provide data for this phase of the study was made, namely, that on system *D*. The oscillographs were located at each end of a 64-mile line. During the 30 months this system was under observation, 78 records of faults were obtained but only 7 were suitable for fault resistance determinations. The results are given in table II.

From the tabulation it is seen that the fault resistances determined from the 2 equations check reasonably well but that the fault locations are much less reliable, particularly for the higher values of fault resistance.

While these data are not extensive enough to add much to the information on fault resistance, the results are comparable with those given in figure 1. The observations indicated certain practical limitations in this method of measuring fault resistance. One difficulty encountered was that of adjusting the sensitivity of the oscillographs to give proper deflections for faults at any point on such a long line. Another was that of obtaining sufficiently accurate measurements of phase angles from the oscillograms. Also, with the sensitivity required to record fault currents, it was practically impossible to determine the magnitude of the load currents in the non-faulted phases, which may be a source of some error in the calculations.

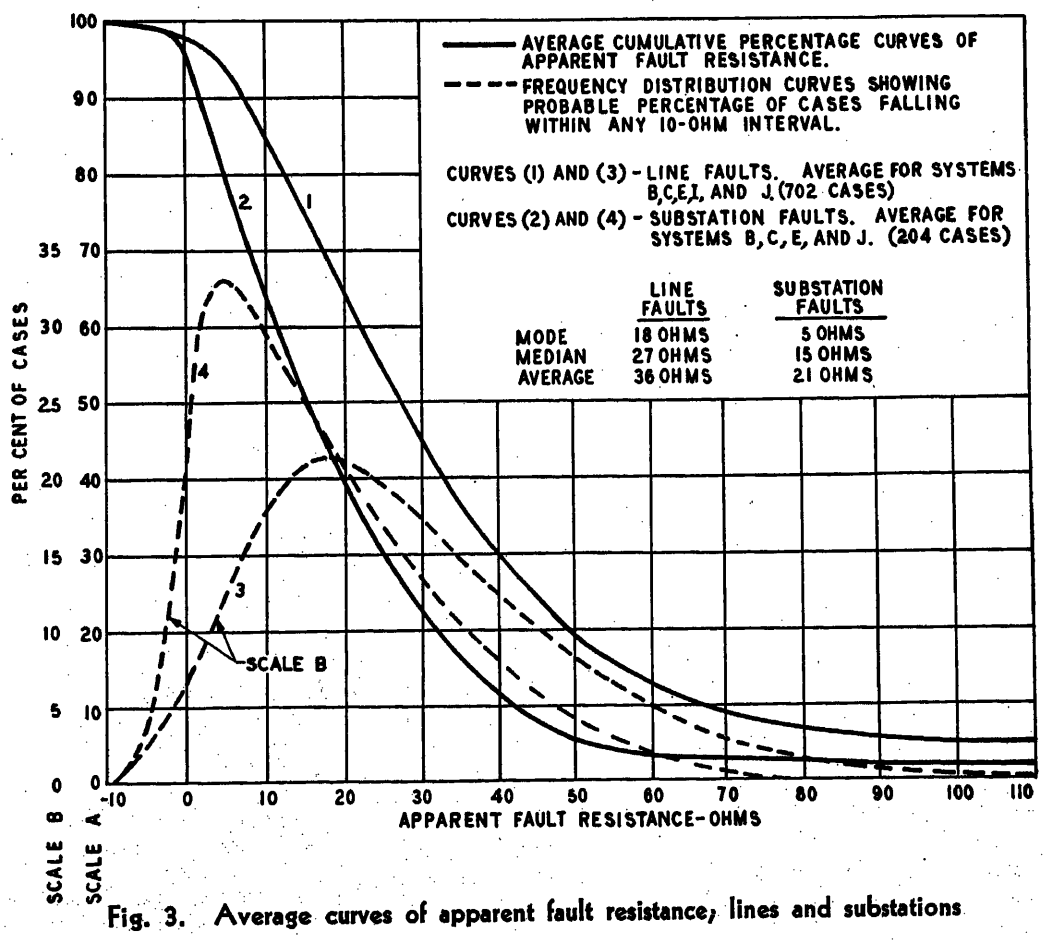

**Fig. 3. Average curves of apparent fault resistance, lines and substations**

**Table II—Fault Resistances Determined by Direct Measurements**

| Case No. | Computed Fault Location—Miles From Station G (1)* | (2)* | (Avg.) | Fault Resistance—Ohms (1)* | (2)* | (Avg.) |

## Direct Measurement of Certain Items Entering Into Fault Resistance

In the course of the fault resistance study information on certain of the items entering into or related to fault resistance has been secured. While data on all items are not available, those given may be of interest in connection with certain types of problems.

### Arc Resistance

Certain investigations have indicated that for fairly large currents, the voltage gradient in an arc is independent of current. Consequently, if the voltage per foot of arc can be determined and the length of the arc path is known or can be approximated, the arc resistance is given immediately by:

$$\text{arc resistance} = \frac{\text{arc voltage gradient} \times \text{length of arc}}{\text{fault current}}$$

From time to time advantage has been taken of opportunities to determine arc resistances and arc voltage gradients experimentally. Certain of these arc measurements, of an incidental nature, were not suitable for determining voltage per foot of arc, as no special means of determining arc length were used. The conditions under which certain of these incidental tests were made and the over-all arc resistances measured at various stages of the arc are shown in figure 4. Some additional data on arc resistance and of the arc and contact resistance of a conductor dropped on the ground are given in table III.

Some arc resistance data were also derived from a series of relay tests made on system *J*. The faults were initiated by pulling a string, saturated with a salt solution, across the arcing rings of an insulator string. The approximate lengths of the arcs were determined from moving pictures taken with one camera. The voltage gradient derived from the measurements is shown in figure 5 by the small squares in the range between 2,000 and 3,000 amperes. An average arc voltage gradient of 360 peak volts per foot was deduced from these tests.

A more detailed study of the characteristics of arcs was made in another set of tests in which representatives of the joint subcommitee participated, the results of which have been given in an AIEE paper.[3] In those tests, arc length was determined from moving pictures of the arc taken with 2 cameras set at right angles to each other. It was found that for arc currents between 100 and 800 amperes peak, 67 per cent of the measurements of arc voltage fell

| SYSTEM KV: | 110 | 33 | 33 |
| MIN. ARCING DISTANCE | 74" | 36" | 10" |
| CURRENT RANGE (PEAK ÷ $\sqrt{2}$) | 300-440 | 40-150 | 390-450 |

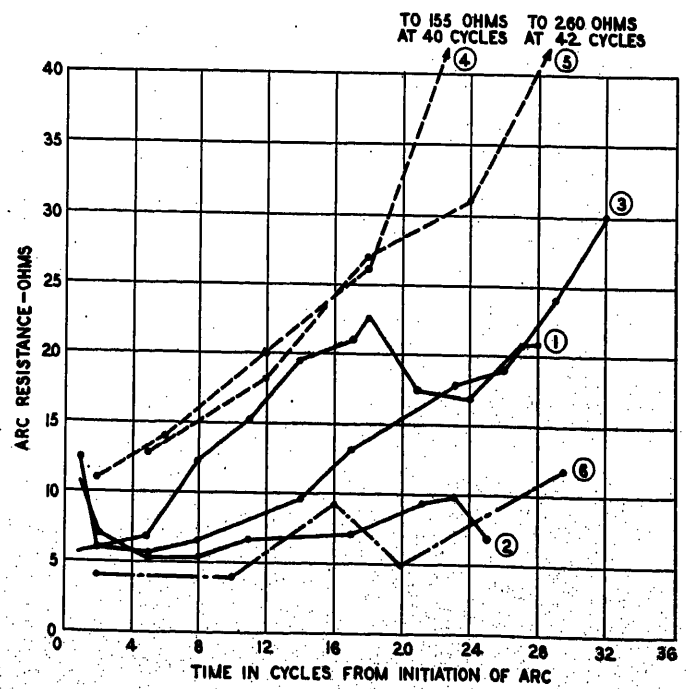

**Fig. 4. Arc resistance**

Results based on arc-voltage and fault-current measurements during staged tests on transmission lines

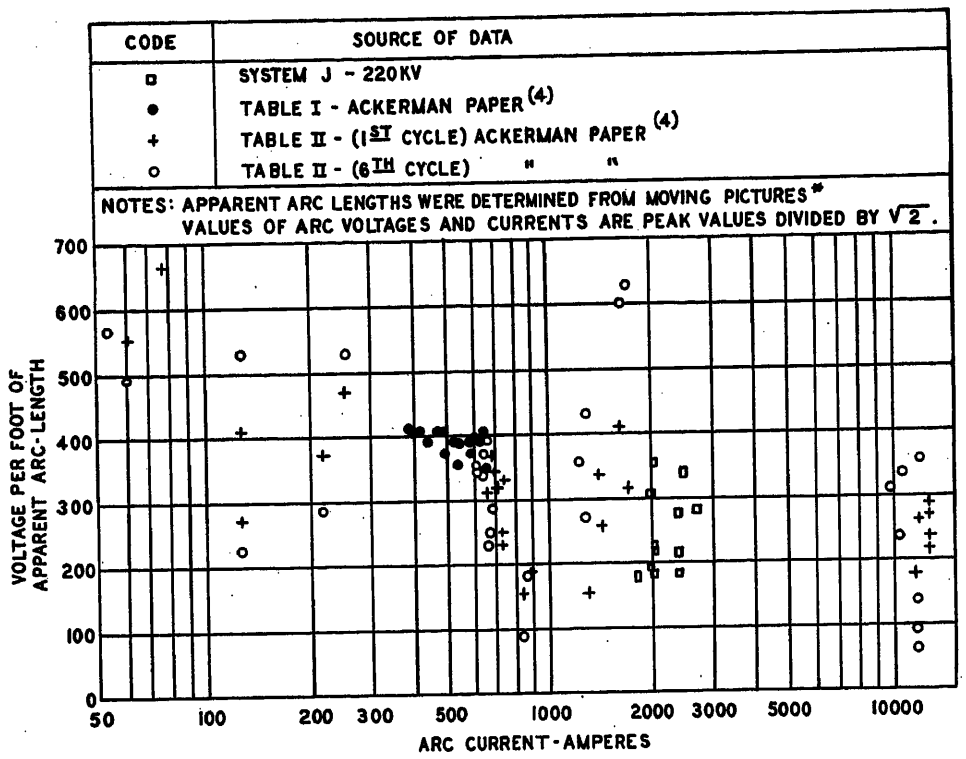

**Fig. 5. Volts per foot of arc versus arc amperes**

*Total initial arc voltage across pin type insulators for currents ranging from 70 to 10,000 amperes as given in Ackerman's paper were:

2.2-kv pin insulator—250 root-mean-square volts

27-kv pin insulator—500 root-mean-square volts

60-kv pin insulator—900 root-mean-square volts

within ±20 per cent of 300 peak volts per foot of arc length. Also 53 per cent of the cases were above 300 peak volts per foot and 47 per cent were below this value. Consequently, the average voltage gradient in an arc for currents from 100 to 800 amperes peak is concluded to be about 300 peak volts per foot.

Investigations by Paul Ackerman[4] have given valuable test data regarding the relationship between arc voltage, arc current, and arc length, the latter being determined from moving pictures of the arc (taken in one plane only). Arc lengths determined in this manner are generally greater, particularly in the case of small pin type insulators, than the striking distance across the insulator. Results from these tests, in so far as they relate to the voltage per foot of arc, have been plotted as a function of current in figure 5. On the basis of his tests Ackerman reaches the following conclusion regarding arc voltage: "The arc voltage is thus chiefly dependent on the arc length. . . . For practical purposes it may be assumed that for long stretched arcs, the arc voltage will be approximately 400 root-mean-square volts per foot length of arc, irrespective of short-circuit current."

The data from the various investigations cited above are in reasonably close agreement with regard to the voltage gradient of an arc, considering the necessary approximations in arc length. The range in average value of gradient is from 200 to 400 root-mean-square volts per foot of arc. (While root-mean-square values are quoted, it should be realized that arc current or voltage waves are usually distorted. Peak values divided by $\sqrt{2}$ were used in analyses.)

### Tower Footing Resistance

For faults to towers on lines having no ground wires, a single tower or pole footing resistance enters into the fault resistance, and unless data are available on footing resistances, the amount to allow is problematical. For lines provided with ground wires, the shunting effect of the other towers along the line becomes a factor and the importance of tower footing resistance in influencing fault current diminishes. It appears that, in a majority of cases encountered in practice, tower footing resistance on lines having ground wires, may be neglected without introducing appreciable error in fault current calculations if $l$, the length in miles of the section of line under consideration, is greater than

$$5\left(\frac{\sqrt{\text{average tower footing resistance}}}{\text{number of towers per mile}}\right)$$

This conclusion is based on a study of the effect of tower footing resistance on the zero-sequence impedance of power lines by a method given in an engineering report of the Joint Subcommittee of Development and Research, E.E.I. and Bell System.[6]

## Conclusions

(*a*) The most frequently occurring values of "apparent fault resistance" for the systems studied ranged from 5 to 25 ohms. Those determined for faults at substations were generally less than for faults on lines; those determined for faults on steel tower lines tended, for the 2 systems for which such separation could be made, to be somewhat smaller than for faults on wood pole lines, but taking the results as a whole there appears to be no marked difference for these 2 types of construction. The data indicate that, where fault resistance is to be allowed for in fault current computations, 20 ohms for line and 5 ohms for substation ground-faults are reasonable values to use.

(*b*) The direct measurement of fault resistance during accidental faults, while possible, is subject to numerous practical difficulties which make the accumulation of data by this method slow and rather expensive.

(*c*) Fairly comprehensive information on arc resistance indicates that, above about 100 amperes arc current, the

# Relation Between Voltage Drop and Load Balance in an Open-Y Distribution Circuit

By S. D. APOSTOL
ASSOCIATE AIEE

C. S. WICKSTROM
ASSOCIATE AIEE

WHEN supplying large lighting loads such as theaters, hotels, or department stores by the 4-kv primary circuits, in many cases it has been desirable to utilize only 2 phases of the 3-phase 4-wire system. These loads are fed by 2 transformers connected in open Y on both the primary and secondary. Such an arrangement is made in order to avoid connecting large lighting loads on only one phase of the 4-kv circuit, thus maintaining a better load balance on the primaries and also obtaining an economical 3-wire secondary distribution system.

With the introduction and widespread use of the a-c network system of Δ-Y transformation the connection of load to only 2 phases in open Y, in some cases, becomes necessary. This is particularly true when the load is cut from d-c to a-c and the old 3-wire system in the building is to be utilized. In both of these methods of distribution the secondary connections are essentially the same and serious voltage-regulation difficulties will arise unless the load is correctly—not generally equally—divided on the 2 phases.

It is a well-known fact that when load is fed from a 3-phase 4-wire system the most desirable arrangement would be to balance the load on the 3 phases. With balanced load, the neutral wire will carry no current and the voltage drop on all 3 phases will be equal. Any unbalancing of the load will cause the neutral wire to carry current with the result that the voltage drops will not be equal on all phases.

In this paper the effect of connecting load to only 2 phases will be considered. In figure 1, $V_A$ and $V_B$ represent the applied voltages for $A$ and $B$ phases, respectively, forming an angle of 120 degrees. Also, $I_A$ and $I_B$ represent the currents for the same phases and lagging their respective voltages. Then $I_N$ will represent the current in the neutral and its value will depend upon the magnitude and direction of $I_A$ and $I_B$. Its magnitude can be computed by the following formula

$$I_N = \sqrt{I_A^2 + I_B^2 + 2I_A I_B \cos\theta} \qquad (1)$$

where $\theta$ is the angle between $I_A$ and $I_B$.

The impedance drops on $A$ and $B$ phases are represented by $V_AE_A$ and $V_BE_B$, respectively. Also, the impedance drop on the neutral, causing the neutral point of the system at the load to be shifted to $N_1$, is represented by $NN_1$. Then the vectors $N_1E_A$ and $N_1E_B$ or simply $E_A$ and $E_B$ represent vectorially the voltages at the loads. Their magnitude and direction depend upon the impedance drop on each phase and the neutral and can be calculated by the following formulas:

$$E_A = V_A - I_AZ_A - I_NZ_N \qquad (2)$$

$$E_B = V_B - I_BZ_B - I_NZ_N \qquad (3)$$

where $Z$ is the impedance of the conductors.

A study of this vector diagram, which was drawn for equal loads and power factors on both phases, shows that the voltage on the leading phase at the load, $N_1E_A$ is considerably greater than the voltage on the lagging phase represented by $N_1E_B$. With the power factor of the load remaining constant, the voltages can be equalized by a definite unbalancing of the load on the 2 phases. The voltages can also be equalized by a change in the power factor of the load, as will be illustrated later.

With these fundamental characteristics of an open-Y circuit in mind it will be shown how they can be applied to produce good voltage regulation on wiring in buildings connected to 2 phases of the network system.

A study of various sizes of 600-volt rubber-insulated conductors installed in building conduits was made to determine the voltage drops at various power factors and various load balances. The resistance for these conductors was taken at 50 degrees centigrade and the reactance was calculated for an average position of the conductors in the conduit, using the formula

$$D = 2\left(\frac{S}{2} + \frac{\frac{1}{2}S}{\cos 30°}\right) = 2.153\,S$$

$$\therefore S = 0.465\,D \qquad (4)$$

where $D$ is the inside diameter of the conduit and $S$ the distance between centers of conductors.

Then, $X = 2\pi 60[14.051 \log (S/r) + 1.524]\ 10^{-5}$, $r$ being the radius of wire.

It was also assumed that the phase wires and the neutral were of the same size.

The calculated values for the reactance are shown in table I.

With the computed reactances and given resistances of these conductors, as shown in the table, calculations can be made using formulas 2 and 3 determining the voltage drops on the leading and lagging phases for various power factors and various load balances. Such calculations were made for number 4 wire with balanced load on both leading and lagging phases at various power factors, and the results were plotted as shown in figure 2. A study of these curves shows the following facts:

1. With the load remaining constant, an increase in power factor from 0.7 to unity results in an increase of voltage drop on the leading

A paper recommended for publication by the AIEE committee on power transmission and distribution; manuscript submitted January 8, 1936; released for publication February 3, 1937.

S. D. APOSTOL is circuit design engineer with the Commonwealth Edison Company, Chicago, Ill.; C. S. WICKSTROM is assistant supervisor of service investigation with the same company.

phase, whereas on the lagging phase the voltage drop decreases with an increase in power factor.

2. At 0.7 power factor the voltage drop on the lagging phase is more than twice the drop on the leading phase, while at unity power factor the voltage drop on the lagging phase is less than that on the leading phase. It is apparent that at approximately 0.98 power factor the voltage drops are equal on both leading and lagging phases.

Similar computations were made for number 4 wire with constant power factor of 0.9 on both phases and with various load balances on the 2 phases, based on 100-ampere total load. The results of these calculations

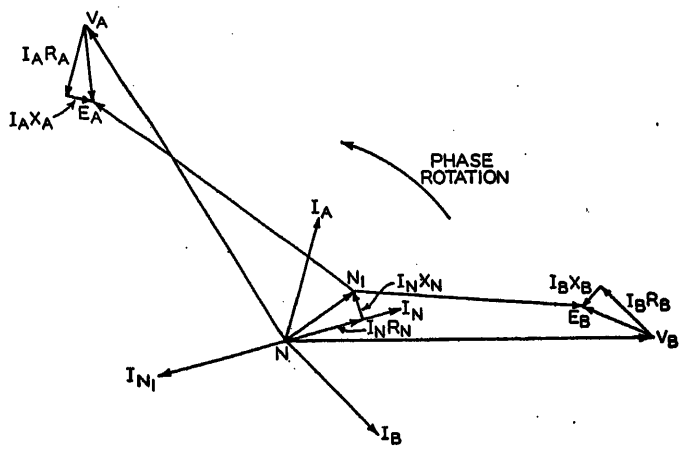

**Fig. 1. Vector diagram of an open-Y distribution circuit**

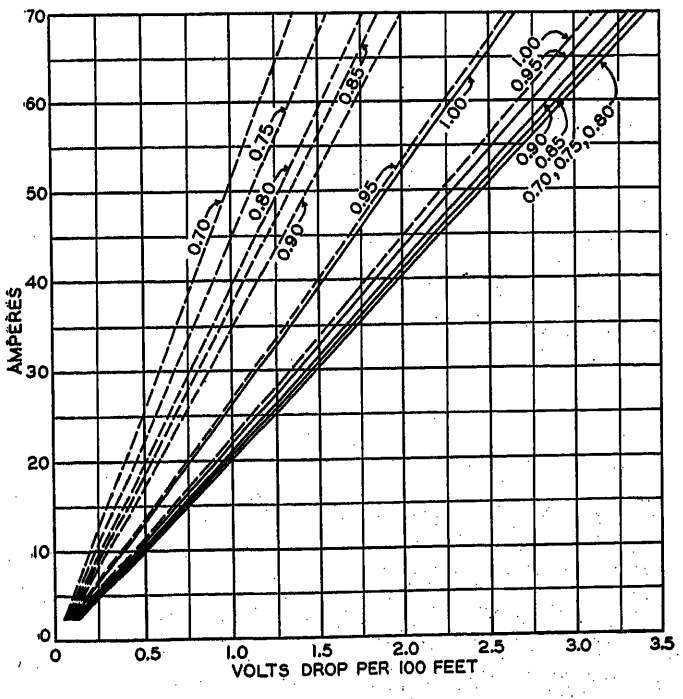

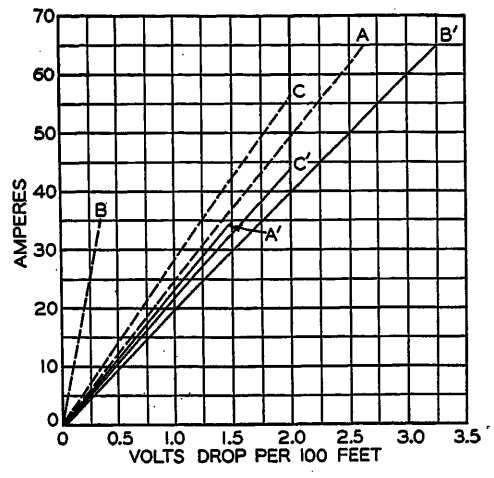

**Fig. 2. Voltage drops on leading and lagging phases at various power factors with balanced load and number 4 600-volt rubber-insulated conductors in $1^1/_4$-inch conduit**

Numbers on curves are power factors
Solid lines for lagging phase; dashed lines for leading phase

**Fig. 3. Voltage drops on leading and lagging phases at various load balances at 0.9 power factor and number 4 600-volt rubber-insulated conductors in $1^1/_4$-inch conduit**

Solid lines for lagging phase; dashed lines for leading phase

*A*—65 per cent of total load on leading phase
*A′*—35 per cent of total load on lagging phase
*B*—35 per cent of total load on leading phase
*B′*—65 per cent of total load on lagging phase
*C*—56 per cent of total load on leading phase
*C′*—44 per cent of total load on lagging phase

were plotted as shown on figure 3. It will be noted that for a load balance of 65 per cent on the leading phase and 35 per cent on the lagging phase the voltage drops are 2.65 volts and 1.5 volts, respectively. With a load balance of 65 per cent on the lagging phase and 35 per cent on the leading phase the voltage drops are 3.25 volts and 0.35 volts, respectively. The voltage drops on both phases can be equalized at 2.0 volts as shown by connecting 44 per cent of the load on the lagging phase and 56 per cent of the load on the leading phase.

Of course, unbalancing the load will increase the copper losses in the wiring but this increase has little significance when compared with the improvement in voltage regulation. It can be shown that by unbalancing the load to a point where one phase carried 30 per cent and the other phase 70 per cent of the total load, such as would be the limit of unbalancing in application, the increase in copper losses amounts to 26.6 per cent.

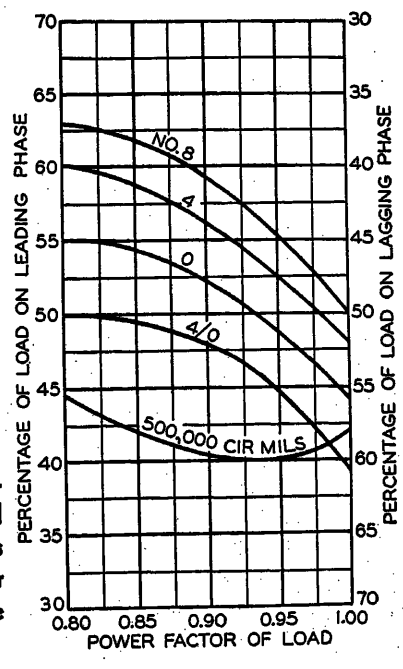

**Fig. 4A. Chart showing the proper load division between phases at a given power factor to give the same voltage drop on each phase**

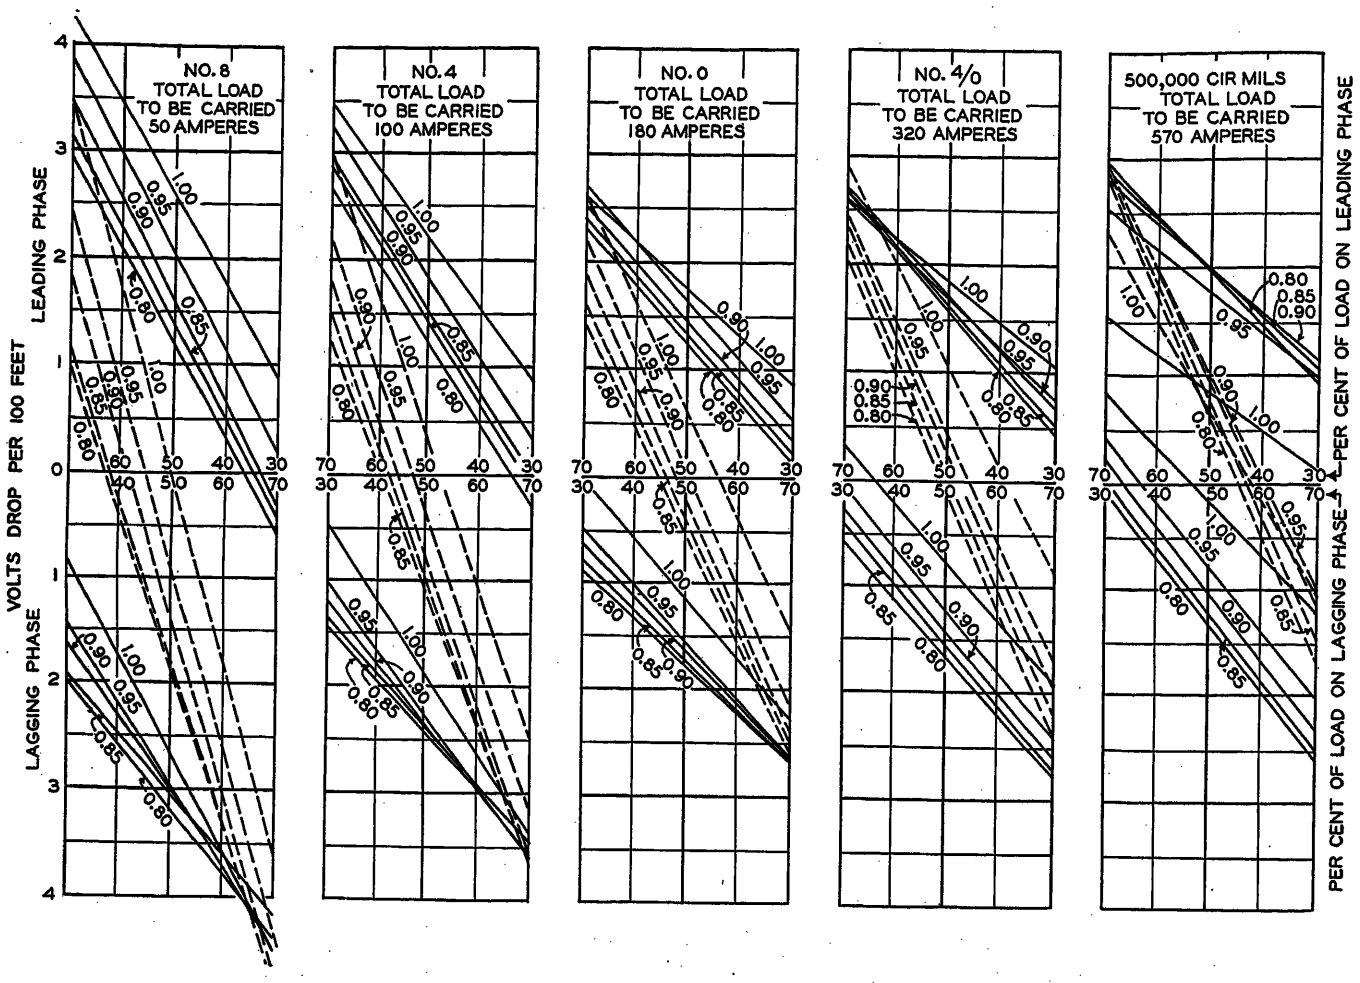

**Fig. 4. Relation between voltage drop and load balance for load connected to only 2 phases of 3-phase 4-wire secondary network for various power factors, 600-volt rubber-insulated conductors**

Numbers on curves are power factors

Solid lines are voltage drops; dashed lines are differences in voltage drops between leading and lagging phases

It has been shown that the voltage drops on both phases can be equalized by changing either the power factor of the load or the load balance. In practical application, however, the power factor is generally fixed and attention must be given to load balance. To determine the correct load balance for various sizes of conductors curves such as shown in figure 4 can be drawn. These curves show the voltage drops at various power factors and various load balances for the more generally used wire sizes. The calculations for the voltage drops on figure 4 are also based on formulas 2 and 3. Considering one phase only, say the lagging phase, and with the impedance of the phase and neutral wires equal, the formula

$$E_B = V_B - I_B Z_B - I_N Z_N$$

can be transformed by the vectorial addition of the phase and neutral currents into

$$E_B = V_B - (I_B + I_N)Z$$

or

$$E_B = V_B - I_{BN} Z \qquad (5)$$

The graphical representation of this vectorial addition for a power factor of unity is shown in figure 5. To illustrate, it is assumed that 60 per cent of the total load is connected to the lagging phase and 40 per cent to the leading phase. The vector $OP$ represents the load on the lagging phase and $OQ$ the load on the leading phase. Then $OR$ represents the neutral current for this load balance. Combining $OP$ and $OR$ vectorially, $OS$ is obtained representing the current $I_{BN}$ of formula 5.

In a similar way combining $OQ$ and $OR$ the vector $OT$ is obtained, which is the resultant of the neutral and leading phase currents. Resultants of all possible load balances, from one limiting condition where the entire load is connected to the lagging phase, to the other extremity where the entire load is connected to the leading phase, line on lines $KU$ and $LM$.

Continuing to figure 6, the lines $KU$ and $LM$ are the loci of the resultant of the current components as shown in figure 5 at unity power factor. By allowing the power factor to vary from unity to 0.8 on both phases these 2 lines will revolve about point $O$ of figure 6. The portions of the loci of the resultant currents for the neutral and lagging phase, having practical application, lie within the area bounded by the vertical lines $DD_1$ and $FF_1$ indicating

Fig. 5 (below). Diagram showing loci of neutral current and of resultant currents of neutral and phase currents for all load unbalances at unity power factor

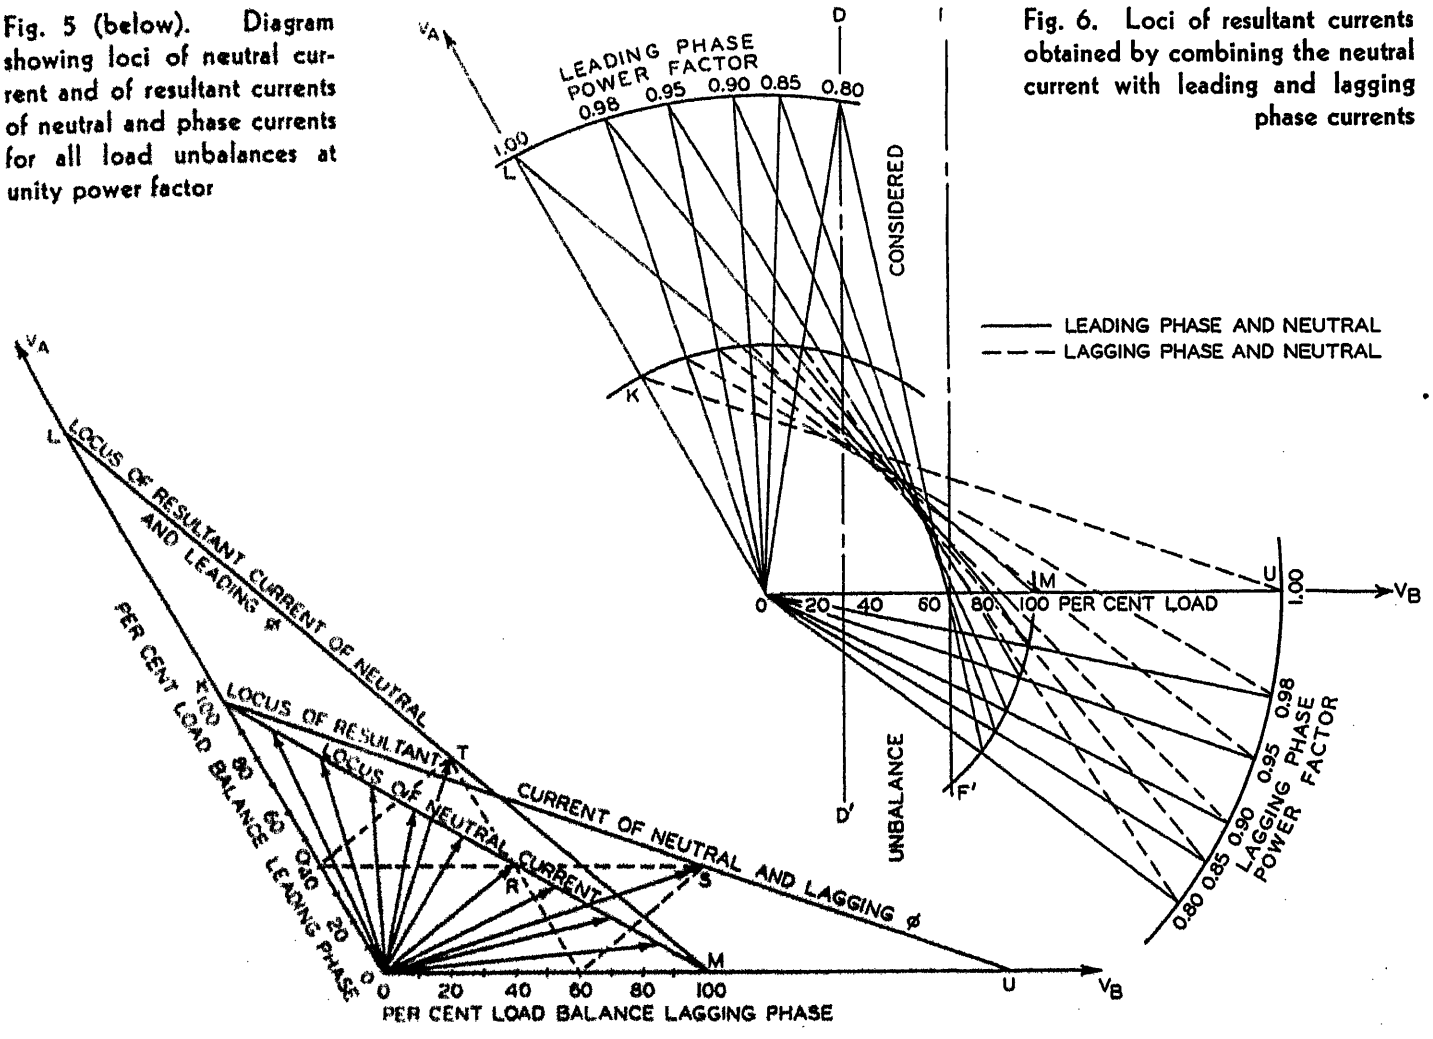

Fig. 6. Loci of resultant currents obtained by combining the neutral current with leading and lagging phase currents

load balances between 30 per cent and 70 per cent. Similarly the portions of the loci of the resultant currents for the neutral and leading phase for load unbalances between 30 per cent and 70 per cent could be segregated by lines drawn vertically to *OL* with the correct scale.

Multiplication of the resultant currents by the impedances of the conductors would give the impedance drops. Since the impedance of the conductors is a fixed value and the locus of the resultant currents is a straight line, for a given power factor, the locus of the impedance drops would also be a straight line.

The loci of the impedance drops of the various power factors will be related to one another in a manner similar to the relationship which exists between the loci of the resultant currents. From the impedance drops the voltage drops, which are desired in the final analysis, can be obtained by subtracting algebraically the voltage of the load from the applied voltage. Consequently, the loci of the voltage drops at various power factors are straight lines still maintaining the relationship with one another that existed between the loci of the resultant currents in figure 6.

From the preceding analysis the reason for the apparent inconsistency in relationship of the loci of the voltage drops shown in figure 4 is evident. It is also evident that, as the loci of voltage drops are straight lines, the determination of only 2 points on any line is necessary, thus making the drawing of the family of curves a relatively simple matter.

The curves shown in figure 4 are plotted for an unbalance of load between phases from 30 to 70 per cent. Such extreme unbalancing of the load between the 2 phases might not be practicable but it was considered for illustration purposes. As shown by the curves for a number 8 conductor and a power factor of 0.8, with the load divided equally between the leading and lagging phases, the voltage drop for the leading phase per 100

# Special Uses for the Automatic Oscillograph

By G. A. POWELL
ASSOCIATE AIEE

R. E. WALSH
NONMEMBER AIEE

THE automatic oscillograph has been available for about 7 years,[1,2] but until 8-cycle oil switches and 1-to-6-cycle relays were in general use, the automatic oscillograph was not used extensively because the performance of the slower relays and switches could be checked at low cost by various forms of high-speed graphic meters. With the present high-speed relays and oil switches, the automatic oscillograph is considered almost a necessity.

Automatic oscillographs are of great assistance in analyzing system disturbances[3,4] because they provide at reasonable cost an accurate record of what happens electrically during each disturbance. For instance, the oscillogram of a disturbance shows the duration of the disturbance, the time required for relay and oil-switch operations, the phases involved, the minimum values of voltage, any tendency toward instability, the blowing out and restriking of arcs, the amount of short-circuit current, and the amount of current in the neutral of transformer banks.

The general nature and benefits of the automatic oscillograph are well known. However, it is sometimes difficult to justify the installation of one if its only use is to analyze disturbances. The purpose of this paper is to describe other uses and to give the operating results which have been obtained.

The 3 special uses described are:

1. Fault location on transmission circuits.
2. Testing carrier-current-controlled relay system.
3. Keeping a check on the operation of the relays controlled by carrier.

The first is applicable to most systems and has been used to some extent, but little has been published on the results obtained.[5] The second is a typical example of the possibility of using the automatic oscillograph for special tests instead of requiring a portable laboratory oscillograph. The third is not applicable to many systems, but it indicates a method of obtaining additional information.

In 1931 an automatic oscillograph was installed at the Rotterdam substation of the New York Power and Light Corporation. Experience with this instrument was so favorable that in 1934 another was installed at the Pleasant Valley substation, for use in connection with the operation of the 132-kv transmission circuits to New York City.

Figure 1 shows the diagram of the transmission circuits centering at Rotterdam and Pleasant Valley.

A paper recommended for publication by the AIEE committee on instruments and measurements. Manuscript submitted September 28, 1936; released for publication February 17, 1937.

G. A. POWELL is engineering assistant of power control, New York Power and Light Company, Albany; R. E. WALSH is an engineer with the same company.

1. For all numbered references see list at end of paper.

The Pleasant Valley oscillograph is initiated by an overcurrent relay in the neutral of the transformer banks, and by a high-speed undervoltage relay. It records the following quantities:

(*a*) Three phase-to-phase 110-kv voltages.
(*b*) Current in *A* phase of Pleasant Valley-Millwood number 9,825.
(*c*) Current in *C* phase of Pleasant Valley-Millwood number 9,826.
(*d*) The total current in the neutrals of 4 transformer banks.

The Rotterdam oscillograph is started by an overcurrent relay in the neutral of the transformer banks, and records the following quantities:

(*a*) Three phase-to-phase 110-kv voltages.
(*b*) Current in *A* phase of Spier-Rotterdam number 2.
(*c*) Current in *C* phase of Inghams-Rotterdam number 9.
(*d*) The total current in the neutrals of 2 transformer banks.

## Fault Location on Transmission Circuits

The current flowing in the Pleasant Valley and/or Rotterdam transformer bank neutrals has been calculated by the method of symmetrical components for faults at the terminals of each 110-kv and 132-kv circuit, and at several intermediate points along each circuit. These calculations were started in 1932. Curves have been made for each circuit plotting Pleasant Valley or Rotterdam transformer bank neutral current versus tower number. Figure 2 shows these curves for both Pleasant Valley and Rotterdam neutral currents for faults on one of the Rotterdam-Pleasant Valley circuits. For each pair of circuits on the same towers, there are the following curves:

(*a*) Single circuit single-phase-to-ground faults.
(*b*) Double circuit single-phase-to-ground faults.
(*c*) Single circuit 2-phase-to-ground faults.
(*d*) Double circuit 2-phase-to-ground faults.

Since all calculations have been for faults of zero impedance, the actual current in the transformer bank neutrals measured by the automatic oscillographs deviates slightly in some cases from the calculated value. When a fault is found, its location is plotted on the curve sheet to show the relation between actual and calculated tower number. The phase-to-phase voltages shown on the oscillograms have been used on several occasions to calculate the approximate location of 3-phase faults.

As soon as possible after a fault occurs, the films are developed by a member of the substation crew, in dark rooms provided at Pleasant Valley and Rotterdam. The values of the 6 elements shown on the film are carefully

measured at the substation and telephoned to the power control office. Figure 3 is a typical oscillogram. The measured values on the oscillograms are converted to actual system voltages and currents from calibration curves for each oscillograph. From the voltage records on the oscillogram, the phase or phases involved is ascertained. The curve for that type of fault is then referred to, and the tower number determined. Maps showing a profile of the terrain traversed by the circuit, and the tower-footing resistances are studied to see if these factors are likely to change the location of the fault as determined from the curves. The tower number and phases involved are given to the system operator who orders the circuit patrolled 5 miles each side of this tower.

This procedure has been followed since May 1935, although calculation of the location of faults was started in 1932. Previous to 1935, it was the practice to patrol the whole circuit after a trip-out. During 1935 and 1936, a total of 200 man-days were saved in patrols by this procedure. A summary of results for the last 5 years is shown in table I.

**Table I**

| | 1932-34 | 1935 | 1936 |
|---|---|---|---|
| Number of cases calculated | 35 | 25 | 18 |
| Fault within 10 towers (approx. 1.2 miles) of calculated location | 10 | 14 | 5 |
| Fault within 2 miles of calculated location | 7 | 3 | 4 |
| Fault within 4 miles of calculated location | 7 | 3 | 5 |
| Fault more than 4 miles from calculated location | 3 | 1 | 0 |
| Fault not located | 8 | 4 | 4 |

## Testing Carrier-Current-Controlled Relay System

In 1933 2 parallel 132-kv circuits were equipped with carrier-current-controlled relay protection.[6] Standard power-directional and ground-directional relays are used for this protection. There are 2 ground-directional relays, one for starting carrier transmission and one with 2 sets of contacts. One set of contacts is for tripping and the other set for preventing the starting of carrier transmission, in case the power-directional relay should operate incorrectly, due to a large amount of through load current at the time of an internal phase-to-ground fault. For phase-to-phase faults a power-directional relay is provided for starting carrier, and in conjunction with an induction-type overcurrent relay, is used for tripping. To increase the sensitivity and the speed of the power-directional relay at the time of a fault, the voltage restraint on this relay is supplied through the normally closed contacts of an instantaneous overcurrent relay.

The relay tripping times with this scheme of protection are approximately 6 cycles. If a fault is external to the section protected, it is necessary for either the power-directional or ground-directional carrier starting relays to operate and start transmission of carrier current, and for the carrier current to operate the receiver relay at the remote end to block tripping, before the tripping relays close their contacts. This means that for correct operation of the protective scheme all of the relays must be closely co-ordinated to be selective within 6 cycles. This selective action is not difficult to obtain if the relays are all properly adjusted as the carrier starting relays open normally closed contacts while the tripping relays are circuit closing. However, after each individual relay was

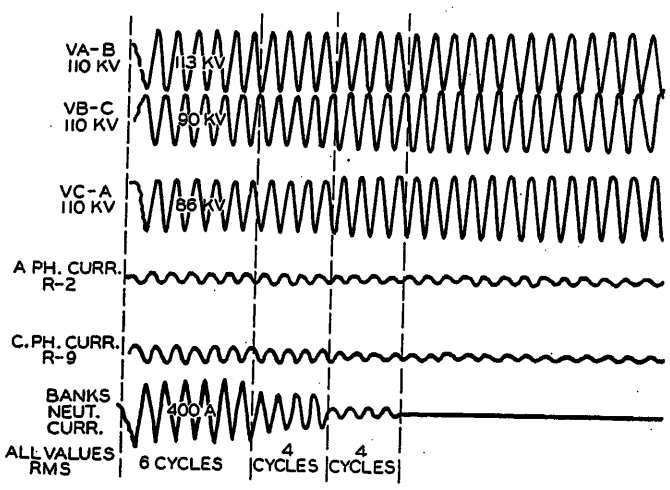

Fig. 3

carefully calibrated and set, it was felt there was no definite check on their combined operation as a group or the margin of selectivity between the groups.

In order to obtain this information the automatic oscillograph is used after each periodic calibration and check of the individual relays, to show the operation of each individual relay at that station and their combined operation as a group. One set of tests is made on the ground relays and one on the phase relays. The oscillograph is started by hand and current of proper magnitude and phase angle to simulate faults at various locations is passed through the relays and one element of the oscillograph. The relays actually remove voltage restraint from the power-directional relay, start carrier, operate the carrier receiver relay, open the trip circuit and finally close the trip circuit exactly as in actual operation, except that each set of contacts also energizes or de-energizes (depending on whether it is circuit closing or circuit opening) an element of the oscillograph from a 125-volt d-c source. One element of the oscillograph is energized with 110 volts alternating current, to give a timing wave. As soon as the tripping contacts close, the test current is removed, relays reset, and the oscillograph stopped. This procedure gives a record of the resetting of the relays as well as a record of their operation. A record of the reset

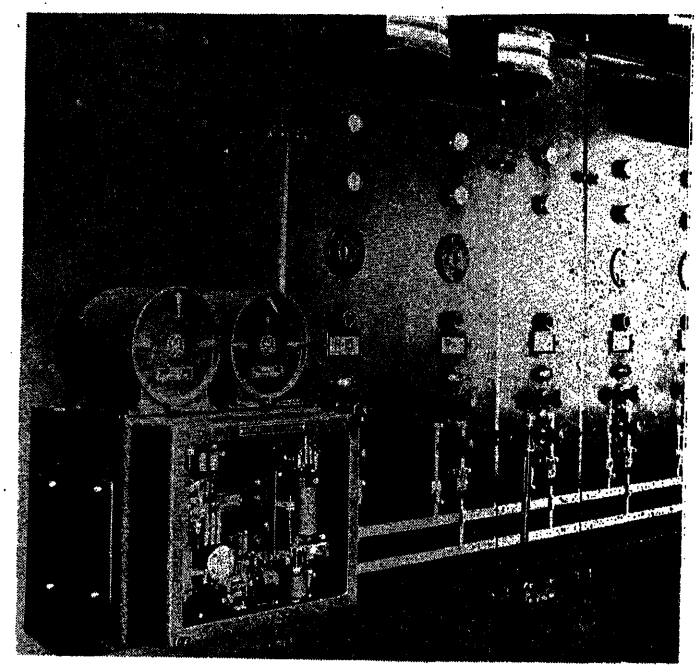

Fig. 5. Automatic oscillograph on switchboard panel in Rotterdam substation

is very important as in most cases the margin for insuring correct operation is less during reset than during operation.

## Keeping a Check on the Operation of the Relays Controlled by Carrier

After the carrier-current pilot relays had been in service about a year it was felt that although the operations had all been correct, it would be desirable to have a check of the operation of the relays oftener than the yearly periodic calibration and test. The carrier receiving relay has 2 sets of contacts; one set is circuit-opening and opens the trip circuit; the other set is circuit-closing and is used to energize an auxiliary alarm relay which lights a light and rings an alarm.

While this arrangement indicated whenever the trip circuit was locked out, it did not give any information as to the time required to lock it out or the length of time it remained open. A scheme was worked out for using the automatic oscillograph to give this information. A second auxiliary relay is connected with its coil in series with coil of the auxiliary alarm relay. The contact of this second auxiliary relay is connected in series with a 6-volt battery, a resistor, and one element of the oscillograph. The element of the oscillograph is one which is used to record one of the phase-to-phase voltages on the

# A New Magnetic Flux Meter

By GEORGE S. SMITH
MEMBER AIEE

## Summary

THE MEASUREMENT of magnetic fields in air gaps by the existing methods, is almost as cumbersome as light measurements were before the introduction of the photronic cell or photoelectric tube into that field. This paper describes a meter for the measurement of magnetic flux which seems to parallel the advance made in the lighting field.

About 2 years ago a problem arose in connection with some research work in which continuous measurement of somewhat varying magnetic flux values in air gaps was desired. A survey was made of the methods available, and no method was found suitable for the problem at hand. This problem then became the subject of somewhat extended research, the results of which are given in this paper.

A variety of schemes have been used or suggested for the measurement of air-gap flux, most of which are of value only in some very special type of problem. The 2 most popular methods in use today are first by means of a galvanometer and a search coil and, second, by means of the change in resistance a bismuth wire exhibits when placed in a magnetic field. The first of these methods requires movement of the search coil and an instantaneous reading of the resulting galvanometer deflection. The second requires careful measurement of the resistance offered by the bismuth wire in the field, as well as that in zero field; the percentage change in resistance thus obtained is referred for interpretation to a calibration curve. As is evident, both methods are cumbersome for general use, and require care and skill for accuracy. This is especially the case in the use of bismuth, since a small change in temperature between measurements will often result in a considerable error in the results. Neither of these methods is well adapted to continuous measurements.

After this research problem was well under way the author's attention was called to a publication by F. S. Dellenbaugh, Jr.,[1] describing a miniature d-c generating armature for use in the continuous measurement of magnetic fields, varying or constant. However, this method also has many disadvantages, especially from the standpoint of construction, where it is to be used in fields of very limited area, or in very small air gaps.

The first attempt in this problem was to make an instrument using the Hall effect.[2,3,4,5] This effect appears to be a distortion of the normal current path in a thin flat disk of metal in the presence of a magnetic field. Since various metals have differing Hall-effect factors, this effect seems to depend also upon some property of the material. The Hall effect for bismuth is much higher than for most other metals except tellurium. This approach appeared very hopeful until higher flux densities were approached; then the readings became less, and finally reversed in direction. Figure 1 shows the wiring diagram of the apparatus used and the curves taken for 21 degrees centigrade and 48 degrees centigrade. As has been suggested by Craig[6] and Beekert,[7] this method might be of value in the measurement of low values of flux density.

The next step contemplated was to amplify the change in the resistance of bismuth by means of a vacuum-tube circuit, but this too appeared to offer many obstacles. Finally it appeared possible to obtain the desired results by using a bismuth resistor in each of the 2 diagonally opposite arms of a Wheatstone bridge, as shown in figure 2, and placing both of these in the magnetic field to be measured.

This research has resulted in a very satisfactory method of obtaining a direct and continuous reading of the flux density of magnetic fields, either steady or slowly varying. The same instrument can be calibrated for ranges from full-scale reading of a thousand gausses or less to as high flux densities as may be desired to measure. The calibration curves for 2 ranges on the bridge are shown in figure 3. Figure 4 shows the meter with the bridge removed from its compartment, ready for use.

A study of many of the researches[8] in connection with the behavior of bismuth and other metals in the presence of magnetic fields revealed many points of value. The greatest amount of useful information was furnished by the curves shown in figure 5, plotted from data in the Smithsonian tables. These show the variations to be expected in the use of bismuth at varying temperatures and varying flux densities. Fortunately the variation over the usual working range of temperatures is not very great, so that correction need be made only when more than ordinary accuracy is desired.

Since bismuth is very brittle and is not easily worked, it is usually found pure only in lump or granular form. However, its melting point is rather low (271 degrees centigrade) and it forms well in a cast. Accordingly, it was first cast in a double spiral groove, machined in the face of a brass plate and so arranged that the resulting spiral would be noninductive. A great deal of difficulty was encountered in obtaining any great length with a small cross-section, but after many attempts 2 such spirals were obtained, of about 3.7 ohms each. These were built into a bridge, with very fine copper wire interwound between

A paper recommended for publication by the AIEE committee on instruments and measurements. Manuscript submitted December 28, 1936; released for publication February 23, 1937.

GEORGE S. SMITH is associate professor of electrical engineering at the University of Washington, Seattle.

1. For all numbered references see list at end of paper.

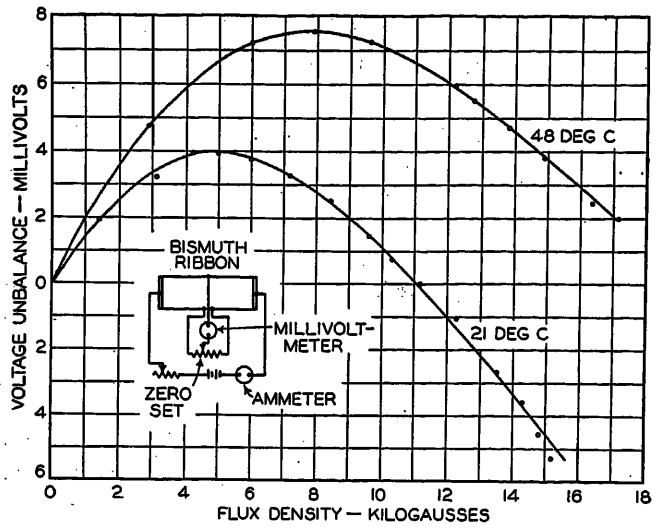

**Fig. 1. Voltage unbalance due to Hall effect**

the bismuth turns to form the remaining arms. This bridge gave such consistent results in the calibrations and various checks that still better results seemed likely from a bridge with higher resistance in the arms. Hence some bismuth wire was imported from Germany, and a bridge was constructed with 50 centimeters of 0.17-millimeter diameter wire in each spiral. Each arm measured about 28.25 ohms.

In the construction and tests on this bridge, a number of problems arose which were either partially or wholly solved.

First, since bismuth has rather high thermoelectric effect when joined to most other metals, a considerable amount of error might result if the junctions of the various ends of the spirals were not kept at the same temperature. To avoid this the support for the bridge was made of a thin sheet of copper covered on either side with a very thin sheet of mica. To each side of this support were cemented the 3 thin flat copper leads; the spirals and balancing resistors were securely attached to the one end, and a bakelite terminal block to the other. The assembly of bridge and its leads was then covered on each side by a sheet of mica, for protection. The arrangement is clearly shown in figure 6. All junctions were made as near each other as possible so that very little difference in their temperatures could exist. The resulting thickness beyond the terminal block is 1.25 millimeters. No errors from this source have been detected, so that the temperature-equalizing strip may not be necessary.

A second problem arose in the zero shift of the flux meter when the temperature of the bridge was increased or decreased. To overcome this a search was made for some metal having the same temperature coefficient as bismuth, but none could be found. By using a metal of higher temperature coefficient of resistance than bismuth, and using only enough so that its resistance change would always be equal to the corresponding resistance change in the bismuth, the zero shift could actually be made zero. The remainder of the balancing resistance for each arm can be made of manganin resistor which may be placed in the meter case. A portion of one of these should be made variable, in order to correct any possible zero displacements.

The equation used to determine the value of such balancing resistors is as follows:

$$ {}_xR_0 = {}_bR_0\alpha_b/\alpha_x $$

where

${}_xR_0$ = resistance of the balancing resistor at the assumed base temperature
${}_bR_0$ = resistance of the bismuth resistor at the assumed base temperature
$\alpha_x$ = temperature coefficient of the balancing resistor material at the base temperature
$\alpha_b$ = temperature coefficient of bismuth at the base temperature

In this research the final adjustment had to be made by trial. Since some number 40 Brown & Sharpe silk-covered nickel wire was available, it was used for the balancing resistance, though some very fine lead wire would probably be more desirable, since its specific resistance is much higher, it is entirely nonmagnetic, and it would be very easily formed in spirals.

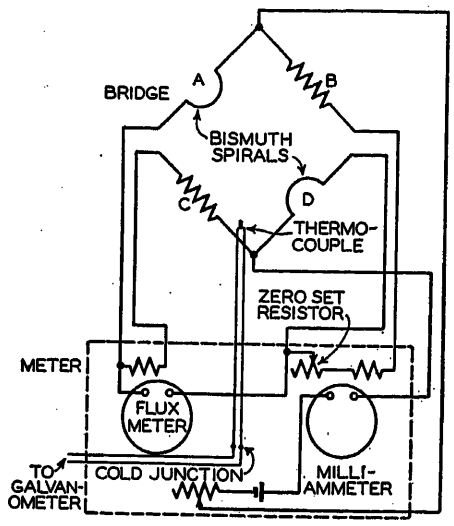

**Fig. 2. Wiring diagram for magnetic flux bridge**

The several spirals were wound separately, and each was wound noninductive. The 2 spirals of bismuth were placed between those of nickel. With this arrangement quick changes in temperature often result in uneven heating of the various spirals, and thus a temporary shift of the zero. This could be greatly reduced by interwinding the turns of bismuth and its balancing spiral.

Figure 7 shows curves of several of the tests made in studying the zero drift and in correcting it. From the great amount of data taken before the zero drift was corrected the conclusion was evident that this tendency for the zero to shift caused no noticeable error in the measurements, provided the meter was carefully set on zero before the reading, and was checked again after it. The chief difficulty arose when the zero was set in a region of zero field and then the bridge was placed near some metal whose lower or higher temperature would slowly alter the temperature of the bridge.

A third problem presents itself when the temperature of the bridge varies any considerable amount from that at which the bridge is calibrated. A study of the curves in figure 5 will show that when great difference in temperature is involved some corrections must be made, if any great accuracy is desired. In order to determine the variation to be expected in the bridge readings, a small thermocouple was built into the bridge, with the one junction placed between turns, as far into the bismuth spiral as possible. The other junction was carried back into the meter case where a thermometer could be placed in contact with it. The thermocouple was then calibrated for the difference in temperature between these junctions, and it proved to be very sensitive and very accurate. The galvanometer used was external to the meter, though the galvanometer could be built in as an integral part of the meter.

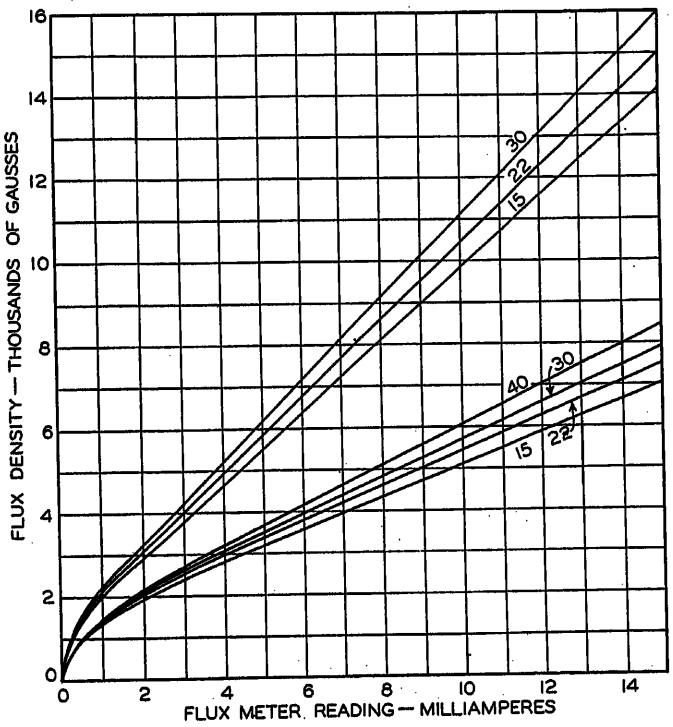

**Fig. 3. Calibration of magnetic flux bridge**

Using a model 280 Weston 1.5-milliampere d-c meter having 27 ohms resistance as flux meter
Bridge current 21.3 milliamperes for 0–7,500-gauss range; 9.8 milliamperes for 0–15,000-gauss range
Bismuth arms at 23.7 degrees centigrade—28.21 and 28.25 ohms
Nickel arms at 23.7 degrees centigrade—21.80 and 21.78 ohms
Manganin wire in meter case used for remainder of nickel arm balancing resistances
Numbers on curves are temperatures in degrees centigrade

Figure 3 shows such calibrations for several temperatures. The flux meter itself could be calibrated for the usual temperature at which it would be used, say 22 degrees centigrade, and curves could be supplied for enough temperature points above or below so that the reading could easily be interpolated for any temperature within this range.

A mathematical study of the resulting unbalance was made by assuming varying resistance values in the arms and varying currents supplied to the bridge. The wiring diagram is given in figure 8, and symbols are indicated for each of the values. The general equation for the unbalanced current in the flux meter in terms of the resistance in the arms, the flux meter resistance, and current supplied to the bridge, is

$$I_M = I_B \frac{R_4R_1 - R_3R_2}{R_1R_3+R_2R_3+R_3R_4+R_4R_1+R_1R_M+R_2R_M+R_3R_M+R_4R_M}$$

In the construction of the bridge the resistances of the 4 arms are made so nearly equal at zero flux that they may be considered equal. If then $x$ be substituted to represent the resistance of each of the 2 bismuth arms, and if $y$ be substituted to represent the resistance of each of the constant arms, the equation simplifies to

$$I_M = I_B \frac{x - y}{x + y + 2R_M}$$

For this study the bridge was assumed to be unbalanced by a flux which increased the resistance of the bismuth arms 50 per cent. Assuming the supply current to the bridge as constant, the equation was solved for varying values of arm resistance from 5 to 100 ohms and for $R_M$ values of 10 ohms and 27 ohms. The results are shown in curves $A$ and $B$, figure 8.

However, in the operation of a bridge too much heating would result if the same $I_B$ values are kept for the higher resistances, unless the size and thus the heat-dissipating capacity are altered accordingly. A second set of computations was made assuming the heat loss as constant, and thus the $I_B$ will be greater than 20 milliamperes for low arm resistances and less than that for high arm resistances. Curves $E$ and $F$ were calculated assuming a heating loss of 0.0112 watt. This was the loss allowed in the meter built, and also the resulting loss in curves $A$ and $B$ when the arm resistance was assumed to be 28 ohms.

Curves $C$ and $D$ assumed half this loss, or 0.0063 watt; curves $G$ and $H$ assumed double the loss, or 0.0252 watt.

Evidently little is to be gained by using an arm resistance more than 2 or 3 times the flux-meter resistance, even if the bridge current is kept constant for all values. As is also evident from curves $C$ to $H$, with a constant loss the arm resistance should be about equal to the flux-meter

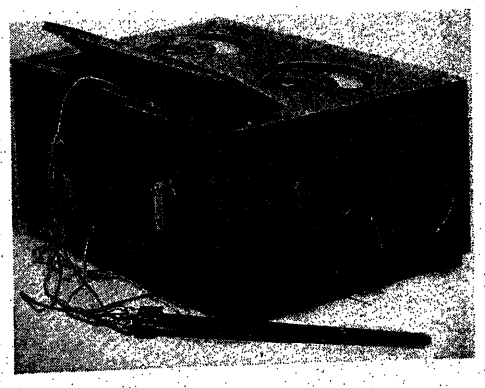

**Fig. 4. Magnetic flux meter**

resistance. Thus a desirable flux meter will have a resistance as small as possible, providing it is at the same time sufficiently sensitive. With such a meter, a bridge can be made which will be both sensitive and very small in size. Such a bridge would be well adapted to measure fields of rather small dimensions, and would give more accurate results in nonuniform fields. Since flashlight batteries would commonly be used as the source of voltage in the bridge, the current value should be kept as low as possible to give the results desired. Also 2 bridges might be used with the same meter: one with very small total area, wound of small diameter wire, the other with heavier wire and thus a much larger total area. The diameter of such a small bridge might be limited to 5 millimeters or less; that of the larger one might be 25 millimeters or more. The former would take less current, would be less sensitive, but could be used in very small field areas. The latter could be made very sensitive by using a large bridge current, but its use would be limited to uniform fields of much larger areas.

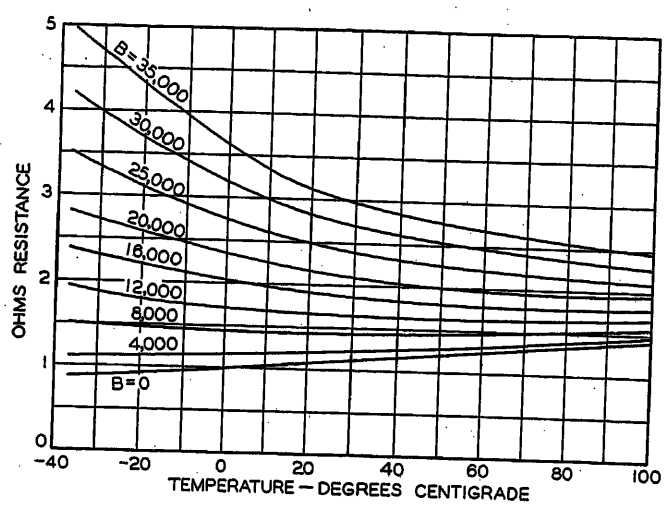

**Fig. 5. Variation of bismuth resistance with temperature at various flux densities**

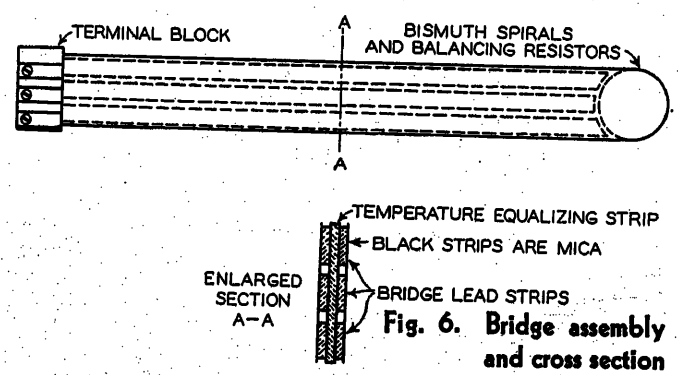
Using a resistance of one ohm at zero degrees centigrade and zero flux density (from Smithsonian tables)



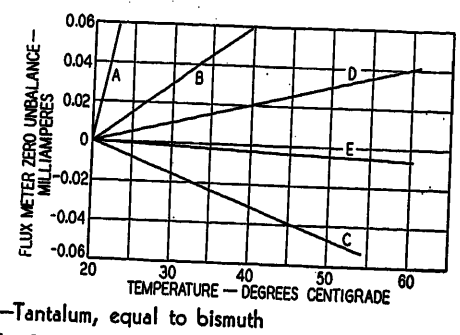


**Fig. 6. Bridge assembly and cross section**

A given meter may be calibrated to be used for a wide range of measurements. For the calibrations shown in figure 3, the range of the instrument was doubled by a reduction in the current supplied to the bridge. In a similar manner the range could be still further increased to a maximum as high as is desired. However, to obtain a lower range with the same bridge, either a greater bridge current must be used, or a flux meter of the same or greater sensitivity but with lower resistance.

The same bridge used for the curves in figure 3 had a full scale range of approximately 2,000 gausses when used with a Weston model 322 meter, having a resistance of 18.4 ohms and a full scale reading of 0.1 milliampere. By increasing the current to the bridge from 21.3 to 30 milliamperes the full scale range was further reduced to approximately 1,700 gausses.

**Fig. 7. Zero drift with temperature change**

Type and value of balance arm resistors:

*A*—Manganin, equal to bismuth

*B*—Tantalum, equal to bismuth

*C*—Copper, equal to bismuth

*D*—Nickel, approximately 18 ohms each

*E*—Nickel, approximately 22 ohms each

The final balance was too near zero to be shown on curves

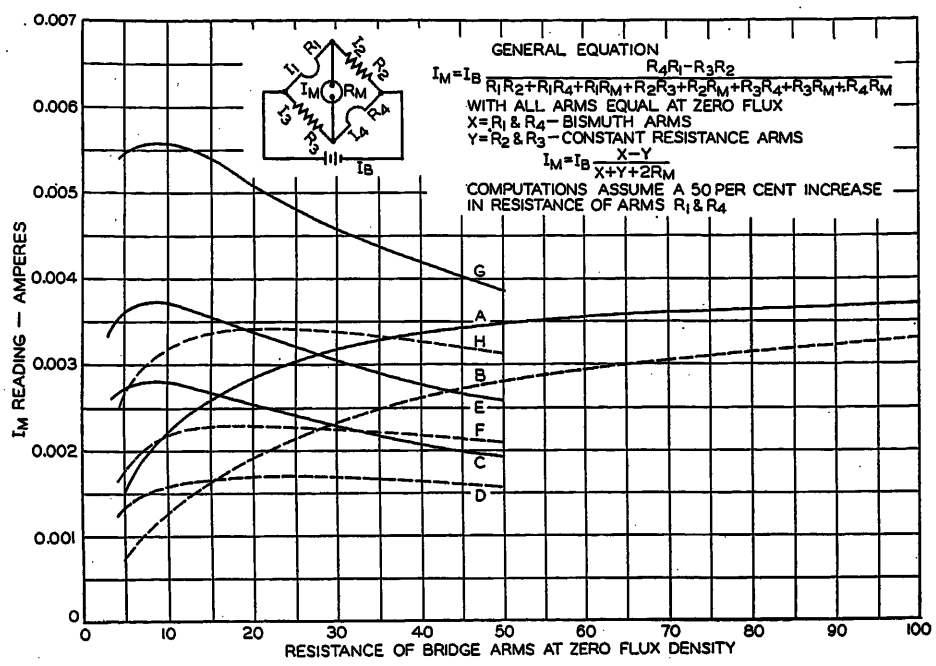
Some work was done in determining the amount of current which could be used before the heating is noticeable or dangerous. A piece of the 0.17-millimeter bismuth wire was soldered to light copper leads, and was formed into a small loop with a thermocouple inside the loop. The whole was cemented between thin mica sheets. The results showed that up to 50 milliamperes no appreciable temperature rise was noticed, and that at 75 milliamperes the temperature increased only about 2 degrees centigrade above a room temperature of about 21 degrees centigrade. The current was increased to 800 milliamperes; after about 20 minutes the wire was very hot, but still was in no danger of melting or burning out. In operating the bridge at 20 milliamperes no noticeable temperature rise takes place, and possibly higher currents could be very safely used.

For calibration purposes an electromagnet was built to give a flux density of at least 20,000 gausses between the parallel circular pole pieces, 3.8 centimeters in diameter, when the air gap between them is set at 5 millimeters. From this diameter the pole pieces taper outward at the Ewing optimum angle of 51 degrees to a final diameter of 7.6 centimeters. This setting results in a very uniform air-gap flux between the parallel faces. A one-turn search coil 2.9 centimeters in diameter is hinged on an arm and, by means of a catch, is held well within the uniform portion of the field. Beside it may be placed other measuring devices for comparison or calibration. Upon release of the arm, the search coil is automatically swung out into

**Fig. 8. Bridge sensitivity curves**

Variation of $I_M$ with varying resistance in the bridge arms

$R_M$ = 10 ohms for all full-line curves



$R_M$ = 27 ohms for all dashed-line curves

For curves *A* and *B*, $I_B$ was assumed constant at 0.02 ampere for all values of resistance. The $I_B$ current values for the other curves were computed to maintain the $RI$ constant

Curves *C* and *D*—$RI_B^2$ = 0.0063 watt

Curves *E* and *F*—$RI_B^2$ = 0.0112 watt

Curves *G* and *H*—$RI_B^2$ = 0.0252 watt

a zero-flux field by means of a spring, and the impulse due to the induced voltage is read on a ballistic galvanometer.

To calibrate the galvanometer, a standard solenoid was very carefully constructed with length 174 centimeters and diameter 7.9 centimeters, giving a ratio of length to diameter of 22 to 1. The calibration constant of the galvanometer and search coil obtained by means of the standard solenoid was 1,844 gausses per unit deflection on the galvanometer. This appeared to be fairly constant for deflections up to 4 or 5 units, but decreased by small measurable amounts at the higher values.

A calibrated bismuth spiral just received from Germany was used as a check on the ballistic method. Table I gives the results of a very careful check made between the 2 methods.

The lowest flux-density value results in a constant slightly over 2 per cent greater than the calculated one; values at the higher densities more nearly check the calculated values. As appears in table I and as was previously mentioned, the constant becomes smaller at the higher galvanometer deflections. As a compromise between the 2 methods, a curve was plotted of constants against galvanometer deflections, the values of which were taken as a reasonable mean between the 2 methods.

A considerable number of calibration data were obtained on the various bridges tried, under various temperatures and other conditions. Unusual care was taken in obtaining the curves shown in figure 3. Several check curves were taken at 22 and 30 degrees centigrade, some by means of the German spiral only and others by means of the galvanometer. Very few of the points thus obtained varied more than 1.5 per cent of full scale value above or below the mean curves, and most of the values fell on or very near the curves shown. From all the experience gained in the use of the bridge the conclusion seems reasonable that the meter will duplicate its readings to a greater degree of accuracy than can be expected from the usual calibrating apparatus, which probably ranges close to 2 per cent.

A summary of the advantages and disadvantages of the meter—most of which have been indicated in this discussion—makes evident that by the use of 2 bismuth elements instead of one, the indication for a given flux density value is very greatly increased, and that it arrives at its final value almost as soon as the element is placed in the field, remains constant if the field is constant, or varies with the field if the change is not too rapid for the meters to follow. If the various arms of the bridge are so constructed that the changes due to temperature are similar in each, small temperature changes, so troublesome with a single spiral, are entirely, or almost entirely, obviated. A single bridge and meter may be calibrated for a very wide range of flux densities, from the lowest the meter-and-bridge combination will give to the highest desired. By including more than one bridge with the same meter, the combination can be adapted for measurements in very small areas, as well as for larger areas of comparatively low densities. Probably the greatest disadvantage of the meter is the change in the indication for a given flux density when the bismuth temperature is changed either above or below that at which the meter is calibrated. Where great accuracy is desired readings must be corrected

**Table I**

| Flux Density by Bismuth Spiral | Galvanometer Deflection by Search Coil | Resulting Galvanometer Search Coil Constant |
|---|---|---|
| 2,490 | 1.32 | 1,885 |
| 7,500 | 4.00 | 1,874 |
| 10,270 | 5.55 | 1,850 |

# A Suggested Course on Industrial Economics and Business Methods

By R. E. HELLMUND
FELLOW AIEE

## Synopsis

IN VIEW of the frequent criticism of engineers to the effect that they do not pay sufficient attention to economic and business factors, a brief review of the present activities of engineers is given. It is pointed out that they are extensively and successfully handling economic problems relating directly to their specific line of work but that they are inclined to overlook other economic and business factors equally important but somewhat removed from their daily tasks. In order to stimulate the interest of the younger engineers in economics and to give them a broader viewpoint of the business enterprises in which they will be engaged, a brief but fairly comprehensive course on "industrial economics and business methods" is advocated to be given in preference to some of the highly specialized technical courses now forming part of the undergraduate curricula. The paper outlines the type of subjects which seem suitable for this course and further recommends that analytical methods of attack be employed to a greater extent than is now customary in economic studies.

The general criticism of engineers during recent years to the effect that they have not paid sufficient attention to economic and business factors surrounding their work is a challenge to the engineering profession. This criticism has almost created an impression that economic considerations are more or less foreign to practicing engineers. However, even a cursory examination of actual conditions shows that this is far from the truth. An industrial plant engineer, for example, when considering the installation of a power plant, will make very extensive and detailed economic calculations covering various plans. His studies probably would include a comparison of the economic merits of power purchased from a public utility and that generated in a privately owned plant, as without this information it is not likely that any management would appropriate funds for the undertaking. In fact, an appreciable part of the time of most plant engineers who deal with the purchase and installation of any equipment is devoted to economic studies of some kind or other. If we now turn to the design engineer, we find that he too spends a large part of his time in working out the most economic designs and in analyzing items affecting costs. A designer of household refrigerators, for instance, would not hold his position very long if he did not devote a great deal of his time to economies in design. When it is considered that with the quantities produced by some manufacturers a one-cent saving on each unit means an annual saving of $1,000 to $4,000, the need for this is obvious. Similarly, the manufacturing engineer tries continually to find ways and means for reducing manufacturing costs and in so doing makes numerous comparative economic studies. The utility engineer, in considering the extension of a distribution line to reach new customers, will as a matter of course make calculations to see whether the extension is justified from an economic point of view. In general, the time of most engineers is taken up to a great extent with economic considerations, and the majority of engineers have furthermore proved well able to cope with problems and calculations of this nature. The analytical methods required for this purpose are much simpler from a theoretical point of view than many other problems that engineers have to solve in their daily work.

Nevertheless I am in accord with those who feel that engineers should interest themselves to a greater extent in economic factors, and the suggestion frequently offered that the curricula of engineering schools be modified to bring this subject to the foreground seems a step in the right direction. Engineers who successfully handle certain economic problems too often entirely overlook other economic and business aspects, or at least do not sufficiently appreciate their importance. It is not at all uncommon to find designers who spend much of their time in devising machines that can be economically built and operated advocating commercial or engineering ventures which as a whole are economically unsound. As an illustration: In these days when air conditioning is receiving wide attention, endless schemes which could not possibly be commercialized within a reasonable period of time are being proposed by serious and capable engineers. Proposals are being made, for instance, to install internal combustion engines in homes or small commercial establishments for the purpose of furnishing both heat and electric power, and extensive studies are being made to improve the thermal and electric efficiencies of these arrangements. At the same time, the fact that this apparatus at present cannot be manufactured, marketed, and installed under a cost of several thousand dollars is being entirely overlooked. This in turn means that the interest on the investment and the allowance for depreciation and maintenance would about equal the cost at which these services can now be obtained more conveniently by using one of the existing methods of heating and by buying power from a public utility. The proponents of

A paper recommended for publication by the AIEE committee on education. Manuscript submitted January 4, 1937; released for publication February 3, 1937.

R. E. HELLMUND is chief engineer of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

1. For all numbered references see list at end of paper.

these arrangements will at times give consideration to the cost of the production of the equipment but will often entirely ignore the expense involved for sales effort, warehousing, shipping, installation, and servicing of the equipment. If this is brought to their attention, they will pass it over by stating that the distribution costs can be held low and they seem to have no appreciation of the fact that the reduction of these expenses is more difficult than the reduction of manufacturing and other more tangible factors of expense.

Similarly, the engineer who purchases equipment often acts contrary to sound economic laws by ordering special apparatus when standard apparatus would be satisfactory and more economical. The sales engineer in his eagerness to secure business will agree to furnish specials when it is obvious that this means additional expense to the manufacturer and that in the long run these expenses will be passed on to the purchaser. This practice of increasing the manufacturing cost is frequently followed by engineers who will on the other hand go into the most minute details in calculating economies in their own part of the undertaking.

This inclination on the part of the engineer to study economic factors having a direct bearing on his own work and to pay so little attention to other equally important ones entering into an enterprise is, of course, not greatly different from that found in other forms of human endeavor. It is a common failing of human nature to give undue emphasis to factors of direct and immediate interest and to overlook others of equal or even greater importance. The most natural way of eliminating this shortcoming would seem to be to give the engineer a broader point of view of industrial economics during his early education. Some schools have departments for industrial engineering in which courses relating directly or indirectly to specific phases of industrial economics are given. The titles of some of these courses indicate a rather broad study, but they are often found to be limited in scope. Nevertheless, industrial engineering students whose programs include a number of these specific courses may carry away with them a reasonably broad conception of the important factors entering into industrial economics. A review of the curricula of other engineering departments, such as the electrical, mechanical, and civil engineering, indicates that but one or 2 courses relating to a more or less specific phase of industrial economics are listed as electives, and that in a few isolated cases one or the other of these courses is compulsory. This practice, however, falls short of the previously indicated need for giving the student a broad point of view in industrial economics. In order to satisfy this need, a fairly comprehensive course on "industrial economics and business methods," relating primarily to the problem of the supply and use of manufactured goods or articles, should be given to students of electrical, mechanical, and chemical engineering. This course may also be helpful to students of civil engineering, although the interest of civil engineers is more or less confined to the use of manufactured goods and problems relating to their production are of less importance to them. It is evident that a course of this nature cannot possibly cover all phases of economics, nor can it treat any phase in detail because of the endless variety of economic problems arising in industry. Nevertheless it is believed that in a 2-hour course carried through 2 semesters, many important subjects can be covered and the student given a fairly broad perspective. An attempt will be made here to outline such a course and to indicate the type of economic studies that seem desirable as a part thereof. Frequent reference will be made to publications and textbooks containing material that seems to be suitable for supplementing the brief remarks and principles stated in the following.

The essential factors of industrial economics include:

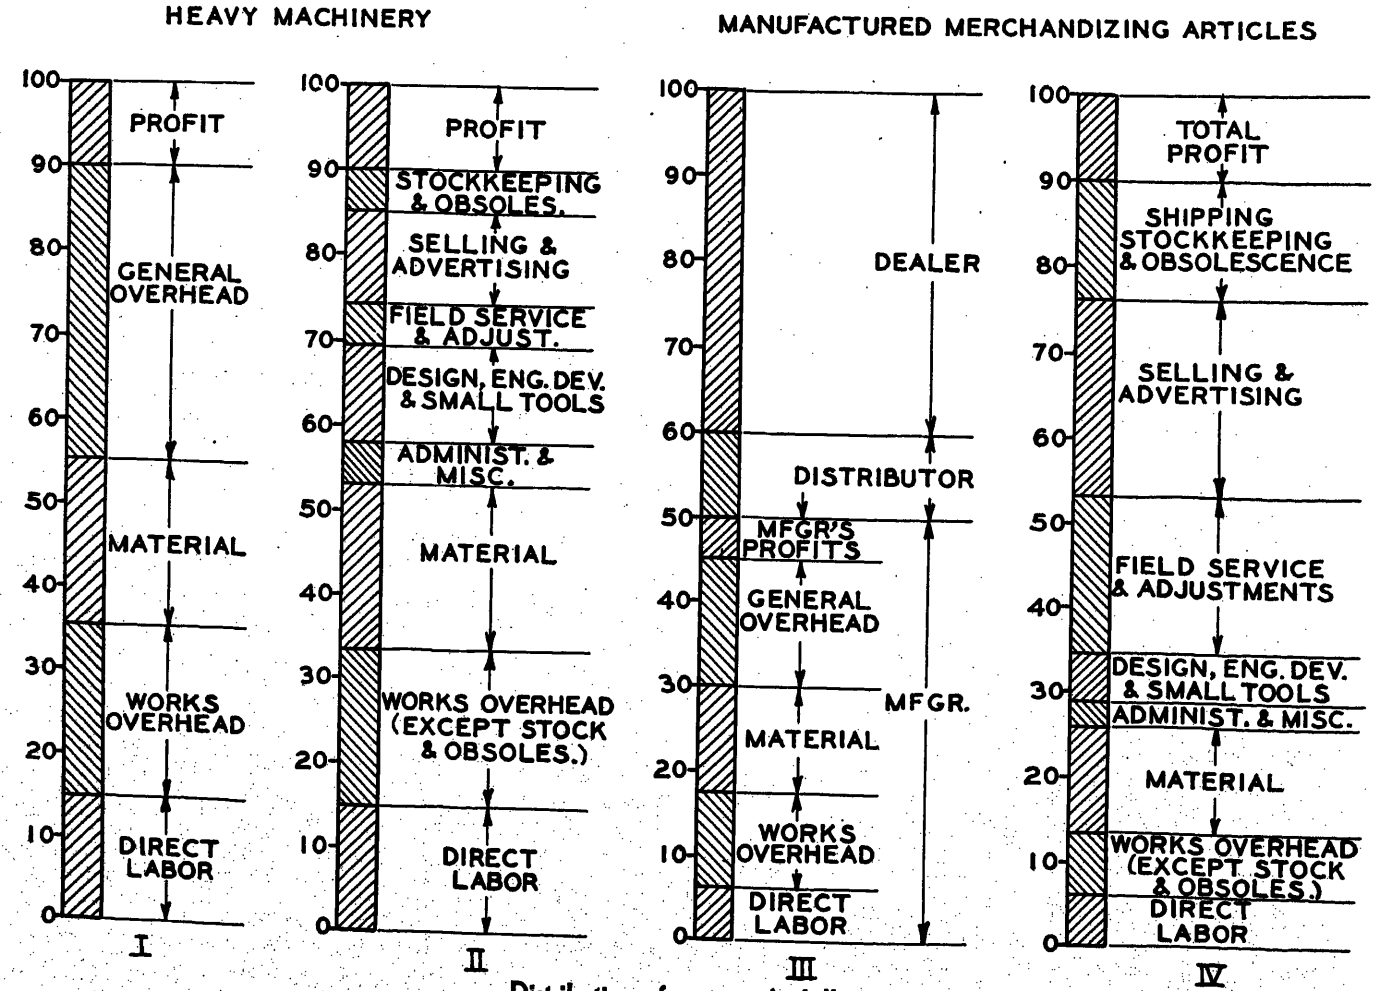
*Supplying* goods
- Direct labor
- Works overhead
- Materials
- Test and inspection
- Design, engineering development, dies, and fixtures
- Storage, distribution, and servicing
- Installation

*Using* goods
- Interest charges on investments
- Depreciation
- Operating expenses
- Maintenance expenses
- Scrap value

Factors of interest to both *supplier and user*
- Statistical methods
- Standardization
- Organization
- Personnel questions, etc.

Problems relating to the *over-all operating results* of the individual economic units
- Price limitations
- Business volume
- Expense control
- Budgeting, etc.

## A. Economics of Using Goods



Although, chronologically, the supplying of goods precedes the use of them, the supplier should give consideration first to their use. Goods are created for some use or other and only those goods which accomplish their intended purpose in the most economical manner are worth creating and marketing. The user of goods is, of course, interested primarily in this phase of economics. Often his problem is to determine whether goods purchased for a given purpose represent an economic undertaking on his part, and he should in all cases select from a number of possible choices the goods that will most economically serve his specific purpose, regardless of whether a business problem or his personal comfort or pleasure is involved. The basic principles governing these considerations are well set forth in available textbooks and therefore need not be covered here in detail. (See references 1 and 2; an abbreviated version giving the essentials presented in chapters 1 to 10 of reference 1 seems well suited for presenting this material. See also chapter 2 of reference 27 for a brief treatment of the subject.) The considerations of the user relate in the majority of cases either to

but one or to a limited number of specific applications, but the supplier's problem is much more complex. He is often confronted with the necessity of considering a great many uses of a proposed article of manufacture under various conditions of application and as affected by many economic factors. It is necessary for him to make a rather complete market analysis in order that he may supply goods which will be applicable by many users and which can therefore be manufactured in quantities sufficiently large for successful commercial exploitation. The manufacturer's point of view and methods of analysis are covered in some of the available textbooks. (See in particular reference 14, chapter 4. The considerations given in this reference apply essentially to equipment used in industry but the fundamentals apply equally well to manufactured goods of the so-called "merchandising" type used by the public at large.)

## B. Economics of Supplying Goods

### 1. Cost and Expense Factors

In a study of the economics of supplying goods, the cost factors entering into the manufacture of industrial goods should be briefly reviewed. (See, for example, chapter 7 of reference 3.) However, the distribution of goods also is very important from an economic viewpoint and the discussion should be extended to cover this phase as well. Graph I shows the cost distribution as it may apply to the manufacture and marketing of a heavy piece of machinery. This graph is in accordance with the customary accounting practice but gives only the major divisions, showing the 3 major cost factors relating to works production and giving as a single item all other factors entering into the total cost to the manufacturer under the assumption that he sells directly to the ultimate user. In graph II, the items given as "general overhead" in graph I are further subdivided, and the expense for stocking and obsolescence of stock usually involved in the handling of certain part stocks in the works organization is combined with the other expenses for stocking and obsolescence. The principal purpose of showing the expense in this manner is to stress the fact that there are, in addition to the usual manufacturing activities in industry, a number of other very definite and unavoidable functions presenting economic problems of great practical importance. Graph III shows the segregation of expenses as they quite commonly apply to merchandising articles, which require the service of distributors and dealers in addition to the function of the manufacturer in order to meet the demands of a broad market. With articles like this, certain selling and advertising expenses may be encountered by the manufacturer, distributor, and dealer, and therefore graph IV has

Distribution of customer's dollar

been drawn combining these expenses as a single item; shipping, stocking, and obsolescence as another; and field servicing and adjustment expenses as a third. This again shows that expense items other than those for manufacturing are of even greater importance than those shown in graph II. Because of the difficulty in obtaining accurate data from all 3 parties involved, no claim can be made for the accuracy of the proportions shown; however, it is believed that they are nearly correct for certain merchandising articles. These graphs are given because no suitable references could be found elsewhere.

Each of the items shown in graphs II and IV involves a number of further subdivisions, each having its own economic aspects, and it is obviously impossible to discuss all of them in a brief course. However, it seems desirable to exemplify the general principles involved by an analysis of some of the more important subdivisions and merely to mention some of the other problems of an economic nature.

## 2. Direct Labor

In the labor item, rate setting for the shop personnel is one of the most important factors subject to economic study. A great deal has been written about this (references 4, 5, and 6) and excellent results are now being obtained in this work. This subject should be covered briefly in the course (see reference 4, chapters 16 and 17). Closely tied in with the subject of rate setting is that of incentives (briefly covered in reference 4, chapter 39; see also reference 27, chapter 21). In this connection, the economic influence which incentives for speed may have upon quality and the consequent need for additional inspection and field adjustment expense, should be carefully considered. In the labor study, certain relations between production factors and the law of diminishing returns are of practical importance (chapter 8, reference 3) and may be discussed here although the broad principle applies to many activities. Another item of importance in labor costs is the determination of lot sizes giving the most economic results (reference 7). Consideration of suitable methods and equipment for all manufacturing operations and the economics of handling parts and complete pieces of apparatus in their flow from one manufacturing operation to another (reference 27, chapters 13 and 14), as well as comparisons of the merits of centralization and decentralization of some maufacturing operations (reference 24), are all essential in studies of labor expense.

## 3. Works Overhead

Equipment for manufacturing purposes represents an important item affecting works overhead. A plant engineer in considering the installation of equipment for manufacturing operations usually acts as the user of products manufactured by others and he thus makes use of methods previously referred to in the "Economics of Using Goods." In addition, he must of course compare the overhead expense caused by different types of equipment with the savings in labor costs that can be realized with each type. (See reference 27, chapter 8.) These calculations, which must allow for such factors as interest, depreciation, maintenance, cost of power, replacement, etc., are usually specific for each case, but there are basic principles which apply to all of them. (See references 1 and 8; also chapters 9, 10, 11, and 12 of reference 27.) New manufacturing equipment is an item in works overhead which must be taken into account at rather frequent intervals. There are also many other items, such as depreciation in buildings, insurance, lighting, cleaning, supervision, which require analysis less frequently but which must be reviewed at the proper time. As an example, the construction of a plant and its best geographical location involve a great many economical problems, some of which have an important bearing on works overhead expenses (reference 27, chapter 3).

## 4. Material Costs

The material content of any manufactured article is essentially a question of design, with problems more or less specific to each case. However, important general economic considerations enter into this, such as methods of standardizing and stocking raw materials which will make available a sufficient variety of materials to permit satisfactory and economical design and at the same time limit and rationalize available types and sizes of materials. This is of prime importance in reducing expenses for storage and investment and makes possible the purchase of material in large quantities, with corresponding reduction in price. (See reference 9; also chapters 6 and 7 of reference 27.) The purchase of material again involves numerous economic considerations. The methods of purchasing and the underlying basic principles represent an extensive study in themselves; only a brief reference to some of the basic considerations seems justified. (See second half of chapter 6, reference 27; for additional material see reference 22, chapters 1 and 2, and possibly reference 23, chapters 8 and 9.)

## 5. Test and Inspection

Proper inspection and testing methods for manufactured articles and parts require detailed study and are referred to separately because the expense for these activities is at times considered part of the labor cost, at times part of the cost of materials, and in other cases as a works overhead item. It is evident that articles should not be marketed without assurance, through inspection and test, of satisfactory field service in the majority of cases. Any appreciable amount of difficulty in the field will lead to uneconomical results through field expense and adjustment and the loss of the goodwill of the customer and, as a consequence, to increased sales resistance and sales expense. On the other hand, a method of inspection and testing giving 100 per cent satisfaction in the field may prove so costly as to be uneconomical from an all-round point of view. It is therefore highly desirable to devise inspection methods which strike the proper balance between the 2 extremes. Through the proper utilization of statistical data, a good deal has been done recently to put inspection activities on a more or less scientific basis and a brief study of material of this nature as part of a course on economics seems desirable. (See references 10 and 11.) While in-

spection activities are usually associated with the manufacture of goods, suitable methods are also of value to the users, who quite frequently find it expedient to undertake inspection and check tests of their own.

### 6. Design, Engineering Development, Dies and Fixtures

It is obvious that many economic considerations enter into design and engineering development activities. It has always been the major activity of the design engineer to develop apparatus which not only is effective and economical for the intended purpose but which also, through minimum expense for labor and material, can be produced cheaply. Apparatus must also be designed so that it requires the minimum expense for shop equipment and consequently low works overhead. The considerations vary to a great extent with the type of apparatus involved and can hardly be made the subject of a general study. However, a general activity which is becoming of increasing importance in economical design is that of carefully planning the design of an entire line of apparatus with all anticipated variations. With the continually increasing variety of sizes and ratings required, the multitude of service conditions to be met, and many other factors adding to the complexity of the problem as a whole, this procedure is essential. Not so long ago it was customary to design more or less independently the various sizes of a line of apparatus to meet the usual and standard requirements and subsequently to modify such designs to meet special requirements. This method of attack may still be satisfactory in cases where one type of design and possibly a few sizes or ratings represent the major part of the entire demand and where special requirements are the exception rather than the rule. In these cases, consideration of the standard variety should predominate and the few exceptions can be made the subject of secondary consideration. However, in the majority of cases such conditions no longer apply and a much better method of attack consists in designing a line of standard parts which are flexible in their use and permit the assembly of the many varieties demanded by the market. In planning a line of parts, a great deal of attention must be given to the simplification of stocking and routing of the parts so as to permit quick delivery of almost any reasonable combination and to the possibility of combining parts readily in a number of assembly plants or in the field, as the case may be. The necessity for meeting the more complex present-day problems should be recognized to an increasing extent by the designer. With the proper appreciation of this, it will usually be found possible through the choice of a rational line of parts of evenly spaced dimensions or characteristics to realize the most economical production of an entire line of apparatus with all reasonable variations rather than the production of a few so-called "standard assemblies" at a minimum cost. This can best be illustrated to the student by a few examples of specific apparatus designed in accordance with the principles previously mentioned (references 12 and 13).

Closely tied in with the development and design of a line of apparatus and usually considered as part of the development cost are the tools, such as dies, fixtures, molds, etc., needed for manufacturing the specific line as distinguished from the general-purpose tools. The expense for these tools can also be materially influenced by the planning of the entire line (see reference 27, chapter 12). Numerous problems arise in the planning of tools best suited to and most economical with the anticipated volume of manufacture, life of the design, interchangeability of parts, etc. As part of all development activities, it is very essential to determine whether the development costs can be recovered within a reasonable period from the sale of the device, the estimated sales volume being based upon previous experience or on a recent market analysis. The engineer's own work must, of course, be so planned that it can be carried on economically, and in addition to the design work, economic methods of making estimates in answer to customers' inquiries must be worked out. It is often difficult to decide whether this work should be carried on more or less completely for each individual project as it comes up or whether it is more economical to prepare extensive data which will facilitate the work in general and reduce the expense for estimating on the individual inquiries. (For additional discussion on estimating, see reference 27, chapter 5.) As part of the estimating and bidding on special apparatus, it is frequently necessary to decide whether it is more economical to accept orders involving highly specialized requirements or to forego such business. Although the decision in these cases is frequently influenced by competitors' practices, a good fundamental rule for the engineer to follow is to assume a sympathetic attitude toward those requirements for which there is economic justification or a real need and which therefore warrant a price sufficiently high to cover at least part of the extra costs of development or manufacture. (For additional discussion on engineering work, see reference 27, chapter 4.) Industrial research can be considered as part of engineering and it also has its economical aspects (see reference 27, chapter 16). However, as it is usually difficult to find a definite measure for the benefits derived from research work, it is not easy to determine just how much an industrial enterprise can afford to appropriate for this purpose.

### 7. Storage, Distribution, and Servicing

The economic problems relating to marketing and its subdivisions, such as selling and advertising, shipping, stocking, and obsolescence, installation and field service and adjustments, are often less tangible and therefore more complex and difficult than those previously discussed. This is no doubt one of the reasons why they have been subject to less analytical treatment, as a result of which less progress has been made in finding economic solutions for the many problems and in the reduction of the high costs of distribution. This, however, only emphasizes the importance of these problems and the advisability of giving them an appreciable amount of time in a comprehensive course on economics, which is further supported by the fact that a large percentage of engineering graduates take up this work after entering industry. Although there is a good deal of literature available on

the marketing of so-called "merchandise" and various business courses given at the colleges treat this subject extensively, comparatively little has been written regarding the marketing of industrial goods. However, a few good books covering this subject have been published recently and liberal use should be made of their contents in bringing before the engineering student the importance of marketing problems relating to equipment originated by engineers. (See references 14, 15, and 16; in particular, chapters 5, 6, 8, and 9 of reference 14 and chapter 2 of reference 16; also chapter 17 of reference 27.) The references given relate to the marketing of industrial equipment to industry, but it seems that there is practically nothing available on the marketing of highly technical industrial goods, such as refrigerators and electrical heating devices, to the public, though the problems in connection with this activity are becoming of increasing importance. It is evident that the methods of marketing these articles to the public differ greatly from the marketing of regular consumption merchandise, such as food, articles of apparel, and the like, and that they therefore deserve separate and thorough consideration.

In the sale of industrial products, which activity in the case of industrial products is carried on principally by engineering graduates, the success of the sales engineer depends to a great extent upon his ability to analyze his customers' problems properly from an economic point of view. It is therefore essential that he be familiar with a great many of the factors and methods of analysis outlined for the proposed course.

### 8. Installation

The installation and also the proper application of industrial products may in many cases be a major, or at least an appreciable item of expense. This expense will be incurred by the manufacturer, distributor, dealer, contractor, or user. Important economic problems may be involved but these are so varied and numerous that it is difficult to outline even the more important considerations in the brief course under discussion.

## C. Interrelation of Economic Factors

The divisions given in the graphs and discussed in the foregoing, as well as the divisions of most accounting practices and systems, represent an attempt to segregate various major types of costs or expenses and to place the responsibility for these various expenses upon the different departments of an industrial organization, such as the works, engineering, sales, and executive departments. However, these purposes are accomplished only to a limited extent, and it moreover appears to be practically impossible to devise any system which permits even an approach to a clean-cut division of responsibility among the various functional divisions of an organization. It is true that items such as labor, material, and works overhead are usually considered the major responsibility of the works organization, but the previous discussion indicates quite clearly that these items are about equally dependent on the activities of the design engineers. (Additional evidence supporting this can be found in reference 17, for instance, or reference 27, pages 52 to 58.) Similarly it can be shown that the engineering department's work appreciably influences the economic factors relating to marketing. The engineer's success in meeting, or his failure to meet, the requirements of the market and in designing for sales appeal will greatly influence the market acceptance or the sales resistance encountered and consequently will materially affect the sales expense and also the volume of sales. The latter, in turn, will indirectly influence the cost of production and so forth. The engineer also influences to a marked degree expenses for field service, field adjustments, and installation. Finally, the engineer, particularly in his ability to design parts and devices permitting flexibility of assembly and application, may affect expense for stocking, shipping, etc., appreciably and also the possibility of quick deliveries, which will directly affect sales volume and, indirectly, various production cost factors. There are few economic factors in industrial activities which are not influenced to some degree by the design and development engineer. The same holds true of the activities of the works organization. Faulty workmanship or material will result in expenses for field adjustments and will increase sales resistance and other unfavorable influences; similarly, inability to make quick deliveries because of some shortcoming of the works organization will bring with it unfavorable economic results. The sales organization in turn can materially increase engineering and development expenses by requesting estimating when there is no reasonable prospect of obtaining orders, or by accepting orders for special apparatus when standards might be sold. Examples of the influence of the activities of one division upon the economic operation of other divisions could be cited almost indefinitely. This very condition, which is practically unavoidable in modern organizations with functional activities, makes a comprehensive course on industrial economics and business methods highly desirable in an engineering curriculum. As pointed out in the beginning of the paper, almost any department can handle its own major economic problems satisfactorily, but much improvement seems possible through appreciation by any one department of the effect of its activities upon the economies of other departments.

## D. Miscellaneous Factors of Economic Importance

In addition to the activities discussed, there are a number of others the responsibility for which it is difficult to place with any one division of an organization. In these cases, results can be obtained only through the cooperation of several divisions, or perhaps even though the co-operative action of persons throughout the entire industry. Under these conditions, it is of course difficult to work out an economic solution of the problem at hand. The most outstanding item of this nature is standardization, and no course in industrial economics can be considered complete if it does not devote appreciable time to the economic possibilities of proper standardization. Not

only should the value of standardization be pointed out (see reference 3, chapter 9), but methods facilitating standardization also should be given, such as the use of simplified practice and the application of preferred numbers (references 18 and 19; also chapter 15 of reference 27). An essential step in standardization frequently consists in the choice of proper standard sizes and ratings with satisfactory steps between. This is very important from an economic viewpoint (reference 20 or 21). Some problems involved in standardization have been previously referred to in the discussion of the standardization of materials (reference 9) and the standardization and design of parts permitting flexible assembly (references 12 and 13).

Another factor which is of economic importance and which cannot be handled by the individual units is that of organization and the proper correlation of the various units to facilitate the work. The course, therefore, might make reference to different types of organization (reference 3, chapter 11). Unfortunately various treatments on organization in available textbooks are merely of a descriptive nature and some authors of articles or papers are prone to advocate in a controversial manner organizations of some particular type. In considering various types of organization, it is essential to recognize that any one of them may result in the best economic results under certain conditions, and, furthermore, that within the larger industrial organizations nearly all types of organization can be used to advantage for different activities and at different levels of the organization. For example a large company may be divided into various units, each producing a certain line of products while within each unit the organization may be along functional lines. In addition, it may be and usually is advisable to have a staff for co-ordinating certain functional activities of the various units as well as certain centralized functional activities. It is most essential that any treatise on organization should give, in addition to a description of the various types, some consideration to the factors influencing the choice of one rather than the other type of organization for any set of conditions.

Other activities usually not associated with economics nevertheless have economic aspects which may be pointed out briefly. Examples are: personnel questions, educational and training activities, and even social and welfare arrangements. (See chapter 20 of reference 27, also chapters 13 and 19 of reference 25 or chapters 14, 17, and 20 of reference 26.) The expenditure for educational activities, for instance, should be in keeping with the subsequent savings derived from having the work performed by a personnel which has benefited from such education.

## E. Analytical and Mathematical Treatment of Economic Studies

In reviewing material available on industrial economics, it has been observed that too much of it is of a descriptive nature and that there has not been much attempt to attack the problems in an analytical manner. As just indicated, the treatments of organization, for instance, are frequently descriptive or of a controversial nature and lack the objective and analytical point of view which the engineer should have in all of his work. In many instances it is quite possible to attack a problem by mathematical methods, and this is advisable even though a complete mathematical solution is not possible. Frequently even a partial mathematical solution establishes certain facts, which with the use of good judgment regarding other factors is much more likely to give better results than relying entirely on judgment. (For examples of this see references 7 and 20 or 21, also some chapters of reference 27.)

The analytical treatment of many economic problems will eventually be dependent upon statistical data and statistical methods of using these data, and for this reason some time should be given to a study of such methods, reference to which has already been made in the discussion of test and inspection (references 10 and 11). Other presentations of statistical methods for engineering problems have been published (see reference 1, chapter 14).

## F. Basic Considerations for Economic Units

An economic unit as referred to here may be an individual, a household, partnership, or a company; again, it may be a municipality, a state, a society, etc. The previous outline clearly indicates that economic considerations enter into nearly every activity connected with an industrial product, from its inception, design, or development to the time it is used up and ready for the scrap pile or to be disposed of in some way or other. Various and typical examples of economic questions have been discussed. Assuming that all industrial activities are carried out with due consideration to economy, it is further most essential that the over-all picture be sound from an economic point of view. If we assume, for instance, the simplest case where all activities are carried on within a single industrial unit, this means that the cost of creating a product must be equal to or below a value justified by its use. In addition, it is necessary that the concern involved either has the funds required to finance the venture or can convince others of the soundness of the venture and thus obtain funds from them as an investment or a loan. In most cases, however, conditions are not quite so simple inasmuch as several economic units are involved—sometimes a manufacturer and a user; again, both of these and a dealer or distributor, or both; or there may further be contractors, contractor dealers, and several other types of economic units having a place in the over-all picture. In all these cases it is necessary not only that the over-all picture of the product be sound but also the part of the work carried on by any of the individual units and the operation of each unit as a whole be on a sound economic basis. No type of unit can survive unless the other types necessary for the complete picture are able to do their part; for example, a manufacturer unwilling to give his dealers a discount which will enable them to carry on their part of the activities with a reasonable profit cannot hope to survive.

As previously pointed out, the most important economic factors of the entire picture to be considered first are those

determining the amount which the user can or will pay for a product. In the case of well-established goods for which there is a general demand, the price obtainable by any supplier is usually fixed by competitive prices, with proper allowance for difference in quality, serviceability, and similar factors. Such competitive prices as a rule drift around a level where the more efficient suppliers make a reasonable average profit. If the user is an industrial concern, the price must further be such as to make the purchase a profitable economic venture for the purchaser, based on the considerations covered under "Economics of Using Goods." In the case of individuals or homes, additional limitations are imposed by the income of the purchaser, which is comparatively low in the majority of cases. The price obtainable and the volume of sales at such price depends upon the number who are willing to pay and the amount they are able to spend for conveniences, comforts, and luxuries after paying for absolute necessities.

In view of all these and other factors limiting the price obtainable, the supplier's principal economic problem is to bring the cost of all his operations sufficiently below such price to allow a fair profit. Whenever several units, such as the manufacturer, distributor, dealer, and others, are involved in the marketing of a product, the first problem is to determine the proper distribution of the customer's dollar among these units. Subsequently each unit is confronted with the problem of carrying out its part of the functions at a cost sufficiently below the part of the customer's dollar allotted to it to insure a reasonable profit, or at least sufficient to give a fair return on the capital required for carrying on the particular activity. There are always a few exceptions to every rule, and in the case of new products of low cost and great usefulness it is sometimes possible to secure larger profits. This, as a rule, is only a temporary condition, because the very possibility of larger profits encourages competitive enterprises and consequent reduction in price. At times patent protection makes it possible to maintain larger profits for an extended period, but even in these cases attractive profits usually stimulate competitive inventive activities which eventually lead to the manufacture of similar products by others, with a resultant reduction in prices. Even during the periods when it is possible to secure large profits on the individual article, better all-round economic results can often be obtained by the manufacturer through the lowering of prices, with subsequent greater sales volume, lowered cost of production, and increased overall profits.

An outline of these considerations seems essential as a part of the proposed course and is given here in some detail because no suitable references could be found. The growing appreciation of the fact that prices and profit margins in most industries are continuously decreasing and likely to change into losses, especially during business depressions, has developed a tendency toward budgetary control of all expense and cost items, such as those shown in the graphs and many others. Continually changing business conditions naturally make it difficult to budget expenses in advance. Furthermore, too rigid a budget control carries with it the danger of interference with freedom of action when circumstances arise making departures

## Table I

| Period Number | Subject | Part of This Paper | Numbers of Typical References | Numbers of Alternate and Additional References |
|---|---|---|---|---|
| 1, 2, 3, 4 | Introduction and standardization | Introduction and first part of *D* | 3, chapter 9; 19 and 20 | 27, chapter 15; 18 and 19 |
| 5, 6 | Organization and personnel | Part of *D* | 3, chapter 11; 25, chapters 18 and 19 | 26, chapters 13, 17, and 20; 27, chapter 20 |

| 22, 23 | Materials | *B*-4 | 22*i*, chapters 1 and 2 | 27, chapters 6 and 7; 23, chapters 8 and 9 |
| 24, 25 | Design, development—dies and fixtures | *B*-6 | 12 and 13; 27, chapter 5 | 27, chapters 4 and 16 |
| 26, 27, 28, 29 | Storage, distribution, servicing, and installation | *B*-7 | 14, chapters 5, 6, 8, 9; 16, chapter 2 | 27, chapter 17; 14, 15, and 16 |
| 30 | Interrelation of economic factors | *C* | 17 | 27, pages 52–58 |
| 31, 32 | Economics of units—budgeting | *F* | 29, chapters 5, 6, and 7 | 22-*k*; 28 |
| | General references | | | 22, *a*–*k*; 30 and 31 |

The order of subjects in this table is somewhat different from that in the text; it is here arranged to give in the first semester subjects of interest to both users and suppliers and also on the economics of using goods; in the second semester, the economics of supplying goods is covered.

and changes desirable during a budgetary period. Nevertheless a gradual evolution toward methods of expense control which are sufficiently flexible to take care of changing conditions but not so flexible as to make the control ineffective seems a step in the right direction. Therefore a brief study of this subject of budgets is desirable as a part of the course under discussion. (See references 22*k*, 28, and chapters 5, 6, and 7 of reference 29.)

## G. General Discussion

No mention has been made in this outline of the economic problems applying specifically to the central station industry and its production and rate-setting activities. The outline suggested has been worked up with the idea of its being of use to all branches of engineering, such as electrical, mechanical, chemical, etc. Each of these in turn may involve economic problems more or less specific to it, such as the central station situation, which is of specific interest to electrical engineers entering the utility field. Possibly a number of courses of interest to specific types of engineering students should be offered as electives in addition to the more general course covered here; for example, a course relating to the economics of construction work might be desirable for the students of civil engineering.

Scarcely any reference has been made to economic laws and factors as, for instance, price fluctuations as influenced by the law of supply and demand, which are usually covered in existing courses on classical economics. It is assumed that the student has previously taken a course of this nature.

While this entire paper emphasizes economic considerations, care should be taken not to leave with the student the impression that all activities and practices in industry can be governed entirely by economic aspects. There are other factors which must be taken into account and several of the references given introduce points of view other than the purely economic. However, it is usually good practice in any problem or undertaking to analyze the economic situation fully and subsequently give consideration to other factors.

A review of the material given in this paper for use in a course on industrial economics and business methods might give the impression that it cannot be readily covered in a weekly 2-hour period extending through 2 semesters. However, by properly condensing the material of the references this is quite possible. Although the author has not given a course exactly as outlined here, he has given similar courses and has accumulated experience definitely demonstrating the possibility of this. Table I gives a tentative outline indicating the time which might be devoted to the various subjects. In choosing material from the references and from the content of the paper, it is more important to select it so as to illustrate sufficiently the types of economic problems and proper method of attack than it is to give an exhaustive treatment of any one of them. It also seems advisable to make predominant those economic problems which can be handled or are influenced by the rank and file of an organization in order to avoid a rather common impression among younger engineers that most economic problems are essentially a function of the management group. It has been impossible for the author to review completely all material published which might be used for the course, and the references are given principally for the purpose of suggesting the kind of material which seems desirable for this purpose; no doubt other publications of similar nature can be found which at least in some instances may prove to be more suitable for class work than that given. (See reference 22, *a* to *k*, for additional material; reference 31 gives a broad and most interesting study of American industry.)

This paper is intended merely as a contribution by one who has had practical engineering experience, and outlines subjects regarding which the young engineer entering industry should have an appreciation and understanding. It may be true that much of this material will come to the attention of most practicing engineers over a period of years, but frequently the younger engineer will be placed for extended periods in specialized work with but little contact with other divisions of the organization and he would be greatly benefited in carrying on his specialized tasks if he could bring with him some knowledge of the typical economic factors of importance in industry. (See reference 30.) It also seems that with an increased interest in economics the engineering profession could through its analytical methods of attack assist in working out more nearly correct solutions for the many perplexing economic problems in industry.

There certainly can be no doubt that a course as here proposed will be of benefit to a vastly larger number of the younger engineers than some of the specialized technical courses on such subjects as transmission engineering, electric railway engineering, communication engineering, etc., which are now taking a part of the student's available time in college. This fact cannot be ignored and steps should be taken at least to make such a course available as an elective subject and to encourage the students to take an early interest in the economic and business side of their future work.

# End-Winding Inductance of a Synchronous Machine

By B. H. CALDWELL, JR.
ASSOCIATE AIEE

## Introduction

IN PREVIOUS PAPERS it has been found necessary to consider the armature inductance of salient-pole synchronous machines under several divisions. The most useful and generally accepted divisions are as follows:

1. Inductance of armature reaction
2. Inductance due to space harmonics in the core length or differential leakage, which is subdivided into
   - *a.* Belt leakage inductance
   - *b.* Zigzag leakage inductance
3. Slot leakage inductance
4. End-winding inductance

The first 3 divisions have been adequately treated by both Alger[1] and Kilgore,[2] who have derived formulas which apply accurately for most commercial machines. Formulas for the end-winding inductance have also been given, but all of them involve approximations which have not been adequately investigated.

It will be the purpose of this paper to develop formulas for calculating the end-winding self-inductance and leakage inductance on as sound a theoretical basis as possible and to obtain a direct experimental check of the resulting formulas for the single-phase, static case. The formulas for the 3-phase case will also be derived, but no experimental check will be given at this time.

## Historical Review

Doherty and Shirley[3] were the first to develop formulas for the calculation of the armature inductance of salient-pole synchronous machines which held for a wide range of machines. Later Doherty and Nickle[4] introduced the concept of resolving the armature magnetomotive force wave into its rotating space harmonic components; and with the aid of Blondel's[5] concept of resolving such harmonics into components along the direct and quadrature axes, they developed formulas for the inductance of armature reaction and for the differential leakage inductance. They also proposed new and precise definitions for the inductances of armature reaction and the armature leakage inductance. Following the basic ideas developed in this paper Park and Robertson[6] proposed to standardize the definitions of the various types of inductances of synchronous machines, including the transient and subtransient inductances, and described methods of measuring them. At about the same time Wieseman[7] applied the technique of field plotting to salient-pole machines, which allowed an accurate determination of the constants necessary to calculate the inductances of armature reaction. With this basis Alger[1] developed more accurate formulas for armature inductance, and introduced the belt leakage and zigzag leakage inductance terms as used by Adams[8] in his treatment of induction machines. Later Kilgore[2] published a paper wherein he developed formulas for calculating armature inductance. He used essentially the same definitions as Alger, but his results were given in a slightly different form, and he gave formulas for calculating the transient inductances, and proposed the use of a saturation factor.

## Theoretical Development

The approach which will be employed in the solution of this problem follows the same general scheme as that used by Doherty and Nickle[4] in calculating the inductance of the armature in the core length. That is, the magnetomotive force will be resolved into space harmonics, and the corresponding flux density wave will be found. The linkages will be determined with the aid of the equation

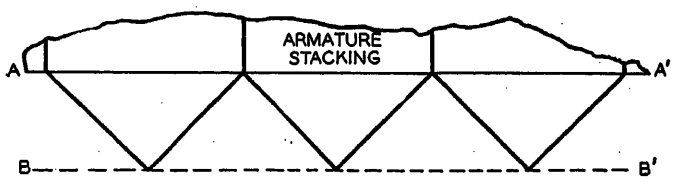

**Fig. 1. Development of simplified end winding**

of the flux density wave, from which the inductances will be found. The problem in this case differs from the core length solution in that the magnetic circuit is composed of air, and the magnetic field is 3-dimensional.

Since writing this paper attention has been called to "Potentialfelder der Electrotecnik" (a book), F. Ollendorf, Julius Springer, Berlin, wherein a similar approach is made to this problem, but the solution obtained is not so complete in detail or results.

As in the method used by Doherty and Nickle,[4] it will be assumed initially that the conductors are concentrated and have zero cross-sectional area. It will also be assumed that the end-winding coils are V-shaped. Then the end-winding will have been simplified to the winding shown in figure 1. It will also be assumed that the end-winding conductors lie in a plane which is the plane of the development of the armature surface.

The end-winding region is the region enclosed by the 2 planes $AA'$ and $BB'$ as shown in figure 1, which cut the

A paper recommended for publication by the AIEE committee on electrical machinery; part of a dissertation presented to the faculty of the school of engineering of Yale University in candidacy for the degree of doctor of engineering, 1936. Manuscript submitted October 26, 1936; released for publication February 25, 1937.

B. H. CALDWELL, JR., is in the motor and generator engineering department of the General Electric Company at Schenectady, N. Y.

1. For all numbered references see list at end of paper.

plane of the end-winding coils at right angles. The plane $AA'$ passes through the end of the armature core; thus, it is the boundary formed by the iron of the armature and field. The plane $BB'$ passes through the apices of the V-shaped end-winding coils.

In order to investigate the field in this region it is necessary to make some assumptions regarding the character of those boundaries. The iron of the armature

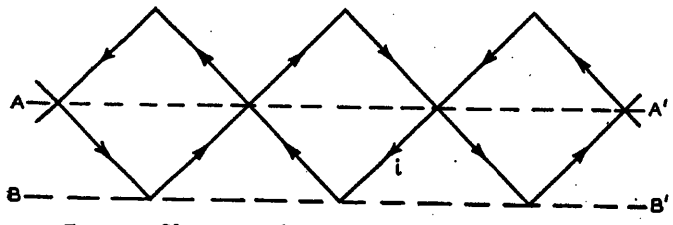

**Fig. 2. Showing substitution of a second V-shaped conductor for the armature stacking**

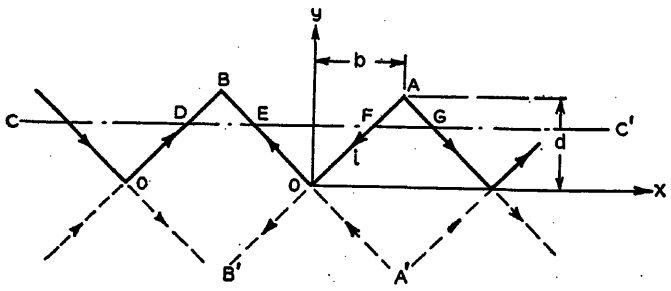

**Fig. 3. Development of simplified end winding showing the assumed image OA′ of OA, etc.**

core which forms the boundary $AA'$ will contain eddy current paths, and the flux entering it from the end-winding region must enter at approximately right angles to these eddy current paths; therefore the iron will act somewhat as a magnetic shield. In view of this fact the component of flux which is normal to the end surface of the armature core will be neglected, and the lines of flux will be assumed to be parallel to the end of the armature core at this boundary. The same boundary condition will be obtained with the configuration shown in figure 2 where a second V-shaped coil is substituted for the armature core.

The boundary condition at the plane $BB'$ will be approximated by assuming that the end-winding conductors are produced as shown in figure 3; that is, $OA$ is produced as $OB'$, etc. This assumption is made primarily to simplify the solution. It will introduce an error proportional to the coupling between coils $OAB$ and $OA'B'$ which will be discussed later.

The field in the end-winding region is symmetrical about the plane of the coil, and the problem is more easily treated by considering only the field on one side of the plane of the end-winding conductors. Because of this symmetry it is obvious that one-half of the total magnetomotive force is effective for either side of the plane of the conductors.

In obtaining a solution it is desirable to make the following simplifying assumptions and apply corrections later. These assumptions are:

1. That the end winding can be approximated by the V-shaped configuration as shown in figure 1.
2. That the conductors are of zero cross-sectional area.
3. That the end-winding conductors $AO$ and $BO$ as shown in figure 3 are produced as $OB'$ and $OA'$ and that these produced conductors carry the same current as the actual end-winding conductors.
4. That the component of flux normal to the end surface of the armature core is zero.
5. That the end-winding conductors lie in a plane which is the development of the cylindrical armature surface.
6. That the conductors in each phase group are concentrated.

Select a rectangular system of co-ordinates as shown in figures 3 and 4 with $O$, the apex of the coil, as the origin. Let $x$ be measured in the peripheral direction, $y$ in a direction parallel to the axis of the shaft, and $z$ in the radial direction perpendicular to the plane of the development. All distances are measured in centimeters. The positive direction from the $x$ co-ordinate is taken as the direction of rotation; the $y$ co-ordinate is measured positive toward the armature core; and the positive direction of the $z$ co-ordinate is taken in such a direction that a right-hand system of co-ordinates is formed. The dimensions $b$ and $d$ are measured in centimeters as illustrated in figure 3.

Select the magnetic reference potential as that existing along any line segment such as $DE$ and $FG$ of section $C$-$C$ as shown in figure 3, or in other words, the plane bounded by $OBO'B'$. In traversing a flux line $efgh$ as shown in figure 4, a magnetomotive force drop of $4\pi ni$ is experienced, where each of the $n$ conductors in the coil side $E$ carries $i$ abamperes of current. Since the field is symmetrical about the plane of $DEFG$, the magnetomotive force drop experienced in traversing $efg$ is $2\pi ni$.

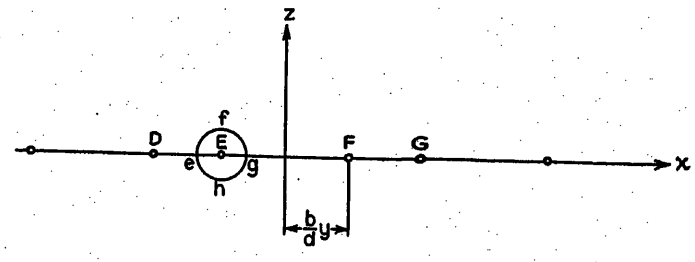

**Fig. 4. Section of the end-winding region taken perpendicular to the developed plane of the end-winding conductors**

If this magnetomotive force along a typical line formed by the intersection of the plane of section $C$-$C$ and the $x$-$y$ plane is plotted as ordinates against the distance along the line as abscissas, a curve as shown in figure 5 is obtained. The wave of the magnetomotive force along the $x$ axis for several values of $y$ is shown in order to demonstrate the variation along the $y$ axis.

If $k = (P/D)(b/d)$ and $\gamma = (P/D)\,x$, where $P$ is the number of poles and $D$ is the diameter, then the equation

of the rectangular magnetomotive force wave of figure 5 may be written as a Fourier series of the form

$$a = \sum \frac{A_q i_q}{m} \sin mky \cos m\gamma \tag{1}$$

where $m$ is the order of the space harmonic, and takes the values $2jq + 1$; $j = 0, 1, 2, 3, \ldots$ and $q$ is the number of phases. The values of $A_q$ for single-phase and balanced 3-phase windings are

$$A_1 = 8n \tag{1A}$$

$$A_3 = 12n \tag{1B}$$

The next step is to determine the flux density wave corresponding to each of the components of the magnetomotive-force wave such as

$$a_m = \frac{A_q i_q}{m} \sin mky \cos m\gamma \tag{2}$$

Let $B$ be the flux density in gausses at any point corresponding to the $m$th space harmonic of magnetomotive force, and let the subscripts $x$, $y$, and $z$ indicate the components of $B$ in the $x$, $y$, and $z$ directions. For the region

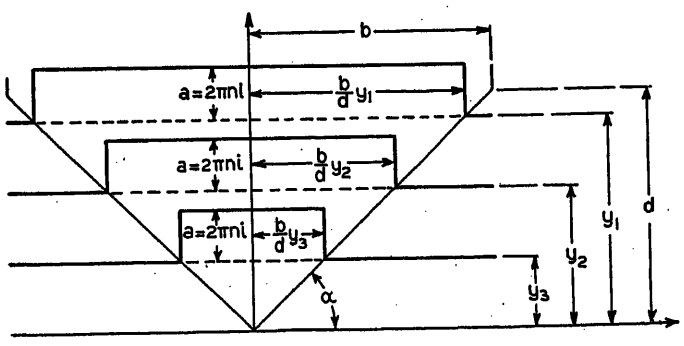

**Fig. 5. Diagram showing magnetomotive force wave for various values of y**

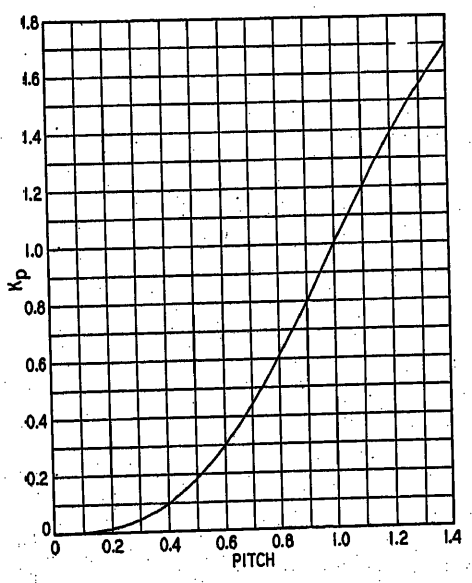

**Fig. 5A. Pitch factor**

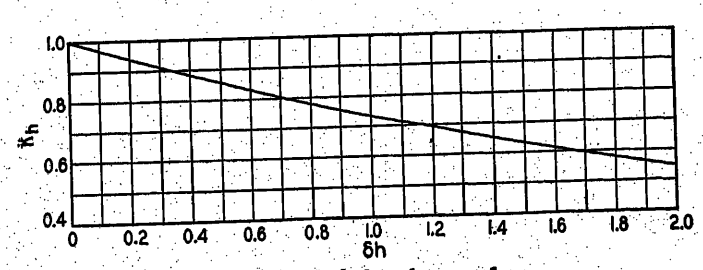

**Fig. 5B. Radial distribution factor**

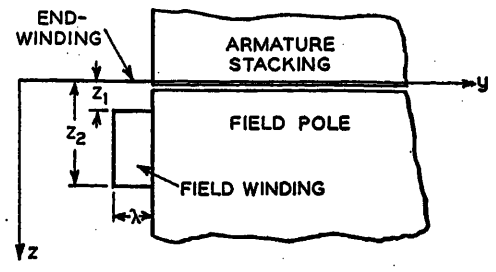

**Fig. 6. View of armature and field taken perpendicular to the plane of end - winding coils**

corresponding to positive values of $z$ in which there is assumed to be no magnetic medium and no current carrying conductors, the equations

$$\nabla . B = 0 \tag{3}$$

and

$$\nabla \times B = 0 \tag{4}$$

must be satisfied subject to the boundary conditions

$$\left.\begin{aligned} B_x &= -\frac{\partial a_m}{\partial x} \\ B_y &= -\frac{\partial a_m}{\partial y} \end{aligned}\right\} \text{When } z = 0 \tag{5, 6}$$

and

$$B \to 0 \text{ as } z \to \infty \tag{7}$$

The desired solution for positive values of $z$ is readily found by usual methods to be

$$B_z = B_m e^{-m\delta z} \sin mky \cos \frac{m\pi x}{D}, \tag{8}$$

where

$$\delta = \frac{P}{D} \csc\alpha \quad (9) \quad \text{and} \quad B_m = \delta A_q i_q \tag{10}$$

where $\alpha$ is the angle shown in figure 5.

The linkage $\psi_m$ in abampere-henries per phase per pole for the V-shaped end-winding which has $n$ conductors connected in series, is

$$\psi_m = n \int_0^d \int_{\frac{-b}{d}y}^{\frac{b}{d}y} \beta_m \, dx \, dy \times 10^{-9} \tag{11}$$

where $\beta_m = B_z$, when $z = 0$. Substitute the value of $\beta_m$ from equation 8 into equation 11, and integrate to obtain

$$\psi_m = \frac{\pi n D^2 \tan\alpha}{2mP^2} B_m K_{pm} \times 10^{-9} \tag{12}$$

where $K_{pm}$ is the pitch factor and is given by the equation

$$K_{pm} = p\left[1 - \frac{\sin mp\pi}{mp\pi}\right] \tag{13}$$

The inductance $L_m$ in henries corresponding to these linkages is

$$L_m = \frac{\psi_m}{iq} \tag{14}$$

where $i_q$ is the current in each of the $n$ conductors of the end winding. Substitute the values of $\Psi_m$ and $i_q$ into equation 14 to obtain the total inductance per pole per phase. The result is

$$L = \frac{\pi F_q n^2 D \sec \alpha}{P} \sum \frac{K_{pm}}{m} \times 10^{-9} \tag{15}$$

where

$$F_1 = 8 \tag{16}$$

and $m = 1, 3, 5\ldots$, for the single-phase case, and

$$F_3 = 12 \tag{17}$$

and $m = 1, 5, 7\ldots$, for the 3-phase case.

This derivation is based on the 6 assumptions previously listed. It is now necessary to develop corrections for these assumptions. First, consider the assumption that the phases are concentrated. In general the phases consist of several groups of conductors, each group of which occupies a different slot, and these slots are spaced around the periphery of the armature. The space waves of magnetomotive force due to these coils are out of phase by an angle determined by the angle between slots and the order of the space harmonic. Therefore the resultant magnetomotive force is less than for the case of concentrated phases, and the reduction factor $K_{dm}$ is applied to correct for this. Its value is given by the equation

$$K_{dm} = \frac{\sin m\frac{s\theta}{2}}{s \sin m\frac{\theta}{2}} \tag{18}$$

where $\theta$ is the angle measured in electrical radians between slots, and $s$ is the number of slots per pole per phase. Also the electromotive forces induced in the armature conductors by the rotating space waves of flux will be out of phase for the same reason, hence the reduction factor $K_{dm}$ must be applied again, or the total reduction factor is $K_{dm}^2$.

The factor, which applies to correct for the fact that the conductors have a dimension other than zero measured along the periphery of the armature, is equal to the ordinary distribution for a uniformly distributed phase which is distributed over the peripheral dimension $c$ of the rotor surface. Thus,

$$K_{cm} = \frac{\sin \frac{mPc}{2D}}{\frac{mPc}{2D}} \tag{19}$$

The derivation of this relation is based on the assumption that the current is uniformly distributed over the cross section of the conductor.

It should be noted at this point that the product $K_{dm}$ $K_{cm}$ is approximately equal to $C_m$, the distribution factor

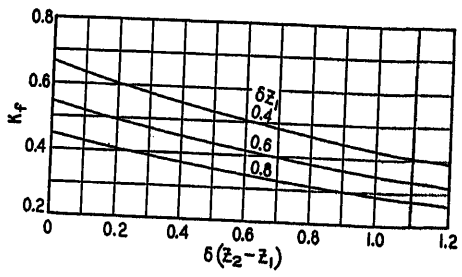

**Fig. 7A. Mutual inductance factor**

for a uniformly distributed winding, when spacing between the end-winding conductors is small as is usually the case. This is a good approximation particularly for the space fundamental.

The inductance is further reduced by the fact that the coil side has a depth or radial dimension $h$ which is greater than zero. The derivation of this reduction factor $K_{hm}$ is based on the result of equation 8 and the assumption of uniform current distribution over the coil side cross section. With the aid of equation 8 the flux density which is established at some point along $h$ by an infinite number of current filaments spaced equally along $h$ may be computed. Then the average of this flux density over the dimension $h$ divided by the flux density resulting from a concentrated conductor carrying the same current as the distributed conductor gives the desired reduction factor. The result is

$$K_{hm} = \frac{2}{m\delta h}\left(1 - \frac{1 - e^{-m\delta h}}{m\delta h}\right) \tag{20}$$

If

$$K_m = K_{pm} K_{dm}^2 K_{cm}^2 K_{hm} \tag{21}$$

then the formula for the end-winding inductance may be written as

$$L = \frac{\pi F_q n^2 D \sec \alpha}{P} \sum \frac{K_m}{m} \tag{22}$$

If the approximation $K_{dm}\, K_{cm} = C_m$ is made, then

$$K_m = K_{pm} C_m^2 K_{hm} = K_{pm} \frac{C_1^2}{m^2} K_{hm}' \tag{23}$$

and the end-winding inductance is

$$L = \frac{\pi F_q n^2 D \sec \alpha}{P} \sum \frac{K_{pm}\, C_1^2\, K_{hm}}{m^3} \tag{24}$$

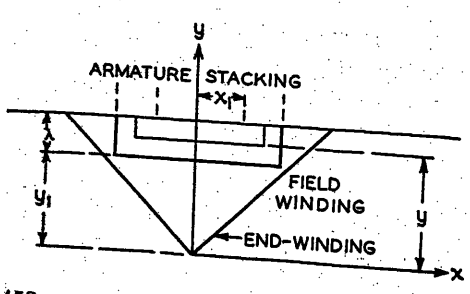

**Fig. 7. Development of end winding showing the field winding**

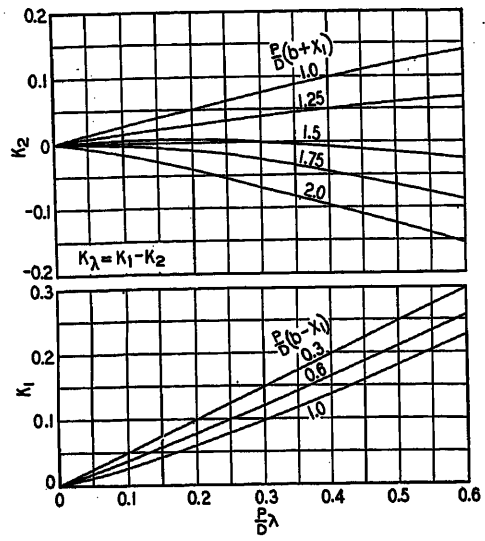

**Fig. 7B. Mutual inductance factor**

This series converges rapidly, and only the first term is necessary in computing for the usual case with the possible exception of the single-phase case where the third harmonic appears. In order to facilitate computation, curves of the factors $K_{pm}$ and $K_{hm}$ are given in figures 5*A* and 5*B*.

The assumption regarding the V shape of the end-winding coils is fairly close to the actual case except for that portion of the winding near to the armature core. However, the length of the conductor which extends straight out from the slot is usually small compared with the total length, and it seems that little error is introduced by this approximation.

The effect of the remaining assumptions has been investigated experimentally, and will be discussed later.

An important consideration, which has been completely ignored by previous writers, is the mutual linkage between the field coils and end winding. This is important; since, even though this mutual linkage may be a very small percentage of the total mutual linkage between the field and armature, it may be appreciable compared with the end-winding linkage thereby causing the end-winding *leakage* inductance to differ considerably from the total self-inductance of the end winding.

The field winding ordinarily extends an appreciable distance beyond the end of the field pole, hence this winding links some of the flux set up by the end winding. Figures 6 and 7 show a typical design for a salient-pole machine. According to assumption 4 none of the end-winding flux enters the field pole core, therefore, the only flux to be considered is that in the region occupied by the field winding which extends into the end-winding region.

The method to be employed in calculating this mutual linkage will be, first, to calculate the average component of flux perpendicular to the plane of the end winding over the radial depth and within the boundaries of the field coil by the use of equation 8. Next, it will be assumed that the field winding is uniformly distributed. Then the mutual linkage will be found by integration.

Select the same co-ordinate system as used in the derivation of equation 8 and as illustrated in figures 6 and 7.

Let the dimensions $z_1$, $z_2$, $x_1$, and $\lambda$ be measured in centimeters as shown in the diagram. Consider the case where the pole axis coincides with the phase axis, and the resulting mutual linkage will be the maximum value.

The average of $B_z$ from $z_1$ to $z_2$ as found from equation 8 is given by

$$B_z = B_m K_{fm} K_{dm} K_{cm} \sin mky \cos \frac{mPx}{D} \tag{25}$$

where

$$K_{fm} = \frac{1 - e^{-m\delta h}}{m\,\delta\,h} \frac{[1 - e^{-m\delta(z_2 - z_1)}]e^{-m\delta z_1}}{m\delta(z_2 - z_1)} \tag{26}$$

The corresponding linkage is found by integration. Thus the linkage $\Psi_m$ of the field coil due to the $m$th harmonic of the flux density wave set up by the field of the end winding is

$$\psi_m = \frac{D^2 n_f B_m K_{fm} K_{dm} K_{cm} K_{\lambda m} \times 10^{-9}}{m^2 P^2} \tag{27}$$

where $n_f$ is the number of turns per field pole, and

$$K_{\lambda m} = \frac{\sin \frac{mP}{D}(b - x_1)}{1 + \frac{b}{d}} + \frac{\sin \frac{mP}{D}(b + x_1)}{1 - \frac{b}{d}} + \frac{\cos \frac{mP}{D}(b - x_1) - \cos \frac{mP}{D}\left[b - x_1 - \left(1 + \frac{b}{D}\right)\lambda\right]}{\left(1 + \frac{b}{d}\right)^2 \frac{mP}{D}\lambda} - \frac{\cos \frac{mP}{D}(b + x_1) - \cos \frac{mP}{D}\left[b + x_1 + \left(1 - \frac{b}{d}\right)\lambda\right]}{\left(1 - \frac{b}{d}\right)^2 \frac{mP}{D}\lambda} \tag{28}$$

The corresponding mutual inductance in henries per pole per phase for both ends of the end winding is

$$M_0 = \frac{2F_q n n_f D \csc\alpha}{P} \sum \frac{K_{fm} C_1 K_{\lambda m}}{m^2} \times 10^{-9} \tag{29}$$

This is the maximum value of mutual inductance. In general only the first term of the series is required. The factors $K_{fm}$ and $K_{\lambda m}$ are rather complicated for computing purposes and they contain too many parameters to be given conveniently in the form of curves. However, if we neglect the effect of the term containing $h$ in the expression for $K_{fm}$ of equation 26, $K_{fm}$ may be conveniently given in curve form as shown on figure 7*A*. Likewise a constant value of $b/d = 0.577$ ($\alpha = 60$ degrees) is assumed in plotting the curves for $K_{\lambda m}$ as shown in figure 7*B*.

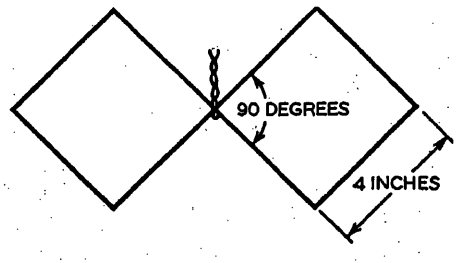

**Fig. 8. Sketch showing diamond-shaped coils used in mutual inductance measurement**

For a machine with a "sine wave winding"; that is, a machine which eliminates all effect on the terminal voltage of space harmonics of flux and magnetomotive

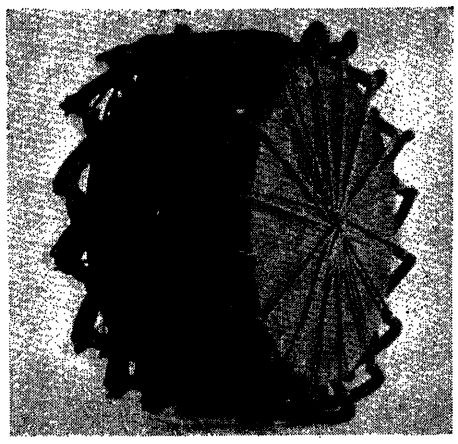

Fig. 9. End-winding model

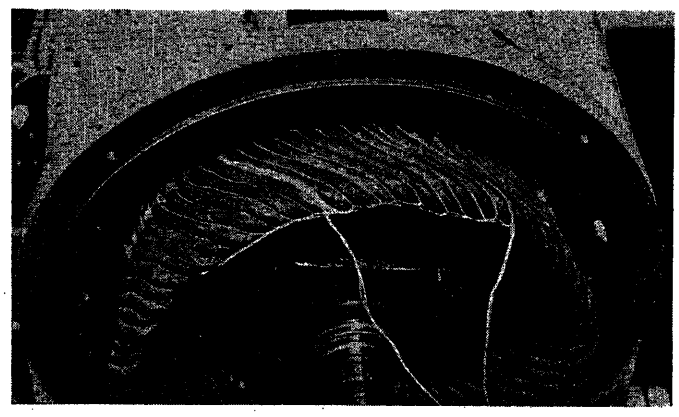

Fig. 10. View of exploring coils

force, this mutual inductance varies sinusoidally from its maximum value to zero as the pole moves through 90 electrical degrees. Blondel[5] first introduced the concept of expressing the armature inductance of such a machine by its values along the direct and quadrature axes, and most of the subsequent studies have employed this concept. It is desirable then to write the end-winding inductance along the direct or pole axis as

$$L_{ld} = L - \frac{n}{n_f} M_0 \qquad (30)$$

where $L$ is given by equation 22, and $M_0$ is given by equation 29.

## Experimental Techniques

Several experiments were performed to determine the accuracy of the assumptions. In so far as seemed feasible, the experiments were so arranged that each assumption was checked separately.

In order to determine the order of magnitude of the error introduced by the assumption that the end-winding conductors were produced as shown in figure 3, the mutual inductance of 2 diamond-shaped coils as shown in figure 8 was measured. With the 2 coils connected in series, the inductance differed by 1.5 per cent from the sum of the 2 self-inductances. The mutual inductance will of course vary with the shape and size of the coils, but its magnitude is negligible compared with the self-inductance, so the assumption appears reasonable.

An experimental check on the accuracy of formula 22 was obtained by measuring the inductance of models as shown in the photograph of figure 9 and comparing the result with the calculated value. The coils were connected as a single-phase 4-pole winding. The models were equipped with 4 coils per pole and each coil had 20 turns in series. The coil connections were arranged so that measurements could be made with 1, 2, 3, or 4 coils per pole.

This agreement is reasonably good; and since the model duplicated the actual end winding except for the effect of the iron in the armature stacking, these results indicate that the total error introduced by assumptions 1, 3, and 5 and the errors in the factors, which were developed to correct for assumptions 2 and 6, as previously listed is approximately ± 3 per cent.

The next experimental check consisted in measuring the inductance of the end winding of an actual machine. The tests were made on a 15-horsepower 220-volt 1,800-rpm 60-cycle 4-pole 3-phase salient-pole synchronous motor. The armature winding was reconnected single-phase.

Exploring coils were used to measure the inductance. They were placed on the end winding as shown in figure10 with a single turn of the exploring coil around each end-winding coil of a phase belt per pole. A 60-cycle voltage approximately sinusoidal in wave shape, was impressed on the armature circuit through an ammeter. The exploring coils were connected in series and the terminals were brought out to the input of a calibrated amplifier and voltmeter. The end-winding inductance was measured with the field axis and quadrature axis coinciding and with the field axis and the direct axis coinciding. Thus measurements were obtained for the conditions of maximum and minimum effect of the iron of the field stacking. The variation was found to be ±3.75 per cent from the average value.

The same arrangement was used in the measurement of the mutual inductance. In this case the field was

**Table I—Comparison of Calculated and Measured Values of Inductance of the Models as Shown in Figure 9**

| Coils per Pole | L in Millihenries: Calculated | Measured | Per Cent Error |
|---|---|---|---|
| **Model No. 1** | | | |
| 4 | 3.55 | 3.48 | 2.0 |
| 3 | 2.83 | 2.79 | 1.4 |
| 2 | 1.76 | 1.73 | 1.7 |
| 1 | 0.685 | 0.670 | 2.2 |
| Coil pitch = 1.0, single-phase, 4-pole, $D$ = 31 centimeters, $b$ = 12.2 centimeters, $d$ = 12.1 centimeters, $c$ = 1.34 centimeters, $h$ = 1.14 centimeters. | | | |
| **Model No. 2** | | | |
| 4 | 2.98 | 3.02 | 1.3 |
| 3 | 2.34 | 2.44 | 2.9 |
| 2 | 1.49 | 1.52 | 2.0 |
| 1 | 0.635 | 0.630 | 1.0 |
| Coil pitch = 0.75, single-phase, 4-pole, $D$ = 44 centimeters, $b$ = 12.95 centimeters, $d$ = 11.35 centimeters, $c$ = 1.34 centimeters, $h$ = 1.14 centimeters. | | | |

excited with a known current, while the machine was rotated at normal speed, and the voltage induced in the exploring coils was measured. Then

$$M_0 = \frac{E}{\omega I} \tag{32}$$

where $E$ is the maximum value of the exploring coil voltage in volts, $I$ is field current in amperes, and $\omega$ is the angular velocity in electrical radians per second.

A tabulation of the values of $M_o$ and $L_{la}$ as determined from test and calculation is shown in table II along with the value end-winding leakage as calculated from the formula given by Alger.[1]

## Conclusions

Let us consider now the effect of the primary assumptions previously tabulated. Accurate corrections have been developed for assumptions 2 and 6, and the probable error introduced by them is negligible.

The error introduced by assumption 3, regarding the continuation of the end-winding conductors beyond the apex of the V-shaped conductors, was determined by the measurement of the mutual inductance of 2 diamond-shaped coils. The error due to this assumption is approximately 1.5 per cent.

The errors introduced by assumptions 1 and 5 were evident in the measurement of the inductance of the end-winding model. The error due to assumption 3 was also included here, and the comparison of the calculated and measured value of inductance indicates an error of approximately ± 3 per cent.

The assumption that the component of the flux normal to the plane of the end of the armature core is zero is equivalent to assuming that none of the flux from the end-winding field enters the armature core. Since the ultimate aim of this study is to compute the end-winding *leakage* inductance, suppose that we assume instead that only the end-winding *leakage* field is unaffected by the iron of the armature stacking, and review the theoretical development on the basis of this assumption instead of the assumption that none of the flux from the end-winding field enters the armature core.

Physically the meaning of this assumption is apparent from a survey of the 2-dimensional sketch shown in figure 11. If there were no iron in the armature core the flux line at the boundary of the armature stacking would be vertical. Because of the iron the flux lines near the boundary are distorted as shown, but as the distance from the boundary increases the distortion due to the iron decreases, and this distortion of the field is apparently small beyond the boundary of the field pole winding; that is, the distortion is small in the region of the end-winding *leakage* field. It follows that this assumption is less radical than the assumption initially made, and only the simpler assumption is involved in the final result.

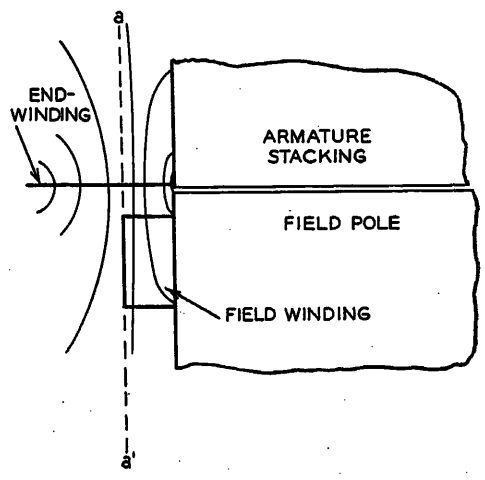

**Fig. 11. Sketch of end-winding field in a plane through the shaft axis and perpendicular to the plane of the end - winding coil**

It is believed that equation 30 is a step nearer to an accurate formula for the end-winding leakage inductance than any previously published. An effort has been made to indicate the nature and consequence of the assumptions involved and the effects of these assumptions have been investigated from an experimental viewpoint. An important part of the result is the expression for the flux density given by equation 8. This equation should serve as a basis for studying the effects of iron in the end-winding region. For example, the analysis may be extended to calculate the end-winding inductance of turbine generators where the rotor extends well into the end-winding region and to calculate the end-winding inductance of d-c machines where the conductors are supported by an iron ring.

# An Alternator-Voltage Regulator Utilizing a Nonlinear Circuit

By HARRY W. MAYNE

ALTHOUGH several different types of alternator-voltage regulators are in successful operation at present, the purpose of this paper is to describe a regulator which is believed to have several outstanding advantages over any of the present types. The inherent limitations of the various types of moving-contact regulators are well known, and a perusal of the circuit diagrams[1] of the different types of electronic regulators will indicate the complexity of such circuits, even though they are superior in most respects to the moving-contact-type regulators.

The regulator to be described here is of the electronic type, and is capable of the same degree of accuracy as the best of its type. It promises even faster operation than existing types and these characteristics are obtainable with a circuit utilizing 2 mercury-vapor control tubes combined with a small inductance, capacitance, and resistance.

## Nonlinear Circuits

The eccentricities of circuits containing capacitance and saturable core inductance have long been known to engineers. The particular phenomenon which first attracted attention was the so-called inversion or instability of the neutral of a 3-wire star-connected bank of transformers feeding a highly capacitive transmission line. Considerable material[2] was written on the peculiarities obtained, but it was not until 1931 that publications discussing simple single-phase circuits appeared.[3] Only the simple series circuit shown in figure 1 will be discussed. In figure 2 we have the effective volt-ampere characteristics of the circuit for various values of the resistance. From these curves we see that as the resistance is decreased, the slope of the curve increases so that it is possible to obtain a very large change in the effective value of the current with a negligible change in the effective value of the impressed voltage. Of course further reduction of the resistance produces a characteristic which is double-valued in current over a certain range of voltage, but these properties are of no utility in this particular application except as a limiting case.

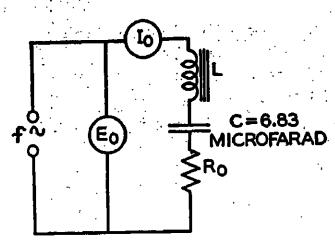

**Fig. 1. Nonlinear series circuit**

$R_0$ represents total d-c resistance of circuit

Because of the presence of the iron-cored coil, the wave form of the current in such a circuit is not sinusoidal, and is subject to considerable change as the effective value changes. Figure 3 is an enlarged drawing of superimposed oscillograms which illustrates the variation for the particular circuit used. Referring to figure 3, $I_1$ represents an effective value of 0.21 ampere, and the voltage required was 110 volts. When the voltage was increased to 111 volts, $I_2$, with an effective value of 0.43 ampere was obtained. The resistance in the circuit was 125 ohms, and the frequency 60 cycles per second. From the drawing we see that when the lower value of current is flowing, the crossing points of the current wave lag those of the voltage wave by approximately 20 degrees, and the peak current of 0.414 ampere occurs at 139 degrees. When the impressed voltage is increased from 110 to 111 volts effective value, or less than 1 per cent, the peak current increases to 0.908 amperes, or more than 100 per cent. In addition the wave is shifted so that the crossing points of the current wave are in the phase with those of the voltage wave. The peak current is also shifted by the same angle, approximately 20 degrees.

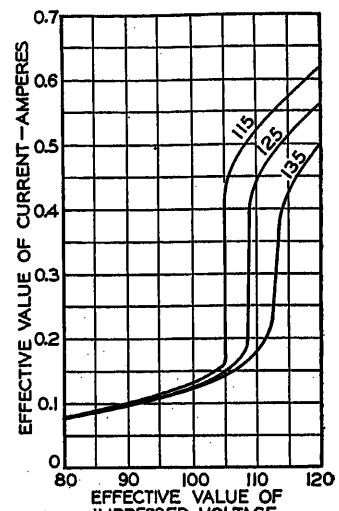

**Fig. 2. Effective volt-ampere characteristics for circuit of figure 1 at 60 cycles per second**

Numbers on curves are values of $R_0$ in ohms

## Application

With these general properties of the circuit in mind, the circuit shown in figure 4 was developed and tested. The alternator used was a 7.5-kva 60-cycle machine synchronously driven from a source having a frequency variation of ±0.3 cycle in 60. With a 7.5-kva load at

A paper awarded the 1935 AIEE South West District prize for best student Branch paper; recommended for publication by the AIEE committee on automatic stations. Manuscript submitted August 11, 1936; released for publication October 6, 1936.

0.85 power factor, the alternator regulation was 12 per cent and a 25 per cent decrease in field current was necessary to maintain normal voltage from full load to no load. The d-c end of a small a-c to d-c motor-generator set was used as a counter-electromotive-force generator in the alternator field circuit, and the drive was floated across the line to maintain constant speed. Type *FG-57* thyratrons were used as grid-controlled rectifiers supplying the counter-electromotive-force field. As these tubes are negative control tubes, it is necessary to use a d-c

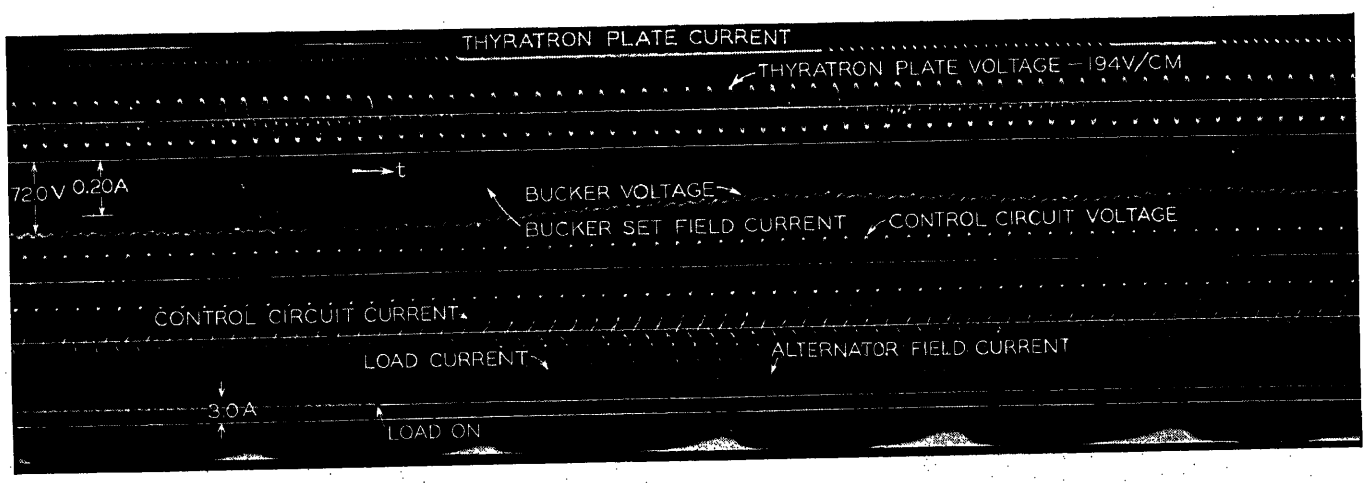

**Fig. 5a. Operation of regulator of figure 4 when load is applied**

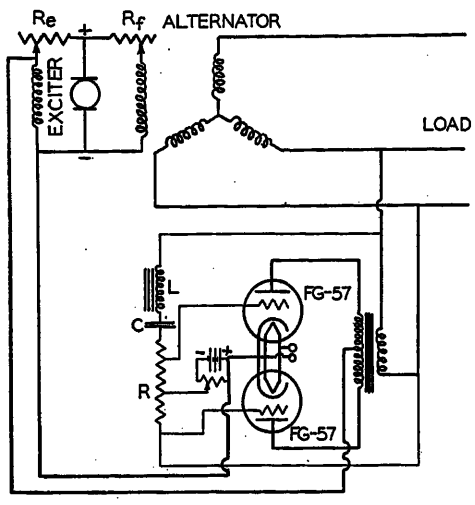

**Fig. 6. Circuit diagram of non-linear - circuit regulator operating on field of main exciter**

grid bias in addition to the a-c component. The use of the proper type of positive-grid-control tube would dispense with this grid battery.

The following preliminary adjustments are necessary to put the regulator in operation. The nonlinear circuit is adjusted so its characteristic is very steep at normal voltage on the alternator. With full load on the machine the field excitation is increased until the alternator voltage is just below the sensitive portion of the nonlinear circuit characteristic. The d-c grid bias on the rectifiers is then adjusted so the tubes are barely firing, and the field excitation further increased to provide the desired reserve capacity above full load.

After these adjustments have been made, suppose that the load is dropped suddenly. The terminal voltage will rise, producing a large rise in the nonlinear-circuit current, with the attendant phase shift referred to earlier. Since the circuit is connected so that the phase relation of the grid voltage to the thyratron plate voltage is the same as shown in figure 3, both changes produce a large increase in the average value of the rectifier plate current. This increases the terminal voltage of the counter-electromotive-force machine, with a corresponding decrease in alternator field excitation, thus tending to decrease the abnormally high alternator voltage. Any decrease, however, will react on the control circuit and tend to decrease the current again, so that the final equilibrium condition for no-load will be at a slightly higher voltage than at full load. With the machines used a regulator sensitivity of ± 0.2 per cent was obtained. The frequency variation of the source increased the variation to ± 0.3 per cent. The operation of the regulator is illustrated by the oscillograms shown in figures 5*a* and 5*b*. These show the variations when full load is applied and removed respec-

# Oxidation in Insulating Oil

By J. B. WHITEHEAD
FELLOW AIEE

F. E. MAURITZ
ENROLLED STUDENT AIEE

## I. Introduction

IT is generally agreed that of the component parts of impregnated paper, the impregnating oil is most susceptible to deterioration. There is, however little definite knowledge of the processes leading to instability. Instablility manifests itself in changes in electrical properties. An increase in dielectric loss, if allowed to continue, ultimately leads to failure. Marked chemical changes often accompany these changes in electric properties, but whether or not the changes are caused by electrical stress, as related to the inherent chemical structure of the oil, or by residual impurities, as related to stress and structure, or by both jointly is as yet unknown. Obviously oxidation, with its generation of acids and consequent increase in chemical dissociation and electrical conductivity is a powerful cause of instability. Although careful provision is made for the elimination of oxygen in the manufacture of insulation, it is recognized that traces of oxygen must remain under all circumstances, and the determination of the degree of its activity as a cause of insulation instability becomes a matter of great importance.

To the electrical engineer, the electrical stability of an oil is measured not in terms of the specific chemical changes that are taking place, but in changes in its electrical properties, i.e., its conductivity, dielectric loss, power factor, or phase difference, dielectric constant and breakdown strength. Extensive studies of the variations of these quantities over the life of impregnated insulation have been made, and a highly developed technique is available. Characteristic changes in the electrical properties, through the life of the insulation, are often traceable to changes in conductivity and ionic content,[1] and there are other conspicuous evidences of chemical changes. But as stated, there is still great uncertainty as to the original cause of these changes and of their subsequent progress. Many studies have been made of the process of oxidation in mineral and in other oils as used for insulation. It is a highly complex process involving many end products, as is natural in view of the complexity of the oil molecule itself. However, while much information is now available as to the process of oxidation and its various end products, there is little available material correlating the oxidation of an oil with its electrical properties.

In this paper we report a series of studies of accelerated oxidation in a highly refined insulating oil as used in oil-filled cables, with particular reference to the correlation between oxidation and electrical properties. For certain of these properties there is a marked correlation. The tests have been made at higher temperatures than normal for insulation, in order to accelerate the complete program. There are definite indications, however, that reliable deductions may be made for the behavior of the oil at lower temperatures and in the presence of smaller amounts of oxygen.

## II. Scope of Studies

The literature on oil oxidation often indicates erratic electrical correlation due to uncertainty as to the degree of the oxidation.[2] In studies of this character empirical methods have often been used,[3] as for example oxidation

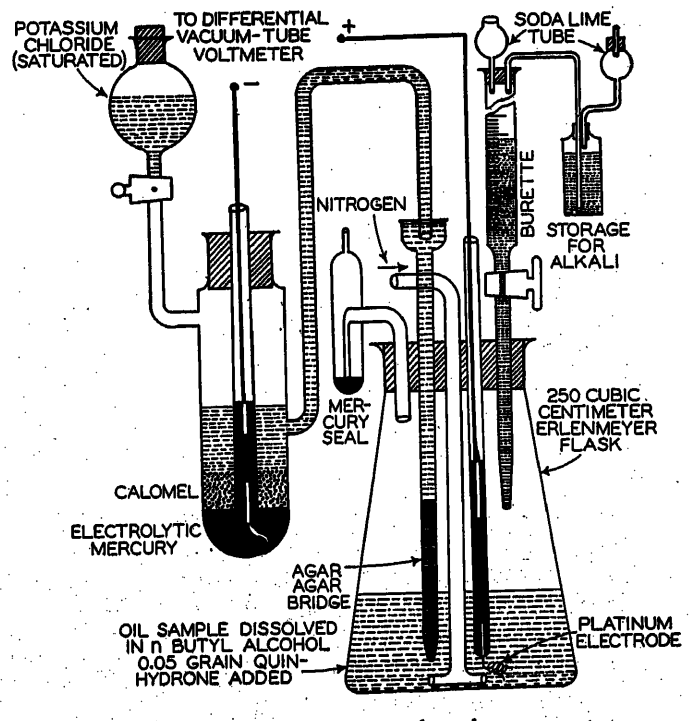

**Fig. 1. Schematic diagram of acidity apparatus**

is measured by the number of hours of heating in air or oxygen. Obviously more accurate methods are necessary.

The chemical quantities here measured are as follows: (*a*) the amount of oxygen chemically absorbed, the rate of absorption, and the reaction constant $k$, at the 3 temperatures 120, 135, and 150 degrees; (*b*) the activation energy as deduced from the results under (*a*); (*c*) acid number; (*d*) saponification number; and (*e*) carbon dioxide evolved; all as related to the amount of oxygen absorbed.

A paper recommended for publication by the AIEE committee on research. Manuscript submitted December 4, 1936; released for publication February 15, 1937.

J. B. WHITEHEAD is dean of the school of engineering of The Johns Hopkins University, Baltimore, Md.; F. E. MAURITZ is a former student at the university and now employed by the General Electric Company at Schenectady, N. Y., as a student engineer.

1. For all numbered references see list at end of paper.

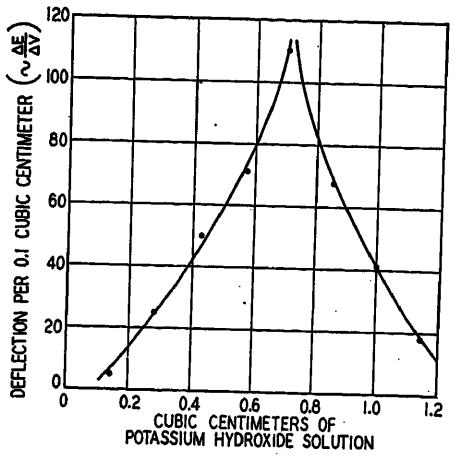

**Fig. 2. Typical titration curve**

The electrical quantities measured are: (*a*) power factor and a-c conductivity; (*b*) dielectric constant; (*c*) short-time d-c conductivity; (*d*) long-time d-c conductivity; (*e*) breakdown strength. Measurements of the electrical quantities were made for various values of acid number and through these related to the other chemical quantities referred to.

When an oil is oxidized acids are formed which dissociate and form new ions. An acidity determination defines the state of the oil in this respect without reference to its earlier history. We have found an excellent correlation between the acidity of an oil, the oxygen absorbed chemically, and certain of its electrical properties.

The saponification number gives an index of the acids combined in the oil which are capable of reacting with metals to form metallic soaps with consequent increases of conductivity and loss.

It has been shown[4] that of the gaseous products of oxidation of an oil, nearly 45 per cent is carbon dioxide. In this work measurements of the amount of carbon dioxide given off at various stages of oxidation show an interesting correlation with both acid number and electrical properties.

So far the studies here described have been made on only one oil. This was furnished by a well-known manufacturer and its properties are as follows:

| | |
|---|---|
| Base | refined light oil |
| Specific gravity at 45 degrees centigrade | 0.877 |
| Flash point, degrees centigrade | 149 |
| Pour point, degrees centigrade | −29 |
| Surface tension at 45 degrees centigrade | 27 |
| Viscosity, poises, at 45 degrees centigrade | 0.133 |
| Viscosity, poises, at 40 degrees centigrade | 0.160 |
| Breakdown volts | 27,500 |

## III. Experimental Method

### Oxygen Chemically Absorbed

Twenty cubic centimeters of the oil were placed in a 50-cubic-centimeter bulb and degasified at less than 1 millimeter mercury pressure. The oil was then saturated with oxygen by shaking for 5 minutes in an atmosphere of oxygen at atmospheric pressure. The bulb was then connected to a mercury burette filled with oxygen and then placed in a thermostat which maintained a constant temperature to within 0.1 degree Centigrade. The oxygen above the oil was maintained at atmospheric pressure. The bulb was then mechanically connected to a shaking machine and shaken at a constant speed of approximately 300 cycles per minute. Burette readings were then recorded as function of the time. This process was repeated for the 3 different temperatures 120, 135, and 150 degrees Centigrade. The oxygen absorption-versus-time curve thus obtained, is a straight line over a long period. The slope of this line, expressed in terms of cubic centimeters of oxygen chemically absorbed per 100 grams of oil per hour, is the reaction constant, *k*. This constant permits the determination of the activation energy of the oil as described below.

### Determination of the Acid Number

The acid number was determined with the method described by Clarke, Wooten, and Kompton.[5] The apparatus consists essentially of a titration cell and a reservoir for the storage of alkali, an electrode system, and a differential vacuum tube voltmeter. A schematic diagram is shown in figure 1. A second tube voltmeter was used to determine the total voltage of the electrode system at any stage of titration. The base electrode is a saturated calomel half-cell which made contact with the solution to be titrated through an agar agar bridge. The chemicals used in the calomel half-cell were specially prepared, and its voltage was 0.558 volt. The indicator electrode consisted of a bright platinum wire dipping into the solution to be examined. This solution consisted of approximately 8 grams of degasified and dehydrated oil dissolved

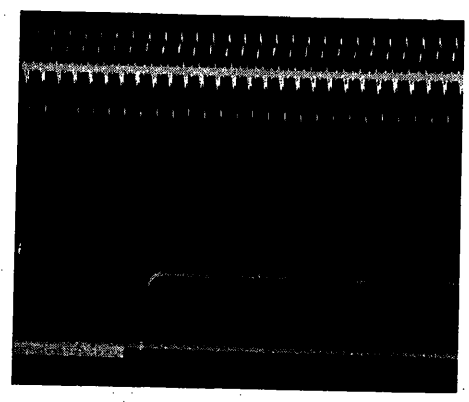

**Fig. 3. Charging current characteristics of undeteriorated oil**

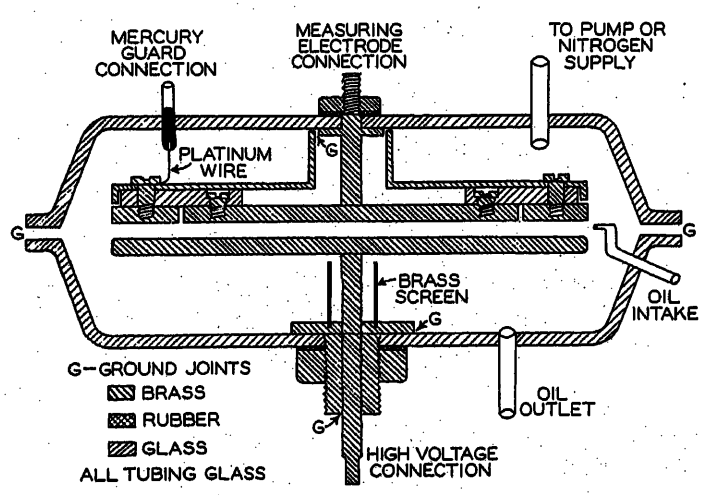
in 100 cubic centimeters of *n*-butyl alcohol to which 0.05 grams of quinhydrone had been added. All titrations were carried out in an atmosphere of nitrogen which served both to stir the solution and to exclude carbon dioxide which would lower the neutralizing value of the alkali. The technique of operation is as follows:

The differential voltmeter was first adjusted to read zero by varying a compensating resistor $R_2$. Known increments of alkali from the burette were added and corresponding deflections observed on a milliammeter. After every increment the differential voltmeter was compensated to zero milliammeter reading by adjusting $R_2$. These known equal increments of alkali were added up to, and after a maximum deflection was recorded. For accurate determinations the results are plotted as shown in figure 2, with deflection per 0.1 cubic centimeter as ordinates and total cubic centimeters of alkali added as abscissae. The maximum in this curve corresponds to the end point, that is the point where the slope of the voltage versus titer curve is a maximum. The apparatus as used here had a sensitivity for acid number better than 0.001.

Some observers report a double maximum in the curve of figure 2. This has been studied by Wooten and Reuhle[6] who show that it may appear when the alcoholic potassium hydroxide solution (titer) becomes deteriorated. Clear nonturbid solutions were used in this investigation and there was no occurrence of a second maximum. For the curve of figure 2, 0.715 cubic centimeter of 0.0387 *N* alcohol potassium hydroxide solution was necessary for neutralization of an 8.39-gram oil sample. Titration of the blank solvent had shown that less than 0.01 cubic centimeter of 0.0387 *N* alcohol potassium hydroxide was



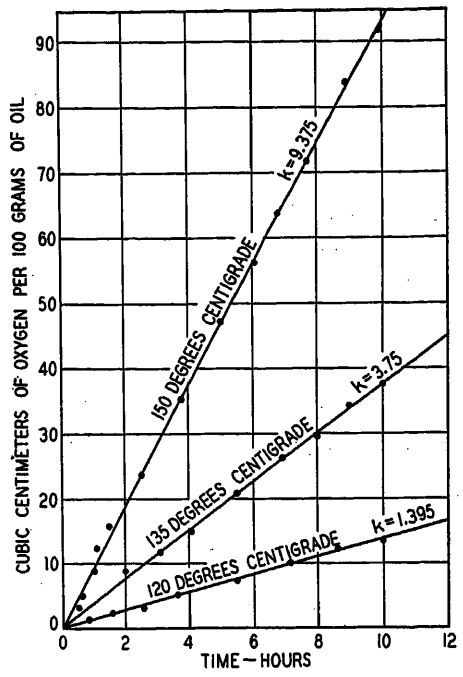


**Fig. 5. Oil cell for electrical measurements**

necessary for neutralization. The molecular weight of potassium hydroxide is 56.11. The acid number is then computed as follows:

$$\text{Acid number} = \frac{(0.715 - 0) \times 0.0387 \times 56.11}{8.39}$$

$$= 0.185 \text{ milligrams potassium hydroxide per gram of oil}$$

**Fig. 6. Oxygen absorption versus time**

### Saponification Number

When an oil is oxidized it may react with metals with which it is in contact to form metallic soaps of high conductivity which are usually soluble in the oil itself. A soap is defined as a metallic salt of a fatty acid. The saponification number is a measure of the amount of acids present capable of forming these soaps. Its determination consists essentially in the boiling of a known quantity of oil with a known quantity of potassium hydroxide. The excess potassium hydroxide not spent in neutralizing acids is then titrated with hydrochloric acid and serves as an index of the soaping value of the oil. The saponification number is expressed in terms of milligrams of potassium hydroxide per gram of oil. Determinations of saponification number in this work were made substantially in accordance with the specifications recommended by the American Society for Testing Materials.[7] Numbers observed were in the range 0 to 3.0 and duplicate determinations agreed within 0.1.

### Carbon Dioxide Given Off

The amount of carbon dioxide formed during the oxidation process was measured at different stages of the measurement of oxygen absorption by bringing the gas above the oil in contact with a potassium hydroxide solution. The difference of burette readings before and after this operation gives the amount of carbon dioxide formed.

### Electrical Measurements

The a-c quantities, power factor, a-c conductivity, dielectric constant, were measured on a shielded high sensitivity Schering bridge as described by Kouwenhoven and Baños.[8] The power factor sensitivity is 0.000006. Measurements were made at 60 cycles supplied from a generator having a pure sine wave. In all these measurements 2 determinations with exchange of the positions of the standard and the oil cells were made.

The a-c conductivity was computed from the dielectric loss and found to be in close agreement with direct measurements of the short time or initial conductivity as measured with the amplifier oscillograph.[9,10] Whitehead[11] has shown that the initial d-c conductivity and the

a-c conductivity of an oil are identical when no polar element is present. Figures 3 and 4 give the oscillograms of the charging currents of the oil in its initial and in its most highly oxidized condition respectively. These curves and the agreement between measured and computed losses indicate the absence of heavy polar aggregates both before and after oxidation.

The long-time d-c conductivity which is approximately constant after 20 minutes of application of voltage was measured with a high sensitivity d'Arsonval galvanometer.

Breakdown measurements were made in accordance with ASTM specifications[12] using a commercial breakdown cup. In all cases the oil was degasified and dehydrated before being placed in the cup. The spread of breakdown values was well within those called for by ASTM specifications.

### Oil Test Cell

The test cell for the electrical measurements consisted essentially of a circular parallel plate capacitor equipped with guard rings as indicated in figure 5. The electrodes were of polished brass. The measuring electrode had a diameter of 13.0 centimeters surrounded by a guard ring 2.54 centimeters wide, with an air gap of 0.16 centimeters. Glass insulation and screening is indicated in figure 5. The capacitance of the cell when empty was 77 micromicrofarads and when full approximately 177 micromicrofarads. The measurements were made at 60 cycles and a stress of 25 volts per mil with electrode separation of 0.152 centimeter.

The electrodes were supported one each in 2 similar glass containers, one of which was inverted, placed on the other with ground surfaces of contact as indicated. The lower container supported the high voltage electrode with a cylindrical screw guard rigidly attached. The top member was coated with tin foil and maintained at guard potential to prevent leakage currents entering the measuring circuit. The test cell held approximately 1,000 cubic centimeters of oil and was so connected as to permit vacuum intake during measurements. The whole cell was enclosed in a thermally insulated box with temperature controlled by thermostat to within 0.2 degrees centigrade and with provision for constant air circulation within the box.

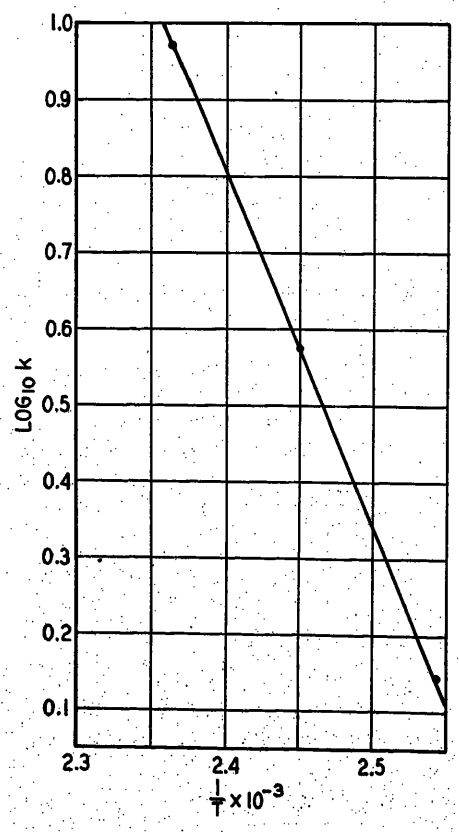

**Fig. 7. $\text{Log}_{10}$ k versus 1/T**

Q = 20,700 calories per mol

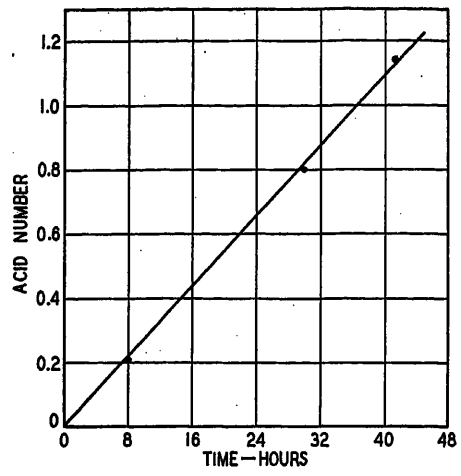

**Fig. 8. Acid number versus time**

Oxidizing temperature—150 degrees centigrade

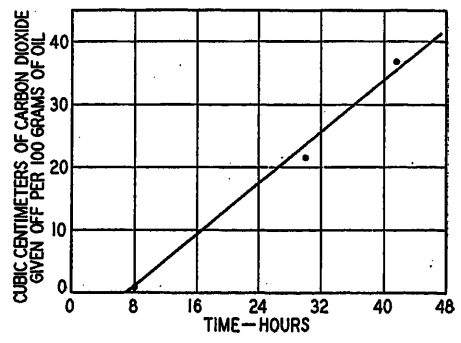

**Fig. 9. Carbon dioxide given off versus time**

Oxidizing temperature—150 degrees centigrade

The oils used in the electrical measurements were oxidized by heating in air at 125 degrees centigrade to various selected values of acidity. Before admission to the test cell each oil sample was given standard evacuation treatment for the purpose of degasifying and dehydrating. This was accomplished by heating the oil to 80 degrees centigrade and admitting slowly into a vacuum of less than 1 millimeter mercury pressure. Thus any water formed during the oxidation process was eliminated before the electrical measurements. The oil was then drawn into the measuring cell without contact with air. Dry nitrogen was then admitted over the oil and maintained at a small positive pressure.

## IV. Experimental Results

The principal experimental results are shown in figures 3 and 4, and figures 6 to 23.

### Chemical Properties

Figure 6 shows the relation between oxygen chemically absorbed and time at each of the 3 temperatures 120, 135, and 150 degrees Centigrade. The ordinates are cubic centimeters of oxygen per 100 grams of oil, and the abscissae, the time in hours. The slope of each of these straight lines is the reaction constant $k$ and is expressed arbi-

trarily in terms of cubic centimeters of oxygen per 100 grams of oil per hour. It will be noted that there is a strictly linear relationship with definite value of $k$ at each temperature. Beginning at zero on the time scale, there is thus no induction period or lagging time of the oxygen reaction. Such lag is often noted at lower temperatures. Thus in the present case lags of 12, 27, and 49 hours were

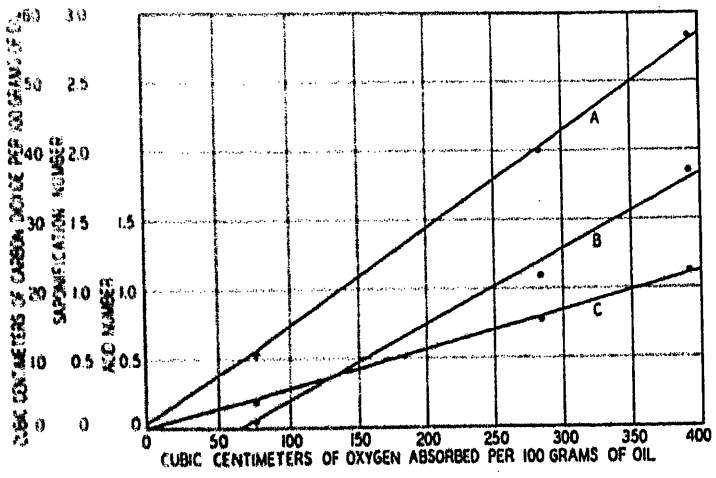

**Fig. 10. Acid number, saponification number, and carbon dioxide given off versus oxygen absorption**

Oxidizing temperature—150 degrees centigrade
*A*—Saponification number
*B*—Carbon dioxide
*C*—Acid number

noted at the temperatures 100, 90, and 80 degrees, respectively.

It is necessary for a molecule to be activated before chemical reaction can begin. For this a minimum quantity of energy is necessary. In the present case this energy, in the form of heat, was found to be constant over the range studied. Thus a determination of the amount of this heat appears to be a good criterion as to the susceptibility of the oil to the oxygen reaction. The activation energy $Q$ may be determined from the data of figure 6 by the use of the Arrhenius equation:

$$\frac{d \log k}{dT} = \frac{Q}{RT^2}$$

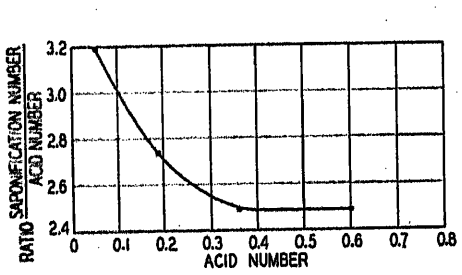
in which $T$ is the absolute temperature, $Q$ the activation energy in calories per mol, $R$ the gas constant, and $k$, the reaction constant. On integration of the equation we have:

$$\log_{10} k = c_1 - \frac{Q}{4.58} \times \frac{1}{T}$$

whence $Q$ may be determined graphically by plotting $\log_{10} k$ as function of $1/T$, as shown in figure 7. While only 3 points are available for this curve, corresponding to the 3 temperatures studied, it is seen that they lie accurately on a straight line indicating a constant value of 20,700 calories per mol for $Q$ within this range, with no evidence of a change in slope such as might be caused by molecular disruption or cracking as sometimes proposed.[13] There is clear suggestion here that the activation energy of this oil is constant, at least up to the temperature of 150 degrees.

Figure 8 shows a linear relationship between acid number and time in hours of heating at 150 degrees centigrade, and figure 9 shows a linear relation between the carbon dioxide given off and time of oxidizing at 150 degrees centigrade. In figure 10 the observations of acid number, carbon dioxide, and saponification number are shown together as related to the amount of oxygen absorbed per 100 grams of oil. In obtaining these data 3 samples were drawn for acidity determinations at 8, 30 and 41.8 hours respectively of the continuous oxidation run. The saponification data were taken on a separate run with simultaneous observation of acid number.

In figure 11 the ratio of saponification number to acid number is plotted as function of acid number. It is seen that in the initial stages of oxidation, there are relatively few free acid ions as compared with the acids combined in the oil. On further oxidation the ratio of these 2 concentrations approaches a constant value.



## Electrical Properties

The correlation between chemical and electrical properties is shown in table I, from which the following curves have been plotted.

Figure 12 indicates a definitely linear relationship between power factor as measured at 40 degrees Centigrade and the acid number. Figure 13 shows a similar relation between power factor and saponification number.

Figures 14 and 15 show the variation of dielectric constant with acid number and saponification number, respectively. As seen, these curves are slightly concave upward and indicate an over-all increase of nearly 5 per cent in

**Fig. 11. Ratio (saponification number / acid number) versus acid number**

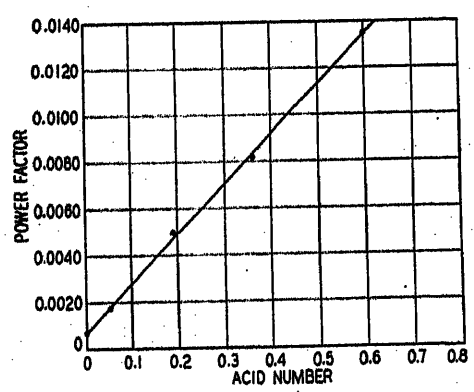


**Fig. 12. Power factor versus acid number at 40 degrees centigrade**

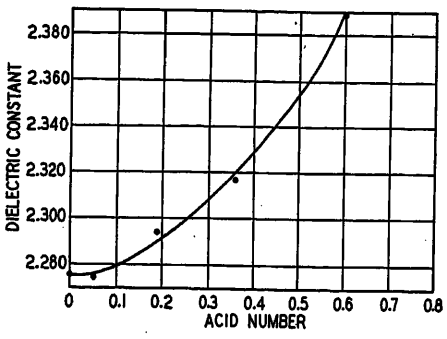

**Fig. 14. Dielectric constant versus acid number at 40 degrees centigrade**

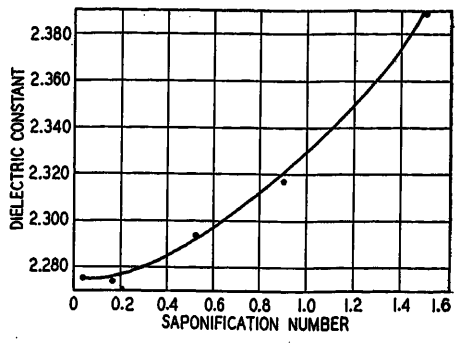

**Fig. 15. Dielectric constant versus saponification number at 40 degrees centigrade**

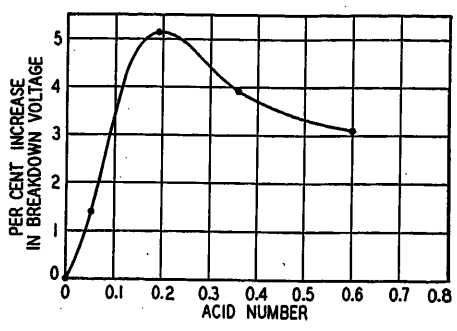

**Fig. 16. Per cent increase in breakdown voltage versus acid number**

Initial breakdown voltage 27,500 volts

dielectric constant over the range 0.0 to 0.6 for acid number.

Figures 16 and 17 show the relationship between breakdown voltage and acid number and saponification number, respectively. It is interesting to note that on initial oxidation, the breakdown strength of the oil increased approximately 5 per cent, and upon further oxidation only a moderate decrease toward the initial value is indicated over a considerable range of oxidation.

Figures 18 and 19 show the variation of final or long-time d-c conductivity with acid number and saponification number, respectively. Final conductivity is seen to vary from $0.2 \times 10^{-15}$ to $154 \times 10^{-15}$ mhos per centimeter over the range studied, an increase of some 750 times.

Figure 18 also shows a curve of computed final conductivity due to free acids. For the purpose of computation, the oil is assumed to have one representative acid having a molecular weight of 150 (Herzfeld[14]) and 2 replaceable hydrogen atoms per molecule. The neutralizing process with potassium hydroxide provides a relation between acid number and concentration of acids in grams per liter of oil. Then using the dissociation constant given by Gemant[15] and the method of the latter, taking due account of viscosity, the value of the final conductivity may be computed. As shown in figure 18 the value so found is of the order of $^1/_{12}$ of the measured conductivity which would seem to suggest some other cause of conductivity than the presence of acid ions. While the figure of 150 for the molecular weight proposed by Herzfeld is quite high the conductivity varies only inversely as the square root of the molecular weight and a substantial reduction in the figure used would still leave a large part of the conductivity unaccounted for.

Figures 20 and 21 show the ratio of the a-c or initial conductivity to the final conductivity as function of acid number and saponification number, respectively. These curves are especially interesting as showing the influence of the oxidation products on the conductivity. For the oil in its initial state, with the acid and saponification numbers practically zero, the ratio of a-c to final conduc-

Dielectric loss computed at 1,500 volts.
* Expressed in milligrams of potassium hydroxide per gram of oil.

tivity is approximately 247. This ratio decreases rapidly with oxidation and seems to approach a final value. At an acid number of 0.605, the ratio is 7.05. This is in accord with the observations of Whitehead and coworkers[16] that increasing final conductivity is accompanied by a reduction in the value of this ratio.

In figures 22 and 23 the dielectric loss, as computed from the bridge measurement is plotted as function of acid number and saponification number, respectively. The losses were measured at 40 degrees centigrade, 60 cycles and a stress of 25 volts per mil. Values of a-c conductivity computed from the dielectric loss measurements and the initial or short time conductivity, as measured by the amplifier oscillograph were in close agreement, as shown in table 1. The dielectric loss at constant stress varies in linear relation with the acid number following the corresponding variation of the power factor. The variation of dielectric constant with acid number, shown in figure 14 is too small in over-all value to cause an appreciable variation of the dielectric loss from that of its linear relation with acid number.

## V. Discussion

### The Oxidation Process

The linear relation between oxygen chemically absorbed and time, shown in figure 6 indicates that the products of oxidation in the range studied do not act as catalysts for further oxidation. Dornte[17] and Egerton[18] report a "self acceleration" for certain oils, i.e., the products of initial reaction augment further reaction. There is no evidence of such action here.

At low oxidation temperatures there is an initial period at which there is negligible and unstable absorption of

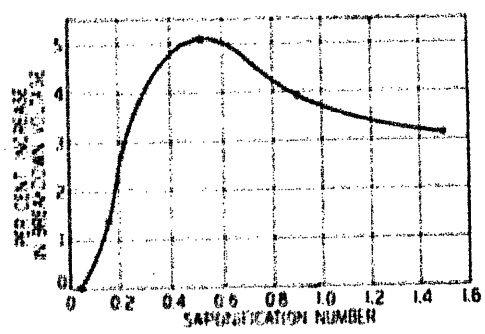

**Fig. 17. Per cent increase in breakdown voltage versus saponification number**

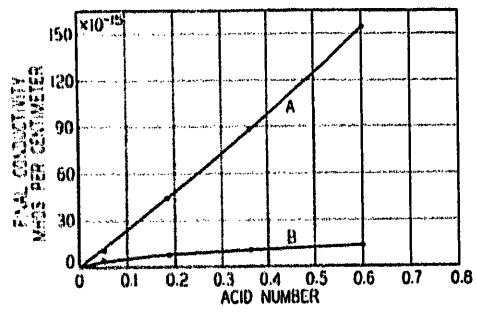

Initial breakdown voltage 27,500 volts

oxygen by the oil. The oil will absorb and then give off oxygen of varying quantities. The duration of this condition is called the "induction period" and its length decreases rapidly with temperature elevation. There is difference of opinion as to the cause of the induction period. Some hold that it is a property of oxidizability of the molecules, others that it is due to impurities in the oil which may act positively or negatively in retarding oxidation. The so-called antioxidants serve to prolong the induction period, whereas a catalyst such as copper shortens it. However, once the reaction begins, the oxygen absorption versus time curves appear to obey the same law, as shown here, and also by Egerton[18] in studies of the same oil (*a*) alone, (*b*) in the presence of copper, and (*c*) when containing an antioxidant. Similar conclusions are to be had from the work of Dornte.[17,19]

The linear relations shown in figure 10 indicate that at 150 degrees for the oil studied there is no induction period in the uniform rise of the values of acid number and saponification number with oxygen absorbed. There is, however, a lag or induction period for carbon dioxide evolved of about 6½ hours. Uniform rises of both acid number and saponification number within this period indicate that the processes leading to the appearance of carbon dioxide also begin uniformly, so continue through the induction period, and on into the actual evolution of

**Fig. 18. Final conductivity versus acid number at 40 degrees centigrade**

*A*—Measured
*B*—Computed conductivity due to free acids

carbon dioxide. In other words, the process is continuous although it may not be immediately evident.

The activation energy is constant over the range 120 to 150 degrees. A part of this energy is obviously expended in the hidden processes of the induction period of carbon dioxide. The 6½ hours of this period measured at 150 degrees is presumably longer at 120 degrees, yet the activation energy is constant over this range. Thus it seems reasonable to conclude that the straight line relation of figure 7 (constant $Q$) may be extended to lower temperatures and that the activation energy is constant in the lower temperature range and at the value determined in the upper temperature range. The activation energy so determined thus appears as a definite measure of the rate of chemical absorption of oxygen or of oxidizability. A sharp change in the slope of the curve of figure 7 would indicate a critical temperature, marking a change in oxidation process. The existence of such a critical temperature at about 120 degrees is proposed by Gemant[13] and others. Karapetoff[20] finds no evidence of such critical temperatures in the work from American laboratories. Dornte[19] in experiments up to 185 degrees Centigrade finds no evidence of a "cracking temperature." Oxidation in insulating oils has long been recognized as a chain process. Dornte [17,19] studying 2 groups of oils found different laws for the 2 groups, but noted that the amounts of each product of oxidation formed over a period of time obeyed the same law as that which applied to the oxygen absorption indicating oxidation as a chain or step-by-step process.

Unfortunately a determination of the value of $Q$ requires much time and is subject to considerable error. The values of $k$, from which those of $Q$ are obtained, may vary in different samples as much as 10 per cent. Thus the

final value of $Q$ found in the present instance is 20,700 calories per mol, with a possible error of about 1,000 calories per mol. The value itself is apparently somewhat low, values as high as 45,000 for oils having been reported by other workers.

Using the value of $Q$ as given above and its relation with $k$ simple computation shows that at 45 degrees Centigrade, the value of $k$ would be 0.0028 and that for saturation

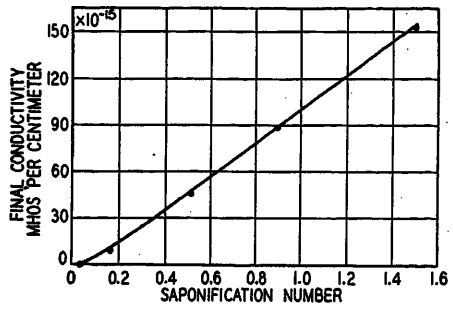

**Fig. 19. Final conductivity versus saponification number at 40 degrees centigrade**

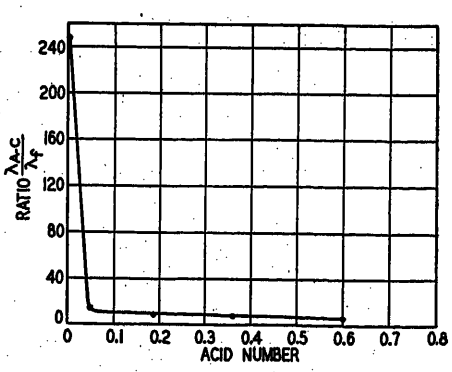
with oxygen this oil would require an induction period of 4 3/4 days. Thirty days after expiration of the induction period, the oil would have absorbed chemically 0.141 cubic centimeters of oxygen per gram of oil. This would cause a change in acid number of 0.0402 or a change in power factor of 0.00086. From these figures, it will be evident that for studies of this character an accelerated program at higher temperatures is imperative.



As regards the saponification number and the curve of figure 11 it is apparent that in the initial stages of oxidation there are proportionally more acids combined in the oil capable of forming metallic soaps than there are free acids. This curve as well as the quiescent period for carbon dioxide suggests that the initial oxidation of the oil up to acid number of about 0.2, while increasing acid content uniformly, also has a transient element serving to convert the oil from one oxidation state to another.

## Electrical Properties

Of outstanding interest is the linear relation between acid number and power factor or dielectric loss. The initial or a-c conductivity of an oil is very much larger than the d-c conductivity measured after a long period of application of voltage. There is some evidence[21] that the ions involved in the 2 cases have different origins and perhaps different character. The difference between the 2 types is found only in purer and more highly refined liquids. With increasing impurities or deterioration such as oxidation in an oil, the difference between the 2 conductivities disappears and the ratio of initial to final conductivity approaches unity and the number of ions involved in the initial conductivity is submerged ultimately in those due to the oxidation or other cause. The transfer from the initial pure to a more deteriorated condition is clearly shown in figure 20. It is of interest to note, however, that the range of acid number for which the ions of the initial conductivity play an important part is relatively low. Their contribution to conductivity and power factor, is appreciable in the region of zero acid number, and causes the initial power factor of the oil. However they soon become relatively unimportant with increasing oxidation, nor do they at any point partake of an acid character. Various causes have been suggested for the origin of the ions causing the initial conductivity; as for example, ionic impurities of nonacid character, the liberation of electrons from the electrodes, internal liquid ionization by radio active or cosmic influence. The rate of generation of ions by the latter causes is quite low but over a period of time they accumulate in numbers up to an equilibrium condition, as related to the rates of recombination and diffusion to the walls of the container. They may be swept out temporarily by high continuous voltage, but on open circuit increase again slowly to their original number.[21] From the results of the present work, it is apparent that in the case of a highly refined oil, study of the correlation between the change in electrical properties and oxidation should take due account of the ions already present as shown in the short time conductivity, and of those due to oxidation, especially in the early stages. For later stages of oxidation, however, the initial conductivity plays no appreciable part.

The increase of dielectric constant with acid number as shown in figure 14 is apparently due to the presence of polar molecules, the polar property being well known for the oxidation products of hydrocarbons. The presence of polar aggregates much larger than molecules has been noted by Whitehead, but these larger aggregates are apparently absent in the present case for they are not evident in the short time d-c conductivity oscillograms, nor is there any measurable increase in the dielectric loss due to this cause. The variation in density over the most extended range of oxidation was less than 0.5 per cent indicating that the increase in dielectric constant is not

**Fig. 20. Ratio (a-c conductivity/final conductivity) versus acid number at 40 degrees centigrade**

due in any appreciable measure to increase of atomic polarization.

In the matter of breakdown the transitory period in the oxidation process, involving as it does the molecular structure of the oil, seems to play a part. The breakdown strength increases, due perhaps to the oxidation or clean-up of residual impurities or the break-up of large unstable molecules with loosely connected valence bonds into smaller and more stable molecules. The subsequent de-

crease is apparently due to increased conductivity (Nikuradse[22]).

Considering then oxidation in its influence on the insulating properties of oils, we note 2 notoriously dangerous results, namely, increasing power factor and the evolution of gas. Increasing power factor means increasing dielectric loss and reduction of carrying capacity, and if the increase continues unabated, it leads definitely in the direction of failure. The evolution of gas means gaseous ionization with its well-known rapid destructive influence on fibrous impregnated insulation.

In the oil here studied we have shown a definite linear relation between the oxygen absorbed and the increase in power factor on the one hand, and the amount of gas evolved on the other. Consequently, for oil of this type it is clear that measurements of power factor and gas evolution, as related to oxygen absorbed, should constitute a reliable basis for the comparison of the oxidation stability of different oils. Moreover both measurements are important. At a recent meeting of the committee on electrical insulation, division of engineering and industrial research, National Research Council, R. W. Dornte divides oils into 3 classes as regards the rate with which they absorb oxygen in chemical combination. The oil studied in this paper falls in class (2), showing a rate of absorption directly proportional to the time. Several

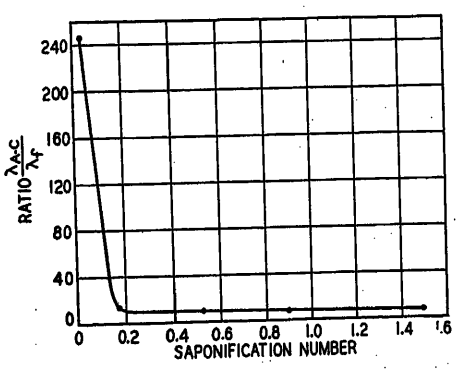


**Fig. 21. Ratio (a-c conductivity/final conductivity) versus saponification number at 40 degrees centigrade**

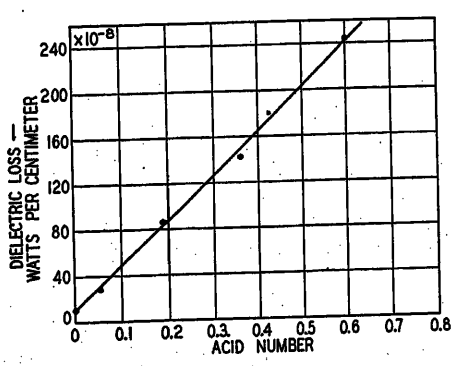

**Fig. 22. Dielectric loss versus acid number at 40 degrees centigrade**

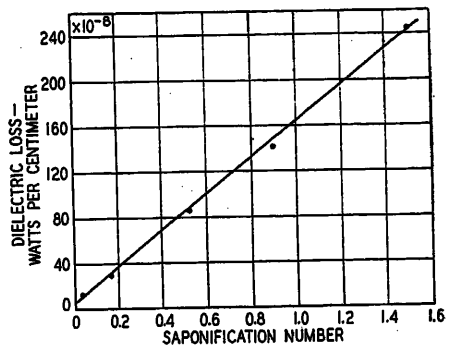
$E$ = 1,500 volts

other papers presented at the same meeting indicated, however, that the oxidation products of various types of oil are proportional to the amount of oxygen and not to the reaction constant $k$ which is a measure of the rate of oxygen absorption. Consequently it appears probable that the above correlations found in the single oil here studied will also be found in other oils.



## VI. Conclusions

1. Accelerated oxidation studies have been made on a typical high-grade insulating oil. Linear relations are found over a wide range between the amount of oxygen chemically absorbed and time, acid number, saponification number, and carbon dioxide evolved.

2. Two periods of oxidation are indicated for the oil studied: (*a*) an initial transient period in which intermediate products are formed, (*b*) a subsequent period in which further oxidation does not materially add to the intermediate products, but increases the amount of the end products.

**Fig. 23. Dielectric loss versus saponification number at 40 degrees centigrade**

$E$ = 1,500 volts

3. Similar linear relations have been found between the oxygen absorbed and power factor, dielectric loss, and long time d-c conductivities as measured at 40 degrees centigrade. The ratio of initial or a-c conductivity to final conductivity rapidly decreases with increasing oxidation in its early stages, thereafter much more slowly, indicating different natures for the a-c conductivities of refined and oxidized oils.

4. A relatively small, but apparently characteristic change in dielectric constant with increasing oxidation is due to the polar properties of the oxidation products.

5. With increasing oxidation the breakdown strength at first increases by about 5 per cent, passes through a maximum at about 0.2 acid number, and decreases again. These changes occur in the transient range of the oxidation processes.

6. The linear relation between oxygen absorbed and time leads to definite values of the reaction constant $k$, and to a constant value of the activation energy $Q$. Evidence is presented that the values of these quantities, obtained at higher temperatures, are reliable as good indices of the electrical behavior of the oil as related to oxygen absorption, at lower temperatures.

7. Evidence is presented indicating that the linear correlations found between oxygen absorption, gas evolved, and power factor increase in accelerated oxidation studies provide a reliable basis for estimating the relative oxidation stabilities of insulating oils.

## Voltage Drop and Load Balance in Open-Y Circuit

(*Continued from page 437*)

feet will be about 1.2 volts and for the lagging phase about 3.2 volts. For a 500,000-circular-mil conductor, assuming the same conditions as for number 8, the voltage drop for the leading phase will be about 2 volts, and for the lagging phase about 1.25 volts.

As indicated by these curves the dashed lines are obtained by the difference in the voltage drop between the leading and lagging phases. At the point where each dashed line crosses the abscissa the difference in voltage drop between the leading and lagging phases is zero, hence the voltage drop is the same on both phases for the indicated amount of unbalancing and the indicated power factor. As shown by the curves for a number 8 conductor and a power factor of 0.9, the leading phase should carry about 60 per cent and the lagging phase about 40 per cent of the load. For a 500,000-circular-mil conductor and a power factor of 0.9, conditions are reversed and the dashed line crosses the abscissa at the point where the leading phase should carry about 40 per cent and the lagging phase about 60 per cent of the load.

Figure 4*A* condenses information about the proper load division between phases at various power factors in order to obtain balanced voltage conditions at the load.

These curves are very useful in determining the correct load balance between the leading and lagging phases in a building where the old d-c wiring is to be used. In such a case, the total load to be carried, the power factor, and the size of the conductors are fixed and the only variable will be the load balance between the 2 phases. The correct load balance can be determined specifically from the curves of figure 4*A*.

It will be noted that these curves have been derived for conditions where the power factors are the same on both phases. An infinite number of other conditions may arise in which the power factors will be different on the 2 phases. If a sufficiently large number of cases occur where certain definite power factors exist, curves of voltage drops for these conditions can, of course, be drawn.

## Power System Faults to Ground

(*Continued from page 433*)

voltage per foot of arc length is practically independent of current magnitude and ranges between about 200 and 400 root-mean-square volts per foot of arc. The results offer a method of estimating, during the first few cycles of an arc, that portion of the fault resistance in the arc. For longer durations of fault, such estimates are likely to be inaccurate unless some idea of the length of extension of the arc can be secured.

(*d*) For steel tower lines carrying ground wires, tower footing resistance will have little effect on fault current magnitude if $l$, the length in miles of the section of line involved, is greater than

$$5\left(\frac{\sqrt{\text{average tower footing resistance}}}{\text{number of towers per mile}}\right)$$

In the case of steel tower lines with high-conductivity ground wires, it seems apparent that arc resistance and tower footing resistance alone will not account for apparent fault resistances of the magnitudes given earlier, indicating that factors other than these are involved.

## A New Magnetic Flux Meter

(*Continued from page 445*)

by means of calibration curves. Another slight disadvantage is that for all readings the current supplied to the bridge must be maintained constant.

The question naturally arises as to whether the bridge can be used for alternating or rapidly varying magnetic fields. Tests made during this research prove that readings are obtained as readily in alternating fields as in stationary fields, but no calibrations have been attempted as yet because of lack of apparatus and time. The reports of previous research [10,11,12] appear to indicate a lag in the change of resistance of the bismuth, though it may not be serious enough appreciably to effect the accuracy of the bridge at low frequencies, perhaps even up to 60 cycles. Further research in the use of the bridge for the alternating flux field appears to be highly desirable.

(*Continued from page 464*)

tively. Inspection indicates that operation is completed in 15 to 20 cycles after the disturbance, and that this delay is largely due to the time constants of the machines used rather than the control circuit, which effects the maximum possible change in the rectifier plate current in less than 5 cycles after the disturbance. By its nature, the arrangement is well damped, and no auxiliary circuit was necessary to prevent or reduce hunting.

The regulator arrangement just described would be quite flexible in application since the counter-electromotive-force machine could be designed to control a generator of any size without increasing the tube rating required. In some cases, however, the complication of an extra machine might be undesirable, and therefore the modification shown in figure 6 was developed. The excitation of the alternator is supplied by a standard shunt machine. The shunt field is also connected in the plate circuit of the rectifiers so that the rectifier plate current opposes the exciter field current produced by the exciter terminal voltage. Hence an increase in alternator terminal voltage will produce an increase in rectifier plate current just as before, and this will decrease the total field excitation of the exciter with a corresponding decrease in the exciter terminal voltage thus bringing the alternator voltage back to normal. There will also be the second order effect of the decreased exciter terminal voltage on the exciter field excitation produced by the ordinary action of a shunt machine, and this will be in the proper direction for assisting regulator action. The circuit of figure 6 was even more effective than that of figure 4 utilizing the same machines as before. When properly adjusted, there was no readable change in voltage from full load to no load. The oscillograms shown in figures 7*a* and 7*b* illustrate the speed of operation of the regulator which is again largely a function of the machine time constants.

This method could be applied to large machines by increasing the rating of the tubes used, or by providing an exciter with 2 field windings. One of these windings would be used as the regular shunt field, and the other would be separately excited by the rectifier tubes. By properly proportioning the separately excited winding, small tubes could be used to control the larger machines. The addition of a low-rating single-phase voltage-adjusting transformer between the source and the nonlinear control circuit would permit operation at any desired voltage above or below nominal rating.

## Conclusion

Because of the wide variation possible in machine constants no definite comparisons between this and other types of regulators can be made. Even under the conditions which this circuit was tested, however, it produced sensitivity and operating speed comparable with any of the existing electronic types with the decided advantage of simplicity of design. It has no moving parts, and the only attendance required would be the periodic inspection and testing of the rectifier tubes. Even if both tubes should fail simultaneously in service, a very unusual occurrence, the worst possible result would be the operation of the alternator at light load with a field excitation corresponding to normal voltage at full load. In case of short circuits on the system, the field excitation can only exceed that required to maintain normal voltage at full load by a predetermined amount, and hence the severity of short circuits will be lessened. If the frequency drops, the regulator will still exercise considerable regulatory action at subnormal voltage. If the frequency rises the control circuit will be sensitive at a higher value of voltage, and would regulate for this voltage if the field excitation for maintaining this voltage were available. Usually, however, the field excitation would be only slightly greater than normal full-load value, and the regulator would be inoperative except at light loads.

Thus we see that the regulator herein described has a number of advantages over other types without any apparent disadvantages.

## Special Uses for the Automatic Oscillograph

(*Continued from page 440*)

110-kv system. Applying the 6 volts direct current to this element gives an offset to the a-c wave during the interval that the tripping circuit is open. This is shown in figure 4. A similar arrangement of connections is made to the carrier receiver relay on the second 132-kv circuit and the d-c offset is obtained on another a-c voltage element of the oscillograph. The oscillograph battery is used for the offset on one circuit, and in order to eliminate the possibility of short-circuiting the secondaries of 2 potential transformers, a separate battery is used for the offset on the other circuit.

With this arrangement it is possible to check the over-all time required for the relays on each circuit to operate and open the trip circuit, and also the time required for them to reset and stop carrier after the fault is cleared. Comparing the times required by the relays on each circuit with the times obtained on the previous calibration and test, will indicate any change in total time which has taken place. A change in the total time may be due to any one of a number of relays, but by checking this total time it is possible to determine when a special calibration and test should be made on the individual relays.

## Conclusions

The operating records shown indicate that the use of the automatic oscillograph in locating faults, affords a means of reducing the cost of patrolling circuits after trip-outs. The annual saving, especially on systems composed of long circuits and whose terrain is subjected to a large number of electrical storms, makes the installation of several automatic oscillographs a profitable investment.

Temporarily connecting the automatic oscillograph to obtain a complete over-all check of the carrier-current-controlled relays is a new aid in insuring the correct operation of the relay protection for all types of trouble.

By using the oscillograph to indicate the performance of the carrier-current-controlled relays for faults both inside and beyond the protected section, complete over-all checks can be made less frequently with a subsequent saving in maintenance costs.

# Discussions

## Of AIEE Papers—as Recommended for Publication by Technical Committees

ON THIS and the following 4 pages appears a part of the discussion presented at the electrophysics session of the AIEE winter convention, New York, N. Y., January 28, 1937. Other discussion of winter convention papers will be published in later issues. Authors' closures, where they have been submitted, will be found at the end of their respective papers.

Members anywhere are encouraged to submit written discussion of any paper published in Electrical Engineering, which discussion will be reviewed by the proper technical committee and considered for possible publication in a subsequent issue. Discussions of papers presented at an AIEE meeting or convention are closed 2 weeks after presentation. Discussions should be double-space typewritten and submitted in triplicate to C. S. Rich, secretary, technical program committee, AIEE headquarters, 33 West 39th Street, New York, N. Y.

## A-C Characteristics of Dielectrics—II

**Discussion and author's closure of a paper by Alfredo Banos, Jr., published in the December 1936 issue, pages 1329–37, and presented for oral discussion at the electrophysics session of the winter convention, New York, N. Y., January 28, 1937.**

J. B. Whitehead (The Johns Hopkins University, Baltimore, Md.): Only a few years ago our knowledge of the nature of dielectric loss was extremely vague. With increasing importance of dielectric loss and phase difference in high-voltage insulation, however, it was soon realized that the d-c phenomenon of residual charge or dielectric absorption must be related to dielectric loss. Theories as to the cause of dielectric absorption were not then, nor are they now, in quantitative accord with experiment. Consequently Von Schweidler, leaving aside the question of theory, substituted the relaxation function $\varphi(t)$, expressed as current in the normal a-c power expressions, and derived the values of both in-phase or power, and quadrature or capacitance components of the periodic current of a capacitor. These values both involve $\varphi(t)$ which consequently had to be determined for their evaluation. Now $\varphi(t)$ can be determined from d-c experiments. It so happens, however, that $\varphi(t)$ so determined, is rarely such a form that it can be expressed in a single term. All such decaying functions, however, can be expressed as a sum of negative exponential terms, and these are readily handled in the Von Schweidler formulas. If, however, the number of such terms necessary to represent $\varphi(t)$ is large, the computation becomes rather burdensome.

The method of 3 exponentials has been developed because it has been found that in the range of power frequencies, 3 terms are amply sufficient: first, for accurate computation of the a-c loss from the d-c characteristics of the material, second, the division of that loss into its 2 components due to dielectric absorption and anomalous conduction, respectively, and, third, because this analysis provides information upon which studies looking to the improvement of any particular insulation may be based.

The present paper shows that for agreement between computed and measured values of the capacitance component of current, the curve of $\alpha(t)$ must be extended further in the direction of $t = 0$, than is the case for the power component. Bañios has given a very clear analytical explanation of why this is so.

**M. G. Malti** (Cornell University, Ithaca, N. Y.): I have been interested in theories of dielectrics for some time. To me a physical theory consists of linking physical facts with mathematical relations in a one-to-one correspondence so that every mathematical relation corresponds to a certain physical fact and vice versa.

The "method of 3 exponentials" described in this and the previous paper does not state explicitly what the 3 exponentials represent physically. Unless there is a physical basis for the 3 exponentials, I feel inclined to state that the method is purely a curve-fitting process and has nothing to do with the "A-C Characteristics of Dielectrics." Indeed while these exponentials were used by the authors to "fit" the relaxation curve, I see no reason why that same curve could not be just as well (perhaps much better) "fitted" by a polynominal or any other of the myriads of mathematical functions known to mathematicians and engineers.

The point I should like to make is this: Many of the so-called theories of dielectrics have been nothing but curve fitting processes. Unfortunately physicists are too busy splitting atoms and otherwise probing into the constitution of matter to help us with our immediate practical problems of dielectrics and magnetics. Those of us who are concentrating our efforts on such studies would do well to emulate the physicists and devote more attention to the fundamental *physical* phenomena underlying observed facts.

**W. A. Del Mar** (Habirshaw Cable and Wire Corporation, Yonkers, N. Y.): It may seem like quibbling to take exception to the use, by Bañios, of the expression "predetermination of a-c characteristics" but I think that a very incorrect impression of the paper is given thereby. The author's accomplishment is not one of prediction but of correlation between the residual relaxation curve obtained by d-c measurements and the power factor obtained by tests at 60 cycles. This is done by the resolution of the residual relaxation curve into the sum of a series of exponential curves. The same thing would be done by using some other empirical formula for this curve. When one writes a theoretical paper on the predetermination of performance of a dynamo, one implies the ability to predict the performance of the dynamo from the design, before the dynamo is built. In the Bañios paper the dielectric must be in existence and can be tested with alternating current as easily as with direct current.

A means of really predicting power factor of impregnated paper from d-c measurements of oil and paper before impregnation was given by Del Mar and Hanson in June 1922 and the curve given by Hanson for petrolatum impregnated cables (AIEE TRANSACTIONS, volume 41, 1922, page 624) is very striking in its close co-ordination between the prediction and the measured value. This method of predicting power factor is based on the conventional one-minute resistivity of the cable oil. If the residual relaxation function were always the same, a single point, such as corresponding to one minute, would suffice to establish a connection between the one-minute $\frac{dE}{dI}$ or conventional resistivity, such as shown by Hanson's curve. If, however, the residual relaxation function is variable and must be represented by the sum of, say, 3 exponential fuctions, the factors representing the magnitude of these components are likely to vary with different oils and papers and true prediction of power factor (that is, prediction from the properties of the oil and paper, before they are united), will be impossible unless these factors are known for the oils and papers concerned. It would be a worth-while research to develop a simple means of predetermining these factors.

I have a classification for researches which is as follows:

1. Those which are headed somewhere and get there.
2. Those which are headed somewhere and get somewhere else.
3. Those which are headed somewhere and get nowhere.
4. Those which are headed nowhere and get somewhere.
5. Those which are headed nowhere and get nowhere.

When I first read Bañios' paper and my eye was caught by the word "predetermination," I thought that his research belonged in class 2, but I now see that it really belongs in class 1.

**E. W. Greenfield** (Anaconda Wire and Cable Company, Hastings-on-Hudson, N. Y.): As Bañios has pointed out, the frequency function of the quadrature component of absorption permits contributions from the unobserved so called residual relaxation function which must be taken into account in order to accurately predict the a-c dielectric constant from the d-c absorption curves. The initial residual relaxation function is the difference between the relaxation function of the exponential of shortest time constant, and the relaxation function of that part of the initial curve not recorded by the oscillograph and expressed also in exponential series. When this residual relaxation function is large, its contribution is large and the "3 exponential" computed absorption component of capacity will be appreciably smaller than observed by frequency measurements. Another way of expressing the above is to say that the effective time constant of the d-c characteristic as computed from the experimentally taken oscillograms is too large when no account is taken of the initial unrecorded characteristic which has generally smaller time constants. The smaller the time constants, or the steeper the slope, of this unrecorded portion, the greater the deviation between computed and observed values.

If the frequency-capacity variation for the dielectric be available, a check of the range of frequency over which the absorption component of dielectric constant falls before reaching constant value will immediately indicate the range of time necessary for the oscillograph to accurately record the d-c characteristic. Where the dielectric has an extended frequency range of capacity decrease, the time constants or, for simplification, the effective time constant of the exponential function series representing the whole initial d-c characteristic, will be small and considerable contribution can be expected from the higher frequency terms. Where the frequency range of capacity is small, not over 500 cycles per second, oscillograph records starting at one millisecond may yield quite accurate prediction of the absorption component of capacity at 60 cycles.

In the experimental work on dry paper referred to by Bañios, AIEE TRANSACTIONS, volume 53, 1934, page 1389, Whitehead and I have shown in figure 4, curves of capacity plotted against frequency for a cable paper specimen of varying degrees of dryness. Inspection of these curves indicates that the range of frequency over which the capacity is seen to decrease is different for each moisture condition, being smaller in the drier state. For example, when dried at 765 millimeters of mercury, the capacity decreased continuously from its 60-cycle value to become constant at 3,000 cycles per second. On the other hand, for the paper in its driest state, the range of capacity decrease was only over 500 cycles. From this it is evident that the form of the relaxation function of the dielectric has been altered by its change in residual moisture content. This is also evident on figure 5, where the short-time d-c discharge curves of the dielectric are shown. Increase of moisture content is apparently responsible for addition to the relaxation function of components of small time constant, and thus causes an increase of the so-called residual relaxation function. Based on the frequency-capacity curves of figure 4, it may then be predicted that the correlation of absorption component of capacitance between a-c and d-c measurements should be better for the driest condition and poorest for the most moist condition. That this is so is evident from table I, which gives the power factor and capacity analysis of the d-c oscillograph curves. In columns 8 and 9 the agreement between observed and computed values of absorption capacity is generally better as we proceed from moist conditions to dry conditions of the dielectric.

**Alfredo Bañios, Jr.:** I feel grateful to Whitehead for his pertinent remarks which ably summarize both the purpose of our earlier researches and the goal actually attained in these studies. It is clear from our publications that, in this aspect of the work, we have at no time professed to give a theory of dielectrics, but that we have simply brought Von Schweidler's method of a-c computation to the domain of experimental quantitative verification and that, in so doing, we have developed a method of separating dielectric loss into its 2 fundamental components: reversible absorption

and anomalous conduction. The importance of this achievement, not only from the theoretical point of view, but also from the standpoint of high voltage insulation design, is now generally well recognized and need not be further stressed.

In connection with Malti's discussion I must again reiterate that we offer no theory of dielectrics; hence our "3 exponentials," which are only a means to an end, have no physical significance. In fact, casual study of our method of "curve fitting," as explained in our first publication, should leave no doubt that, on account of its inherent indeterminateness, the 3 exponentials lose all hope of ever attaining a definite physical meaning. I do insist, however, that from among the myriads of junctions known to mathematicians and engineers, the exponential function is the best suited for our purpose. Indeed, a clear understanding of Von Schweidler's method of a-c computation depending, as it does, on the determination of 2 infinite definite integrals whose convergence requirements must be carefully inspected, should make it plain why the exponential function is admirably suited for the purpose at hand and why any other function, a polynomial, for example, while fitting the relaxation function accurately for a limited range of time, could not yield at all reasonable values for the $A$ and $B$ integrals in Von Schweidler's method.

Referring to Del Mar's discussion I agree that the title "correlation of a-c and d-c characteristics of dielectrics" would undoubtedly give a better idea of the subject matter treated. I do take exception, however, to the statement that correlation between the d-c characteristics and the a-c power factor could be attained by the use of any empirical equation representing the relaxation function, for, as explained in the preceding paragraph, the exponential is the simplest function which complies with the convergence requirements of the method.

To E. W. Greenfield I wish to express my appreciation for his excellent and thorough discussion of my paper, bringing out clearly the correct interpretation of our results together with an enlightening set of remarks based on his own experimental results which, in themselves, constitute a valuable supplement to our conclusions.

## Dielectric Strength of Transformer Insulation

**Discussion and authors' closure of a paper by P. L. Bellaschi and W. L. Teague published in the January 1937 issue, pages 164–71 and 137, and presented for oral discussion at the electrophysics session of the winter convention, New York, N. Y., January 28, 1937.**

**J. B. Whitehead** (The Johns Hopkins University, Baltimore, Md.): The fundamental dielectric properties of an insulating material can rarely be conserved and maintained through the processes of manufacture, transportation, installation, and operation of assembled equipment. It is for this reason that the results and values obtained in laboratory research may not be immediately applied in manufacture. The paper of the present authors and that of Montsinger, a few months ago, describe results of breakdown tests on oil and laminated materials with almost identical types of test sample. These test samples, however, in all cases employ an electrode with square edges and without guards which is recognized by long experience as being a very unsuitable set-up for a study of the inherent characteristics either of a liquid or a solid. Obviously, therefore, these and similar tests cannot be considered as tests of the properties of the insulating materials, but are tests of these materials in relation to special types of electrodes. Moreover, these electrodes are known to give highly irregular fields, brush discharge, corona, etc., long recognized as disturbing influences in breakdown tests.

These things may be said without in any way questioning the practical importance of such tests. They are evidently designed to cover the actual conditions under which the insulation must be assembled in manufacture. This is obviously a sufficient justification for any design of test sample. I judge that the use of a sharp edge is intentional so as to produce the worst conditions, but if the tests are in accord with measurements on assembled power transformers, as is indicated, the question arises as to whether the breakdown strength of these might not be improved by looking for all sharp edges and rounding them off.

It seems to me idle in view of the conditions of the tests, involving as they do the continued presence of brush discharge and corona, to write formulae for the voltage-time curves, or to speculate as to an explanation of their unusual shape. In view of the results of many careful experiments on the inherent properties of the materials themselves, I strongly suspect that the sharp rise of the curve of measured breakdown voltages for short impulses does not give the actual voltage on the sample, but that within this region the rise of voltage above the horizontal portion of the curve is due to a loss in voltage within the brush discharges, corona, and local capacitances within the sample itself. Support of this view is found in a number of cases in which the solid insulation broke down at points outside the electrode.

**J. R. Meador** (General Electric Company, Pittsfield, Mass.): The authors, under the heading of "Combined Solid and Liquid Insulation," give impulse and 60-cycle breakdown voltages for an insulation barrier consisting of 2 0.056-inch thick fullerboard sheets and 3 1/8-inch oil ducts arranged alternately. The impulse tests were made with waves having durations of from 0.35 microsecond to a full 40 microseconds. Over this range the impulse ratio on repeated applications of voltage is shown to be practically constant at 2.2. In a previous paper ("Insulation Coördination of Transformers—II," by Bellaschi and Vogel, June 1934 issue of ELECTRICAL ENGINEERING) similar tests are made on 2 larger barriers. These tests showed an impulse ratio on repeated applications of voltage of 1.79 and 1.78. Three possible explanations for this difference of impulse ratio are as follows:

1. A change of technique giving different results.
2. A change in the shape or size of the electrodes.
3. A change in the insulation arrangement.

Assuming that the difference is not due to cause 1, it appears that different insulation arrangements and electrode sizes and shapes have an effect on the repeated shot impulse ratio. Consequently, it does not appear logical to use the maximum impulse ratio of 2.2 for determining the impulse test for transformers of all voltage classes.

The tests on the assembled transformers presumably were made without damage to the transformers. If no damage occurred, then the "turn up" of the voltage at short "times" on figure 10 has significance only if the relation between the applied voltage and the breakdown voltage is constant in each region.

With regard to the switching surge tests shown on figure 10, what was the frequency of the switching surges as compared with the lowest natural frequency of the transformer winding?

It has been shown ("Effect of Transient Voltages on Power Transformer Design," K. K. Paluev, AIEE TRANSACTIONS, volume 48, July 1929, page 681) that oscillatory waves caused by switching or arcing grounds may have frequencies comparable with the natural frequencies of transformer windings. This is of importance since an oscillatory wave applied to an unshielded transformer will cause high concentrations of voltage in the winding if the frequency of the wave is within plus or minus 40 per cent of one of the natural frequencies of the winding. If the frequencies of the switching surges represented by the points on figure 10 were considerably less than the lowest natural frequency of the transformer winding, the effect of these tests on the winding was not comparable with the stresses that may occur in service.

**V. M. Montsinger** (General Electric Company, Pittsfield, Mass.): This paper gives very complete data on the volt-time curves on various oil gaps and on single sheets of pressboard. The statement made by the authors that more data were required to establish adequately the volt-time characteristics of insulation needs to be qualified. If they are referring only to the characteristics of oil alone and to solid insulation alone, I more or less agree with them, but if they refer to insulation as used in transformers, particularly major insulation, I must take exception to the statement in so far as it relates to the increase in the breakdown strength for short waves of the order of approximately one microsecond and less.

My experience shows that the volt-time curve of solid insulation and oil in series starts bending up in the neighborhood of 2 to 3 microseconds and bends up considerably more than shown in either figure 6 or figure 7 of the paper. In fact, considering that the volt-time curve of oil alone as shown in figures 3, 4, and 5 starts bending up around 10 microsecond—and the breakdown strength increases in the order of 100 per cent for 1/2 microsecond time—it is to be expected that the volt-time curve of transformer major insulation, where oil is used in series with solid, should not only

start bending up earlier but also should bend up more than shown by the authors' curves for pressboard alone. Figure 4 shown in the closure of my paper "Breakdown Curve for Insulation," given (in the April issue of ELECTRICAL ENGINEERING) at last winter's convention, shows the bend-up in the curve as indicated by tests made by both Vogel and myself on various thicknesses of barriers. This curve shows that the breakdown strength at one microsecond is 25 per cent greater than the full wave breakdown strength and at $1/2$ microsecond is approximately 50 per cent greater than the full wave strength.

Since the presentation of my paper last winter, our Laboratory has made many hundreds of tests to determine the shape of the volt-time curve from approximately 3 microseconds back to $1/2$ to $1/4$ microsecond on barriers of different thicknesses and based not only on single shot breakdown, but on repeated applications of voltage. A still better gauge than repeated voltage breakdown is the point at which corona starts to damage the insulation. This also has been investigated. While the tests are not yet completed, results up to the present time indicate that for full waves the injurious corona point will range anywhere from approximately 70 to 90 per cent of the single shot breakdown depending on the kinds of electrodes used. For bare electrodes with sharp edges injurious corona may start around 65 to 70 per cent while for well insulated electrodes injurious corona may not start until about 90 per cent of the breakdown strength is reached. For average conditions I think we can assume that injurious corona (or breakdown if subjected to sufficient number of shots) occurs at 80 per cent of the single shot breakdown value. This applies to either solid or solid and oil in series.

The shape of the curve is somewhat similar to but does not bend up quite as much as the single shot breakdown curve as shown in figure 1. The purpose of these tests is, of course, to obtain basic data for protecting transformers in service against both long waves and short waves. As it is planned to give the results of these tests in a paper for a later convention, no attempt will be made to present the data in this discussion. It can be seen therefore, that before rules can be drawn up for testing transformers on the front of waves, we must have considerably more data than has been published up to the present.

Last winter when my paper on "Breakdown Curve for Insulation" was presented, the question was raised as to whether major insulation of transformers, consisting of solid insulation and oil in series, had the flat characteristics; that is, the constant breakdown strength over the region in time from approximately 3 microseconds to 1, 2, or 3 cycles of 60-cycle voltage. Since that time tests have been made on a barrier consisting of 2 $1/32$-inch pressboard sheets separated by $1/16$-inch oil duct. The results of these tests are shown in figure 2. It will be noted that where 50 per cent of the space is occupied by oil, the other 50 per cent by solid, the shape of the curve is essentially the same as the curve for a single sheet of pressboard.

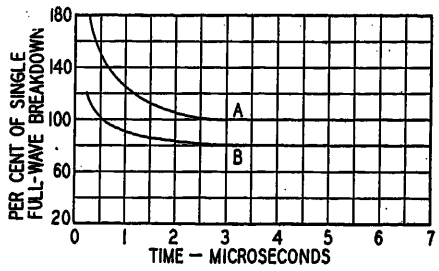

**Fig. 1. Volt-time curves of insulation consisting of solid and oil in series, simulating major insulation in a transformer**

*A*—Breakdown by single application of voltage
*B*—Breakdown by repeated application of voltage (approximate) 1.5 x 40 impulse wave (positive or negative)

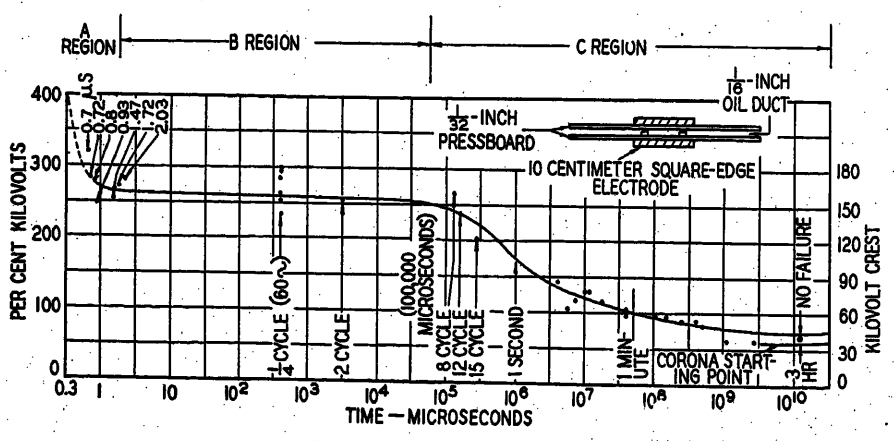

**Fig. 2. Volt-time curve of single shot breakdown of 2 $1/32$-inch pressboard and $1/16$-inch oil duct in series in oil at 25 degrees centigrade**

In view of the results which our laboratory has obtained on the breakdown strength of many barriers on front of wave tests, as compared with breakdown for full waves, I am at a loss to understand why the authors' tests show the same breakdown strength of 300 kv for 0.35 microsecond as for $2\frac{1}{2}$ microseconds on the insulation barrier consisting of 2 0.056-inch thick pressboard sheets and 3 $1/8$-inch oil ducts arranged alternately, as given on page 170.

I believe it can readily be appreciated that the main difference between my views and the authors' views is that the authors feel that when short or front of wave tests are made on transformers, the kilovolt values should not be allowed to exceed the kilovolt values used for the full wave tests, whereas my views, as based on laboratory tests, indicate that a somewhat greater increase in kilovolt values can be used when testing transformers on the front of the wave.

As to the claim that the impulse test kilovolt should be 2.2 times the 60-cycle crest test, many tests made on actual transformer windings have shown impulse ratios varying from about 2.2 to 3, the general average being approximately 2.6. This applies only to single wave impulse strengths of major insulation.

Under repeated voltage conditions the impulse strength of the major insulation is obviously lower than 2.2 to 3 times the 60-cycle one-minute strength, the reduction depending upon the difference between the impulse single voltage application and impulse repeated voltage application strengths of the insulations involved. The repeated impulse strength of transformer windings is in the order of 80 per cent of the single shot strength. That is, it will range from about 1.75 to 2.4 with a general safe average value of approximately 2.0 times the 60-cycle one-minute strength. Therefore for a 138-kv transformer the impulse kilovolt should not exceed $2\sqrt{2} \times 277 = 782$ kv which is quite close to the present AIEE recommended value of 745 kv which is 105 per cent of the bushing flashover.

I. W. Gross (American Gas and Electric Company, New York, N. Y.): This paper is a worthy contribution to the rather meager published data on the electrical strength of insulation typical of that used in transformers. I particularly wish to compliment the authors on the completeness with which they have substantiated their test curves by showing test points in all of their curve data.

In regard to the switching surge tests, it is not clear from the paper if one impulse only was applied or whether the surge consisted of several high frequency cycles similar to actual switching surges recorded in the field by the cathode ray oscillograph. If only one impulse was used it seems possible that the values of insulation breakdown might be somewhat lower than given by the authors.

The tests shown graphically in figure 10 throughout a wide range of voltage conditions on full size commercial transformers are particularly interesting, but the logic behind some of the conclusions drawn from that data is difficult to follow.

First, it is stated the test in region *E* (these being front of wave tests where the wave rose to crest in from $1/2$ to 1 microsecond) encroach on the margin of the

insulation impulse strength. Yet it will be noted one transformer withstood 15 tests in this region, and the other 4 tests. It is hard to understand why they believe the test in this case was excessive, and there appears to be nothing in the paper to bear out this statement.

They further state that "these tests on the transformer are amply indicative that the voltage time characteristics of this and other apparatus of the kind is similar in shape to that for oil and fullerboard." While I do not question the latter part of this conclusion, the fact must not be lost sight of that the transformers *withstood* the tests, but the samples of oil and fullerboard *failed* all under similar voltage test conditions. It seems quite possible, therefore, that the transformers may have a safe impulse strength, at some points on the volt-time curve given considerably greater than the values at which they were tested.

The authors further state that the large number of tests made on the 2 transformers with impulse and 60-cycle voltages "are sufficient to establish the adequacy of a transformer design for practically all conditions of service." This statement assumes a great deal as to service which often may not be reasonably attainable in practice.

I certainly hope their statement is correct; for if so, most of us would cease to worry about many of the refinements in supplying transformers with protection which have recently been advocated.

It is true the large number of tests on these 2 transformers do tend to give us some assurance that transformers can be built to adequately meet a given set of insulation specifications; but I believe we still have with us the practical problem of protecting these transformers under the varying conditions of service encountered in the field.

**P. L. Bellaschi and W. L. Teague:** In his discussion, V. M. Montsinger calls attention to the relation between the impulse strength of insulation for a single voltage application and for repeated applications. His conclusion is that the impulse voltage on transformers should not be more than 2.0 times the 60-cycle one-minute strength, thus for a 138-kv transformer the impulse kilovolts should not exceed $2.0\sqrt{2} \times 277 = 782$ kv. This is an important conclusion to consider as it essentially comprehends the various points considered throughout the discussion. In this connection reference to figure 10 of the author's paper clearly shows that impulse tests up to $2.2\sqrt{2} \times 277 = 860$ kv could be applied repeatedly on the 132-kv transformers, both shell and core types. Similarly, in a previous paper where the fundamental relations on possible insulation deterioration on repeated impulses of long, medium, and very short duration were first set forth ("Factors Influencing the Insulation Coördination of Transformers—II," P. L. Bellaschi and F. J. Vogel, ELECTRICAL ENGINEERING, June 1934), attention was called to repeated tests on 230-kv transformer design at $461\sqrt{2} \times 2.2 = 1430$ kv.

In Montsinger's discussion, he refers to tests made by both Vogel and himself on various thicknesses of barriers, and that they showed an increase in breakdown strength at very short times. I would like to call attention to the fact that Vogel has not published data showing this to be the case for repeated tests, as his data are shown in the paper just referred to. It should also be noted that the data previously reported referred to a particular type of barrier and electrode arrangement, representative of the higher voltage transformers, and not including other arrangements used on lower voltage transformers.

Curve *A* of figure 1 for the breakdown of insulation by single application of voltage is well known. It appears, for example, in figure 1 of the paper cited in a previous paragraph. The curve *B* of figure 1 for repeated applications is interesting, but it is not clear from the discussion whether the author considers this as a specific or a general curve. For example, tests have been made where the corresponding curve *B* rises much higher on very short impulses than indicated in figure 1 ("Direct-Stroke Protection of Distribution Transformers," H. V. Putman, *Electric Journal*, February 1937, page 60). The converse is possible for other apparatus. Curves such as *B* of figure 1 need be clearly specified with reference to the apparatus or test specimen, number of voltage applications, and similar essential information.

Montsinger has presented additional data of interest on the characteristic of insulation over the "region *B*," that is, from some 2 to approximately 100,000 microseconds. His figure 2 further confirms that the voltage characteristic of transformer insulation is practically flat over the entire range of medium and long impulses and switching surges.

The point raised by Meador that change in shape or size of electrodes or in the insulation arrangement may result in different levels of possible damage is quite true as has been discussed in the previous paragraphs. Thus distribution apparatus has a relatively higher strength and endurance to repeated impulses than the higher-voltage class insulation. Again, the ratio of 2.2 indicated in figure 10 has been established by repeated tests.

The question of switching surges in relation to so-called possible resonance effects has always been intriguing. Available data (see, for example, *C.I.G.R.E.*, 1935, paper 353, and similar data published here) indicate that true oscillatory voltages superimposed on the 60-cycle wave are relatively of low value. The higher values that may be encountered are impulsive in character. For these reasons the tests applied to one of the transformers are amply severe both from the standpoint of oscillations and amplitude. Repeated tests running into the hundreds were applied at values $3\frac{1}{2}$ the operating voltage and in addition, as indicated in figure 10 the voltage was raised to 5 times and more the operating voltage. The character of these switching voltages is abruptly steep and enduring for hundreds of microseconds, fully developing all internal oscillations. These would produce stresses more severe than could be accounted for even had the wave been in resonance and of such amplitude as has been encountered in practice. Our own experience has not yet shown failure due to switching causes even on under-insulated transformers.

We well agree with Whitehead that the tests and data in the paper are primarily of an engineering character and are directed chiefly toward engineering progress in insulation co-ordination. Though the results also bear out interesting findings of a theoretical nature. It is amply apparent from this discussion that in the design of apparatus all possible causes of corona should be completely or practically suppressed. The rise in the voltage time-lag characteristics, to which Whitehead refers, has also been found by other investigators both in this country and abroad (on oil, for example, see *C.I.G.R.E.*, 1935).

I. W. Gross rightly raises the point whether the limited tests applied to the 2 transformers in the region *E* (figure 10) do encroach on the insulation, since they withstood the tests. A considerably greater number of repeated tests indicate that damage would result. It is apparent from this cumulative effect that a smaller number of tests would also encroach, in a certain measure on the margin factor of the insulation.

The voltage values in region *D*, *C*, and *B* were limited by the rod gap. Were no gap employed the bushing would naturally set a limit of the same relative order. These hold values should be considered in relation to the major insulation strength and the strength throughout the entire winding for the corresponding stresses set up. To continue these tests to breakdown would require an increase in rod gap spacing or what amounts to the same thing, a higher voltage bushing. Between the ultimate strength and the hold strength naturally a margin exists.

Even after fulfilling by proper design and adequate test the requirements in a transformer, the problem of protection remains. It was not the intention a all to convey such idea that this problem would be dispensed with. One purpose of this paper, supported by the tests, is to call attention to the full significance of the 60-cycle and impulse tests as an index to an expectancy of good service in the transformer. The preceding paper to this one ("Factors Influencing the Insulation Coördination of Transformers—II," P. L. Bellaschi and F. J. Vogel, ELECTRICAL ENGINEERING, June 1934) presents fundamental considerations underlying the problem of protection in relation to the characteristics of substation apparatus. We wish to recall the attention to these principles, even though each case of application may in addition present problems inherent in the particular service conditions.

The switching surge applied in the insulation tests appears in oscillogram *D* (figure 8). The surge is oscillatory; besides 60-cycle voltages of equally great amplitude were applied the insulation for several oscillations, indicating with adequate assurance that the voltage-time characteristic for the various possible conditions of switching can hardly be other than a flat curve. The transformer was subjected (figure 1) to a large number of repeated surges at $3\frac{1}{2}$ times the operating voltage, then in addition at 5 times and more as indicated on figure 10. These switching voltages are abruptly steep and enduring for hundreds of microseconds, comprising a severe test.

# Elihu Thomson—

## March 29, 1853—March 13, 1937

CONCLUDING one of the longest, most varied, and most fruitful careers in electrical engineering, Elihu Thomson died at his home in Swampscott, Mass., on March 13, 1937, just a few days before his eighty-fourth birthday. Indisputably the dean of American electrical engineers, he was regarded as being second to none among the small group of his contemporaries upon whose inventive genius the electrical industry of the world was founded and through whose perseverance and keen foresight it grew.

Recognized for his character and ability, and honored by his contemporaries throughout his lifetime, few men, if any, have contributed more to the progress of the world than did Elihu Thomson, and fewer still have lived to see such full fruition of their ideas. He was one of the last of the original group of great electrical pioneers.

His signature was on the "call" for the May 1884 organization meeting of the AIEE, and Doctor Thomson became a charter member of the Institute. He maintained an active affiliation for the remainder of his life. He is survived by only 3 other charter members whose names still appear on the active list. Although not caring for administrative work, preferring to remain "in the ranks" and closer to his work, Elihu Thomson was elected a vice-president of the Institute in 1887 and immediately upon completion of his term in that office became in 1889 the fifth in the line of great leaders who have guided the Institute's destiny.

Doctor Thomson was particularly active in local Institute affairs, and a perusal of the AIEE PROCEEDINGS prior to 1910 will show that he presented papers and discussions at many Section meetings. He served as a member of the Institute's committees on co-operative research and standardization from 1898 to 1900, and as chairman of the Edison Medal committee from 1911 to 1915. Thomson was not a prolific scientific writer, but the character of his writings is attested by the following papers published in the AIEE TRANSACTIONS:

1. NOVEL PHENOMENA OF ALTERNATING CURRENTS, volume 4, May 1887, page 160.

2. MAGNETISM IN ITS RELATION TO INDUCED ELECTROMOTIVE FORCE AND CURRENT, volume 6, May 1889, page 269.

3. PHENOMENA OF ALTERNATING-CURRENT INDUCTION, volume 7, April 1890, page 132.

4. COMPOUNDING DYNAMOS FOR ARMATURE REACTION, volume 12, June 1896, page 288.

5. A NEW FORM OF INDUCTION COIL, volume 14, July 1897, page 225.

6. CONDITIONS AFFECTING STABILITY IN ELECTRIC LIGHTING CIRCUITS, volume 28, January 1909, page 1.

In 1904 the Institute, in response to an invitation by an organization of associates and friends of Charter Member Thomas A. Edison, undertook the responsibility of making the awards of a gold medal now known as the Edison Medal. Elihu Thomson, in 1909, was the first to receive the award "for meritorious achievement in electrical science engineering, and arts, as exemplified in his contributions thereto. . . ."

In June 1928 the Institute was priviliged to give further recognition to Thomson's services and achievements. The constitution provides that Honorary Members may be chosen, upon the *unanimous* vote of the board of directors, "from among those who have rendered acknowledged eminent service to electrical engineering or its allied sciences." Prior to June 1928 the few distinguished persons thus elected all were from foreign countries, but at that time Thomson's name was included in a list of 5 outstanding American engineers unanimously endorsed by the directors.

### THOMSON'S EARLY LIFE

Elihu Thomson was born March 29, 1853, at Manchester, England, to an English mother and a Scotch father. The family came to the United States in 1858, settling in Philadelphia, Pa., where Doctor Thomson attended the public schools. Completing his preparatory education at the age of 11, he had to wait 2 years to meet the minimum age of 13 years required of high school entrants. During this 2-year period, with the encouragement of his parents, he devoted himself to his experiments and his hobbies. He constructed a friction type of electric generator from a wine bottle, and built Leyden jars to be charged by his generator; these and the other similar electrical apparatus of the time were followed by such things as batteries, and electromagnets and telegraph instruments in which the bare wire used for the windings was insulated by the laborious task of winding thread around it by hand. While still a child his interest in astronomy led him to construct his own telescope with the help of a friendly lens maker. In later life he continued the pursuit of this hobby, building powerful telescopes himself and grinding his own lenses.

After he graduated from Central High School early in 1870, he entered a laboratory as an analyst, but was appointed assistant professor of chemistry in the high school later in the same year. In 1876, at the age of 23, he was appointed professor of chemistry in the same school, but he had become deeply interested in the applications of electricity, and in 1880 resigned to devote his entire time to electrical research and development. He always had been fascinated by physical and chemical studies, and especially by electricity.

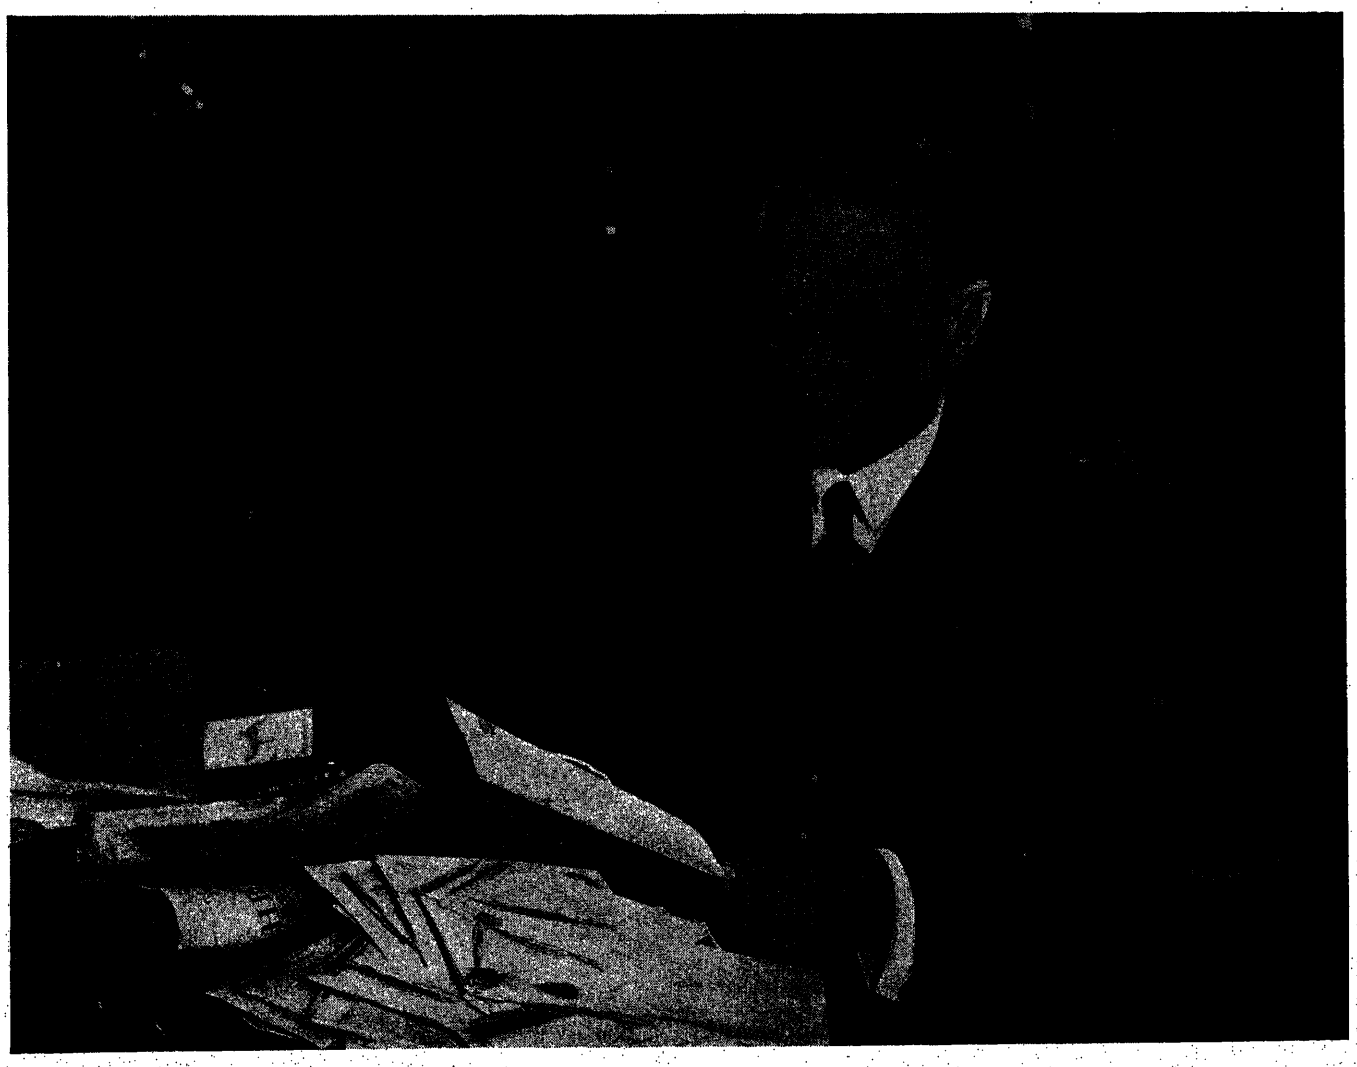
Possessed of a natural knack for construction and the use of tools, he gave what time he could spare from other duties to making such apparatus as he needed. In this way, before the age of 20, he had built induction coils, electromagnets, cameras, chemical balances, and many other devices. In his early twenties he constructed numerous pieces of scientific apparatus for demonstration and laboratory use, including a compound microscope; also numerous electrical machines and a pipe organ with electrical action for which he made the pipes, windchest, bellows, keyboard, and all other parts.

### INDUSTRIAL DEVELOPMENT

When Doctor Thomson resigned his professorship at Central High School in 1880, he took charge of the commercial development of an arc-lighting system for the American Electric Company, a small firm that had been started in Philadelphia in 1879. At the same time E. J. Houston, his colleague at the high school and later a president of the Institute, resigned his teaching position and joined him in the business. Later in the same year the company moved to New Britain, Conn. E. W. Rice, Jr., subsequently a president of the Institute and president of the General Electric Company, accompanied Thomson as an assistant. In 1883 the modest establishment at New Britain was moved to Lynn, Mass., a "Lynn Syndicate," as it was called by Thomson and his associates, having bought control of the American Electric Company. At Lynn the name of the company was changed to the Thomson-Houston Company, and during these pioneer years Doctor Thomson was "electrician" and chief engineer, and many of the fundamentally important inventions upon which the business was established and grew were his. He shunned administrative duties, and the commercial destiny of the company was largely in the hands of Charles A. Coffin.

In 1892, the Thomson-Houston Electric

Company and the Edison General Electric Company were merged to form the General Electric Company. Thomson remained as consulting engineer and director of the Thomson Research Laboratories at Lynn. By his own choice he devoted his time and efforts to research and development rather than to administrative work. Charles A. Coffin became the first president of the new and rapidly expanding company.



### Honors Conferred on Thomson

Elihu Thomson probably was the most honored scientist in America. He was acclaimed by several colleges and universities, receiving the honorary degrees of master of arts (1890) from Yale University, doctor of philosophy (1894) from Tufts College, doctor of science from Harvard University (1909) and the University of Manchester (England) (1924), and doctor of laws from the University of Pennsylvania (1924). He was awarded many prizes, medals, and decorations, and had the distinction of being the only man to receive all 3 of the most important scientific medals of Great Britain: the Hughes Medal of the Royal Society, the Kelvin Medal, and the Faraday Medal of the Institution of Electrical Engineers. The Royal Institution of Great Britain elected Thomson an honorary member, the highest scientific honor that Englishmen can confer upon a foreigner. The complete list of awards, decorations, and medals received by him is impressive:

1. John Scott Legacy Medal, for electric welding, 1888
2. Grand Prix, Paris Exposition, 1889
3. Appointed officer et chevalier of the Legion D'Honneur, 1889
4. Certificate of award of gold medal, Columbian Exposition, 1893; no medal was received
5. First prize, Trans-Mississippi and International Exposition, Omaha, Nebr., 1898
6. Grand Prix, Paris Exposition, 1900
7. Rumford Medal, for electric welding and lighting, 1901
8. John Scott Legacy Medal, for constant-current transformer, 1901
9. Grand Prize, Louisiana Purchase Exposition, St. Louis, Mo., 1904
10. First Edison Medal of the AIEE, 1909
11. Elliott Cresson Medal of the Franklin Institute, 1912
12. John Fritz Medal, 1916
13. Hughes Medal of the Royal Society, London, England, 1916
14. Kelvin Medal, 1924
15. Franklin Medal, of the Franklin Institute, 1924
16. Faraday Medal, Institution of Electrical Engineers, 1927
17. Medal of the Verein Deutscher Ingenieure, 1935

In 1925 Thomson was designated as "father of protective grounding" by a resolution adopted by the Western Association of Electrical Inspectors. He was one of 6 official United States delegates to the chamber of delegates of the electrical congress in Chicago in 1893; president of the International Electrical Congress in St. Louis in 1904; a member of the World Engineering Congress at Tokyo, Japan, in 1929; and a United States delegate to the International Electrical Congress at Paris, France, in 1932. Many technical and scientific organizations including the Institute, had conferred honorary membership upon Doctor Thomson. These were:

1. Franklin Institute
2. Institution of Civil Engineers (Great Britain)
3. Institution of Electrical Engineers (Great Britain)
4. Royal Institution (Great Britain)

**A photograph showing Doctor Thomson on his eightieth birthday, reading some of the many congratulatory letters that came to him from all parts of the world on that occasion**

# In Memoriam

## ELIHU THOMSON

DR. ELIHU THOMSON, a charter member, the fifth president, and an honorary member of the American Institute of Electrical Engineers, died at his home in Swampscott, Mass., on March 13, 1937, about two weeks before his eighty-fourth birthday.

Beginning his electrical experiments at the age of eleven, when he had completed his preparation for high school but found it necessary to wait two years to meet the minimum age requirement for entrance, he built and operated several types of equipment, and quickly demonstrated his ability in fundamental science and also his remarkable inventive genius. After graduating from the Central High School in Philadelphia and teaching chemistry and mechanics in that school during the next ten years, he resigned in 1880 to devote his entire time to electrical research.

The American Electric Company which he joined soon became the Thomson-Houston Company and the latter merged, in 1892, with the Edison General Electric Company to form the General Electric Company, with which Dr. Thomson was connected until his death.

His more than 700 inventions included many of outstanding importance which added materially to scientific knowledge and laid the foundation for many significant developments in the electrical industry. The combination of marked scientific ability, broad vision, sound judgment and pleasing personality gave him a position of outstanding leadership throughout his long career.

He received the first Edison Medal awarded by the Institute, and received many of the most notable medals in the world, having been the only man to receive all three of England's highest scientific honors, the Hughes, Kelvin, and Faraday medals. He received several high honorary degrees, including Ph.D. ScD., and LLD. He was elected an Honorary Member by the AIEE and several other societies, and received other high honors in the United States and abroad.

Entering the Institute as a charter member, he immediately became active in its affairs, and was a vice-president 1887–89, and president 1889–90. He also rendered valuable services to the Institute as member of various important committees and as its representative in joint activities. He was transferred to the grade of Member in 1891 and to the grade of Fellow in 1913. He was elected an Honorary Member in 1928.

RESOLVED: That the Executive Committee of the American Institute of Electrical Engineers, upon behalf of the Board of Directors and the membership, hereby expresses its keen regret at the death of Doctor Thomson, and its deepest appreciation of his many outstanding contributions to electrical engineering progress, and be it further

RESOLVED: That these resolutions be entered in the minutes and transmitted to his family.

—AIEE Executive Committee, March 25, 1937.

### Outstanding Accomplishments

Perhaps the first great contribution to electrical engineering made by Elihu Thomson was his invention, in about 1879, of the 3-coil dynamo with its automatic regulator and other novel features, which formed the basis of the first commercially successful lighting system. This was manufactured by the Thomson-Houston Company in the early 1880's and quickly found its place not only in the United States, but also in several European countries. The machine was entirely automatic in its operation, and was so adjusted that it could maintain constant regulation of a system of many electric arcs, regardless of the number of arcs that might be turned on or off. The need for such a regulator and its general nature were suggested to him by his earliest serious electrical studies, which concerned the relations between the voltage and current in an electric arc, and which led him to the discovery that as the current increases the voltage decreases. This relation accounted for the instability of the arc and indicated what characteristics the dynamo should have. This 3-coil dynamo was a d-c machine, for at that time direct current was more easily handled than was alternating current, and had certain advantages for arc-lighting purposes. The same machine, however, with different connections, constitutes the 3-phase generator that is so important in present electric power installations, and was so represented by Thomson in his original patent application.

While he was working on his arc-lighting system, Thomson heard that Edison was tinkering with an incandescent lamp. Accordingly he went to Menlo Park to discuss the matter with Edison, who gave him a model of the lamp. This model subsequently was dissected by Thomson and Houston, with the decision that it never would amount to anything.

### Lightning Protection—Magnetic Blowout

About 2 years later, in 1881, he invented another important electrical device: the magnetically operated lightning arrester. Although this arrester was created for the particular purpose of protecting his arc-light systems from lightning, it was the invention of a fundamental method of breaking electrical circuits that has found numerous applications, one of the most important of which was by Doctor Thomson himself in control contactors for electric cars and trains. The device consisted of an insulator so placed between the poles of a magnet, and the whole so arranged with respect to the contacts or electrodes, that any arc forming was forced by the magnetic field to elongate itself to the breaking point, thus quickly and effectively interrupting the circuit. This principle is of as much importance today as it was then, for it is the foundation of several modern systems of switching large currents.

### Power Transmission

In those very early days of electrical engineering, long before the importance of electric power transmission and distribution was realized generally, Thomson devised the now commonly used method of transmitting electrical energy, stepping it down from high voltage with the aid of a local transformer for local consumption. This was set up as a working model for demonstration at the Franklin Institute in Philadelphia in 1879. A patent was applied for in 1885, and after a strenuous period in the patent office a fundamental patent for multiple-arc distribution systems with transformers was granted in 1902. During this same time Thomson developed and patented the procedure of grounding the secondary of the transformer as an additional safety measure for high-voltage operation. A notable characteristic of Doctor Thomson is indicated by his advice to the General Electric Company that this patent should be dedi-

## Future AIEE Meetings

Buffalo, N. Y., May 5–7, 1937

**Summer Convention**
Milwaukee, Wis., June 21–25, 1937

**Pacific Coast Convention**
Spokane, Wash., Aug. 30–Sept. 3, 1937

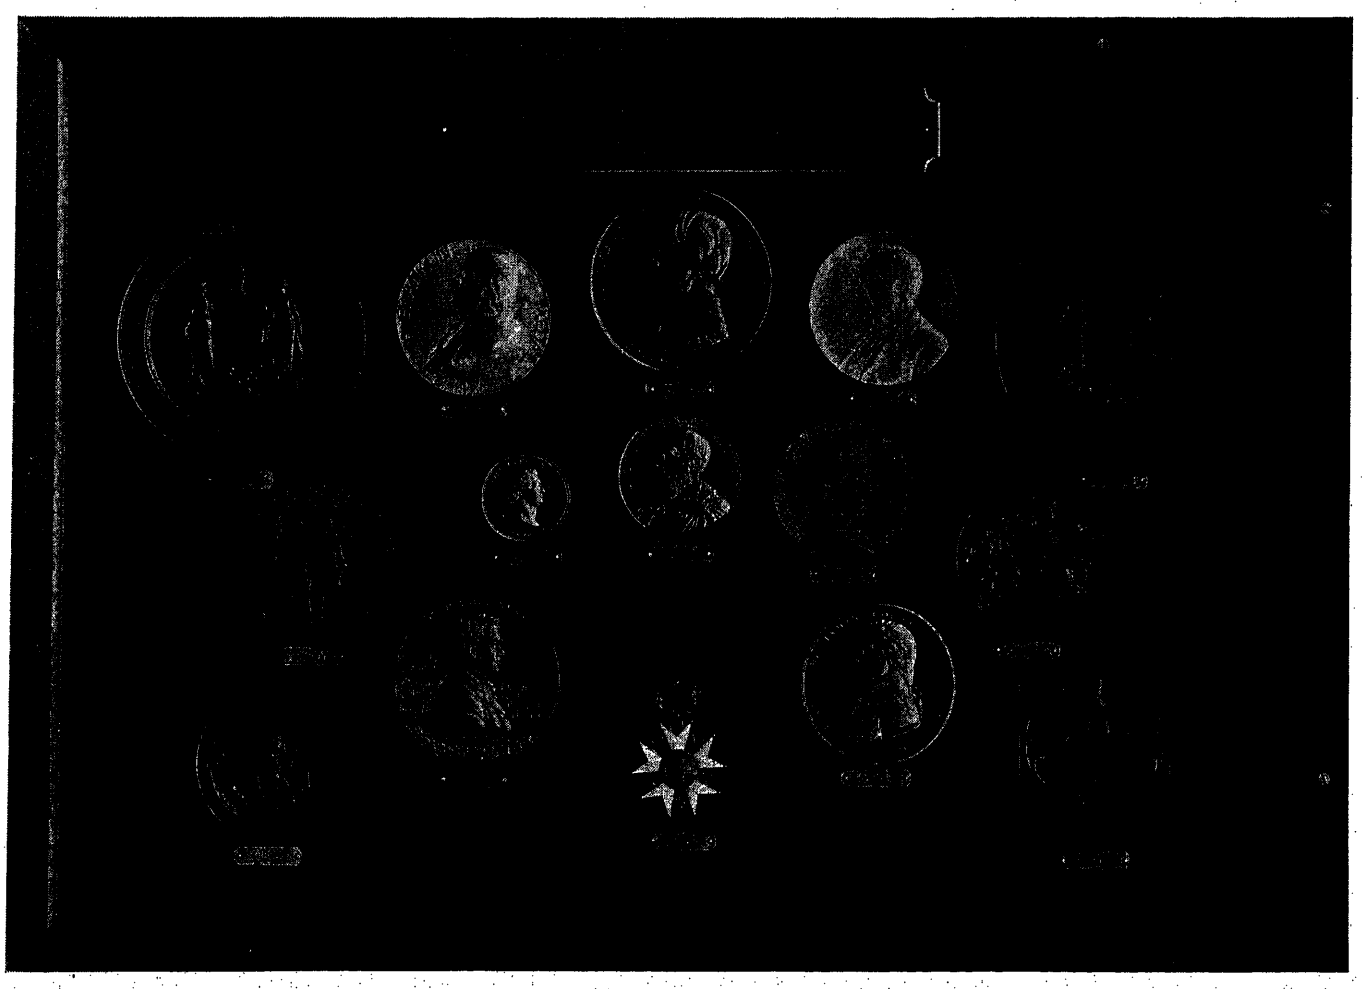
**Middle Eastern District Meeting**
Akron, Ohio, Fall 1937

cated to the public, because no patent or invention dealing with public safety should be restricted or made unavailable for general use.

### Developments on the Transformer

In the further development of a-c machinery, he invented the constant-current transformer and the induction regulator, in which a movable secondary or primary coil could be adjusted automatically to give constant-current output. For the purpose of increasing the power capacity of transformers, he proposed in 1887–89 the use of oil for cooling and for insulation purposes, and further called attention to the deleterious effect of moisture in the oil.

### Resistance Welding—Repulsion Motor



One of the most important of Thomson's contributions to industry was his discovery of the principles and development of the resistance process of electric welding, whereby the welded surfaces were fused and united by the heat produced by the resistance in the contact between them. Although Elihu Thomson was not the first to utilize the electric arc in welding, the fundamental Demeritens patent was bought by the Thomson Electric Welding Company on Thomson's advice and, had arc welding developed within the life of the patent, that company would have controlled the arc- as well as the resistance-welding art.

Another of Thomson's most fundamental discoveries was the principle of dynamic repulsion between a primary and a secondary coil, which he demonstrated by simple experiments. A vertical iron core was wound with a coil through which an alternating current could be passed. The core projected above the coil into a jar of water. Fitting loosely around the core was a second small coil, free to slip up and down the core in the water, and supporting by its terminals an incandescent lamp. When an alternating current was sent through the primary coil, a current was induced in the movable secondary coil, which lighted the lamp and at the same time raised the coil against the force of gravity high up in the jar of water. This scientific observation subsequently was developed by Thomson into an a-c repulsion motor.

### Meters—High-Frequency Apparatus

During the years 1885–95 Doctor Thomson was busily engaged in the development of electric meters, especially recording wattmeters. For his wattmeter he was awarded the Grand Prix of the Paris Exposition at a competition held after the exposition in 1889.

As early as 1890, and continuing intensively for several years thereafter, he conducted a series of experiments on high-

Bottom row (left to right): First Prize, Trans-Mississippi Exposition, Omaha, Nebr. 1898; Edison Medal, 1909; Legion D'Honneur, officier et chevalier, 1889; Rumford Medal, for electric welding and lighting, 1901; and Grand Prize, Louisiana Purchase Exposition, 1904

A gold medal was awarded to Doctor Thomson at the Columbian Exposition, in 1893, by certificate of award, but no medal was received; he also received in 1935 the medal of the Verein Deutscher Ingenieure, which is not shown here

frequency alternating currents, building the foundation for many of the developments in radio and other high-frequency applications in use today. He constructed one of the first high-frequency dynamos, if not the first; a machine operating at frequencies of from 30 to 40 times as great as any previously built. In conjunction, he designed some of the earliest high-frequency transformers. While Thomson was working in this field he discovered a method of producing alternating currents of still higher frequencies from a d-c arc by shunting the arc with inductance and capacitance. This interesting method of producing alternating currents later was applied to radiotelegraphy by Poulsen, and therefore is generally known as the Poulsen arc. Thomson also discovered that the insulating power of oils at these high frequencies is much greater than at ordinary commercial frequencies, if the insulating power is measured in terms of the path through which the arc passes.

Incidentally, Thomson is credited with having discovered the principle of the tuned electric circuit, and with having been the first to use the method in electrical communication. This was done very early in his career, while he was still a professor at Central High School, in performing some experiments in wireless signaling that preceded the famous experiments of Hertz by about 12 years.

Immediately following the announcement of the discovery of Roentgen rays, Doctor Thomson began a series of experiments and developments in connection with X rays. The foundation for this work had been laid by his previous experiments on electrical discharges through gases at low pressures, and led to the first application of stereoscopic methods in X-ray technology only one year after Roentgen rays themselves had been announced. This work led to various practical improvements in the design of X-ray tubes. Thomson also took an interest in the physiological effects of X rays.

Elihu Thomson also was active outside the domains of electrical research. Working with Houston, while they were at Central High School, he perfected his centrifugal machine for the separation of liquids of different densities, the forerunner of the widely used cream separator and the laboratory and commercial centrifuge. He also devised the fluid-pressure engine and the fused-quartz mirror for astronomical telescopes. In his own name he held more than 700 American patents.

### Thomson the Man

In his private life as a citizen, as well as an inventor, Elihu Thomson endeared himself to his neighbors and his fellow workmen and always was considered to be a wise counselor in civic affairs. Even outside his laboratories he was always engaged in some research project as a hobby. A lifetime hobby was astronomy, in which he was active as an amateur from an early age. He also was interested in microscopes, color photography, and in building and playing pipe organs. He had a host of friends, not only in the United States, but also in Europe.

His aspect of life is characterized by his own words "No greater joy has come to me than the joy of accomplishment. Then too, I have had the satisfaction of aiding in giving employment to large numbers of intelligent men and women."

Doctor Thomson was a member of many organizations in addition to those that had awarded him honorary memberships, including:

1. American Academy of Arts and Sciences (fellow and member of the Rumford committee)
2. American Association for the Advancement of Science (fellow)
3. American Astronomical Society (member)
4. American Chemical Society (life member)
5. American Electrochemical Society (member)
6. American Mathematical Society (member)
7. American Optical Society (member)
8. American Philosophical Society (fellow and past-president; also a past member of the council)
9. American Physical Society (fellow and life member)
10. Pi Gamma Mu, national science honorary society (life member)
11. British Association for the Advancement of Science (life member)
12. Engineers' Club of London, England
13. Société Française des Electriciens (member)
14. Commercial and Merchants Club of Boston, Mass. (member and past-president)
15. Engineers' Club of Boston (life member)
16. Boston Press Club (life member)

and 22 other societies and clubs of local, national, and international character.

Doctor Thomson was particularly interested in educational work. His vast store of experience and knowledge always was at the disposal of his younger, less experienced associates, among whom he was noted for his ability to explain the most abstruse subjects in simple, understandable language. He was affectionately known to them as "the Professor," a simple "friendly" title that he strongly preferred in spite of his many degrees. He was a life member of the Corporation of Massachusetts Institute of Technology, a member of the executive committee of the corporation, and twice served as its acting president.

For many of its most fundamental contributions—technical, ethical, and humanistic—the profession of electrical engineering is indebted to Elihu Thomson.

### Thomson as Seen By Some Institute Leaders

**Arthur E. Kennelly,** president 1898–1900—I had the privilege of knowing the late Professor Thomson for many years. He was endowed with great abilities as an engineer, inventor, researcher, and teacher. His special fields of work were in applied physics, chemistry, and mechanics. He was a pioneer in electric power transmission and distribution, as well as in electric welding, an art which he founded and highly developed. He was an excellent designer and constructor of electric machinery and apparatus. Many of the machines and instruments used in the early days of the electric power industry were constructed under his design and superintendence. At one time he constructed a 25-centimeter telescope, lenses and all, with his own hands. He introduced and developed the existing prevalent types of electric motor-driven energy meters, registering in kilowatt-hours.

He was a tireless scientific worker from early boyhood. At 17 years of age he was assistant professor of chemistry and at 22 was professor of chemistry in the Central High School of Philadelphia, where, in his leisure time, he made important inventions in electric power transmission.

He never allowed any of his time to be wasted. His was a kindly, engaging, and stimulating, personality. As a leader in electrical engineering he was admired and esteemed by thousands.

**Charles F. Scott,** president 1902–03—As I recall Professor Thomson, several specific incidents come to mind, trivial perhaps, but characteristic.

One afternoon some 12 or 13 years ago we had been in conference in Boston on some committee matter and found ourselves with a couple of hours to spare. We strolled about the city as he led the way to some particular photographic shops, in his search for films for color photography in which he took great interest. I was never more impressed with the great simplicity and ease of his manner and conversation.

To me, Professor Thomson always was a great electrical pioneer. Later I had met him, principally in AIEE activities. But, in strolling with him through the streets of Boston, I realized that my once mystical hero was very human; in simple companionship, he even insisted on accompanying me to my place of departure.

On the occasion of the celebration of his eightieth anniversary held in 1933 at Massachusetts Institute of Technology, I asked him what it was at the centennial exposition in Philadelphia in 1876 that aroused his interest in electricity. Immediately a smile came over his face and with a twinkle in his eye he said, "I will tell you. There was a Gramme dynamo there from France which operated one arc lamp, and there was another dynamo for electroplating, and another which lighted the lamp on the top of the building." This memory meant a great deal to him as it later on shaped his whole career.

He told me also an interesting incident "The Rhumkorff coil uses a low-voltage current for producing a very high voltage. I wondered if the process could be reversed and the high voltage current in the fine winding would produce a current in the heavy winding. I was fearful of the results and put off the experiments until I had a coil of my own. I placed the ends of the heavy terminals close together and observed carefully when the Leyden jars were discharged through the fine wire coil. There was a flash and when I attempted to separate the terminals I found them solidly welded together. That was the beginning of my work in electric welding."

His curiosity, his readiness to experiment, his observation, and his practical deductions from his experiments were the beginning of a new art.

And it seems to me that these qualities of simplicity and modesty, and his following along the lines prompted by his curiosity and interest, indicate qualities which were inherent in the man and have influenced his whole career.

**Dugald C. Jackson,** president 1910–11—Elihu Thomson was great as an engineer, as a scientist, and as a citizen; and in each

category he has received deservedly high recognition. I first met him when he was 35 years old and I was 21, and the impression of his fascinating enthusiasm for the development of electrical engineering and his fertile approach to difficult problems of experimental science has never left me. It has seemed to me that those qualities in Thomson have equally stirred others and led to the wish to honor him that has been displayed internationally.

Being, by intellectual nature, a great inventor, Thomson directed his qualities into human service, and the world is indebted extraordinarily to him for his productions. At least one of his original inventions, electric welding, has become a great industry of itself as well as contributing advantages to many industries. Numerous others of his productions have widely influenced industry and contributed to human comfort. The death of Thomson takes a great man from electrical engineering and a great citizen from the nation.

**Gano Dunn,** president 1911–12—Elihu Thomson's magnificent scientific and engineering accomplishments have made history. To me his personal influences was as great as his intellectual influence. He always had in mind the inventor, the engineer, the student, as well as the invention, the design and the study. This will forever cause him to be rated as one of our greatest teachers as well as one of our greatest engineers and scientists.

It was to him I early owed recognition that all engineering, notwithstanding its tremendous economic involvements, rests inseparably upon science. His lectures and papers were marvels of exposition. A talk with Elihu Thomson invariably stimulated thought and fired ambition.

His methods of work and qualities of character formed the careers and won the undying affection of large numbers of the generation of engineers who now mourn his loss.

**Frank B. Jewett,** president 1922–23—Appraisal of Elihu Thomson and his contributions to the advancement of electrical engineering in the light and power field can best be made by those who were his close associates in the many sectors of it which were enriched by his scholarly mind.

Outside the field of our common interest in the welfare of the American Institute of Electrical Engineers, in which our association commenced, my long and close friendship with Dr. Thomson has hardly been involved with things electrical. It has been concerned mainly with matters of general scientific interest and in the problems which came to us as fellow members of the Corporation of Massachusetts Institute of Technology.

Above all other things, however, it has been as an esteemed friend that I have known, admired, and loved Doctor Thomson. His versatile and cultured mind, his simplicity, and his joy in the simple worth-while things of life, which did not diminish with the years, made him a friend to be cherished.

Quite outside the boundaries of his professional life, his death will deprive the world of one of its choice spirits.

**H. P. Charlesworth,** president 1932–33—Doctor Thomson's investigations and inventions contributed enormously to the advance of all the engineering arts. However, his contributions went further than these individual activities. In addition to publishing his results and methods, his enthusiasm and technique were passed on to hundreds of engineers, first as a professor, later as a director of the laboratories which bear his name, and finally as a great leader in his profession. His fruitfulness was shared with others whom he had trained and inspired. His whole life was indeed in accord with and greatly contributed to the highest ideals of the engineering profession. It is not surprising, therefore, that his name is among the illustrious group who were the charter members of the American Institute of Electrical Engineers which ever is endeavoring to perpetuate these high ideals.

**A. M. MacCutcheon,** president 1936–37—One of my greatest regrets is that I did not have the privilege of a close personal acquaintance with Doctor Elihu Thomson, but I am fortunate in having met him. His writings have been an inspiration to me even as far back as my student days.

His deductions, his inventions, and his achievements form a cornerstone in the theoretical structure which represents the engineering knowledge of our time.

His modesty, his cheerful optimism, his breadth of vision, his clear thinking, and his indomitable spirit formed a pattern which all engineers may well emulate.

He was a charter member of the American Institute of Electrical Engineers and its fifth president. We who have followed in his footsteps, looked upon him as an inspiration, a valued counselor, a guiding light.

Elihu Thomson in his laboratory, studying the heavens through his telescope. Astronomy was his life-long hobby

### Elihu Thomson as Seen By Some Industrial Associates

**Owen D. Young,** chairman, General Electric Company—Mr. Thomson was one of the few great pioneers in the electrical field who had the rare good fortune to see his vision become a reality and to receive the appreciation of a justly grateful world for his contribution to the health and happiness of people everywhere. The General Electric Company was always proud of his intimate association with it.

**Willis R. Whitney,** vice-president, General Electric Company—Professor Thomson was one of the leaders who helped in the estab-

lishment of the Northeastern Section of the American Chemical Society back in '97 or '98. We New England chemists knew him as an expert in our field, just as the electrical engineers recognized him as pre-eminent in their field, and the mechanical engineers as a leader in theirs. Astronomers also knew that he was of their group. He was an all-round scientist.

When the General Electric Company offered me the research work at Schenectady, I was in doubt as to my fitness and as to the quality of the opportunity until I hurriedly consulted "the Professor." He was very kind, as always, and was quite clear that the opportunity offered me was a great one. So I owe a large part of the satisfactions I have enjoyed during the past 36 years to Professor Thomson's kindly interest. Through those years my admiration and affection for him steadily increased, and in his death I feel a great personal loss.

**Gerard Swope,** president, General Electric Company—Since the very beginning, Professor Thomson was associated with the General Electric Company and its predecessor bearing his name, the Thomson-Houston Company. His accomplishments for these companies and many others throughout the world bearing his name and for the entire electrical industry were many and conspicuous.

His interest in research, his enthusiasm for new ideas, and the advancement of young engineers continued almost to the day of his passing. His memory will long be cherished by those who knew him, and he leaves a fine tradition and inspiration for those who follow him.

**William D. Coolidge,** director, General Electric Research Laboratory—In the death of Professor Thomson, the General Electric Company has suffered a great loss. Its earliest products were for the most part the offspring of his brain. Great in engineering and invention, he played a most important rôle in the early development of the electrical art. He was a pioneer in arc lighting, was the father of electric welding, devised the first commercial recording wattmeter, and produced by the score the various devices needed for making electric generation and distribution reliable and safe.

He was a true scientist, and by example and precept established the tradition of scientific research in the General Electric Company. When the research laboratory of the company was founded, he served on its advisory council, and, by his experience, wisdom, and fertility in ideas, was of great help to the laboratory in its early years.

His breadth of knowledge, mental alertness, and originality made association with him delightful and stimulating, while his kindliness and simple sincerity won the affection of all who knew him. I was privileged to know him well, and I feel the loss of a great and good friend.

**Karl T. Compton,** president, Massachusetts Institute of Technology—In his own character and in his great achievements he was one of the truly great men of his century. In all the years of his interest in the Institute [MIT], he displayed a loyal and active faith in the social values of technological education.

Professor Thomson's loss to this institution and all others would be irreparable were it not for the fact that his nobility of character will remain as a lasting inspiration, and his scientific achievements will continue permanently to confer immeasurable benefits to the world.

## Lightning Reference Book To Be Issued Soon

Culminating more than 2 years of work carried on by the lightning and insulator subcommittee of the AIEE power transmission and distribution committee, the AIEE Lightning Reference Book is scheduled to be issued in July.

Lightning and its effect upon electric power systems and apparatus have been under investigation for more than 20 years during which many articles of interest and value have been published in the technical literature. Heretofore this extensive literature has been available principally only through library research. Now, recognizing the value of a conveniently bound volume containing the full reproductions of texts, illustrations, and tabulations of all important material that has been published on the subject of lightning, the subcommittee has completed the selection of just such material for just such a handy reference volume.

The Lightning Reference Book will be about the size of the current annual volumes of AIEE TRANSACTIONS and similarly bound in durable green cloth. It will contain some 1,550 pages, 8½ by 11 inches in size, in which will be reproduced in full some 230 technical papers and articles selected by the subcommittee from the technical press of the past 18 years for their important and practical utility to all those in any way interested in the study of, or the protection against, lightning

A comprehensive subject and author index will facilitate the ready reference use of the volume and, for those who may wish to carry their pursuit further, 200 additional technical papers and articles of a supplemental nature not included in the volume will be fully covered in the indexes.

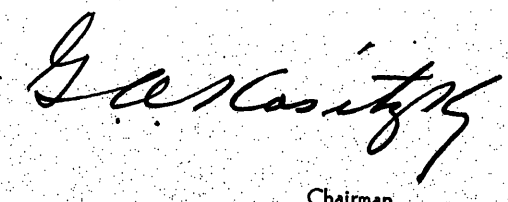
The announced price of the Lightning Reference Book is $6.00 to members and $7.50 to nonmembers, plus postage in either case (10 pounds shipping weight).

### ADVANCE ORDERS REQUIRED

A limited edition only will be issued. The actual number of volumes to be published will be governed by the number of advance orders on file at AIEE headquarters, 33 West 39th Street, New York, N. Y. by May 15, 1937 (with reasonable allowance for overseas mail).

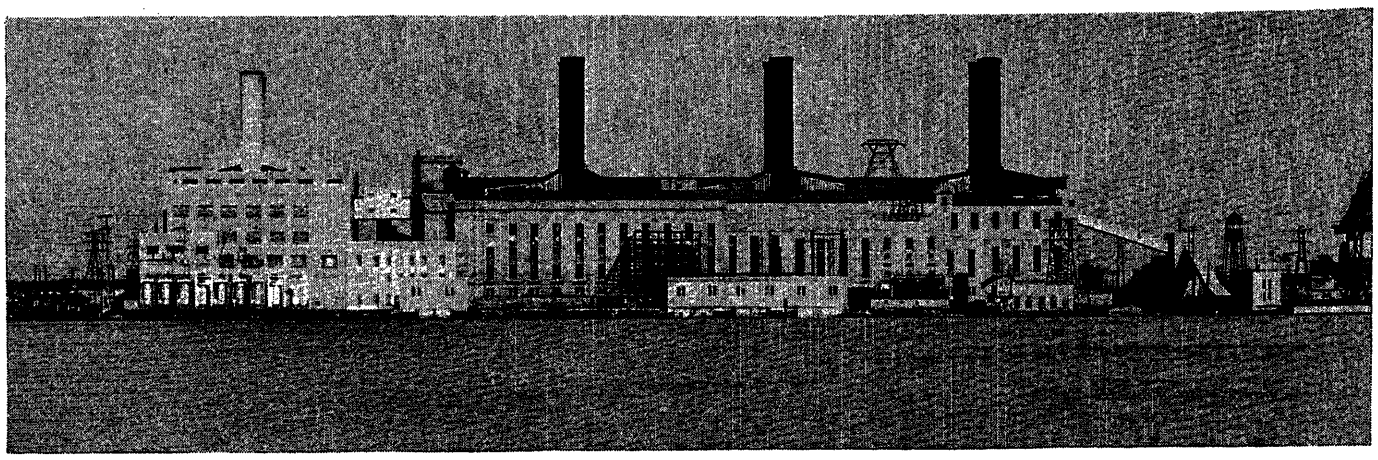
The several hundred advance orders that have been on file the past year have made possible the prosecution of this project to successful conclusion with publication now imminent. All persons wishing to increase standing orders, or to place orders, must do so immediately to be assured of receiving the volume.

Further details and a convenient order coupon are given on page 4 of the advertising section of this issue.



## Membership—

Mr. Institute Member:



Have you finished reading that recently distributed pamphlet entitled "Membership in the American Institute of Electrical Engineers"? It does a fine job of sketching the activities of the Institute—don't you agree?

Please do not forget to pass it along to some non-member who is eligible for membership. Also, if you can interest him in becoming a member, recommend him by using the stamped and addressed card furnished with the pamphlet. He will receive application blanks and necessary information promptly.

Your Membership Committee thanks you sincerely for the very good co-operation you have given it throughout the year. With your continuous service, we shall surely reach our goal of twenty-five per cent more applications than last year.

Chairman
National Membership Committee

Huntley stations of the Buffalo General Electric Company

# North Eastern District Meeting and Student Branch Convention

THE annual meeting of the North Eastern District of the AIEE and student Branch convention will be held in Buffalo, N. Y., from Wednesday to Friday, May 5–7, 1937. The meeting headquarters will be in the Hotel Statler. Buffalo "the gateway to the west" with its many diversified industries makes an ideal convention city and the local committee has taken full advantage of the situation and arranged a very attractive program. Thus there is a trip to the new $22,000,000 hot and cold strip mill of the Bethlehem Steel Company, Huntley stations 1 and 2, some of the hydroelectric stations at Niagara Falls, the Ford Motor Company's plant, and several of the other industries, not to mention a very attractive trip for the ladies, including the marvelous spectacle of Niagara and its color illumination. Entertainment has been arranged for the evenings and men prominent in Institute affairs are on the program. Registration will take place in the Hotel Statler from 9:00 a.m., Wednesday, May 5.

### Technical Sessions

The opening session will consist of an address of welcome by A. C. Stevens, Institute vice-president for the North Eastern District, which will be followed by a series of papers of outstanding interest to all who are connected with the central station industry. These papers include the latest information in the field of lightning investigations on transmission lines, the application of automatic oscillography, operating performance, research, and testing.

On Thursday, May 6, a general session will be held at 9:30 a.m. which will be opened with a greeting by President MacCutcheon. This session will feature conductor vibration studies illustrated by motion pictures, surveying telephone service requirements, and design trends in steel mill electrification. In the afternoon the electrical features of the new Bethlehem 72-inch strip mill will be described by F. D. Egan and his talk will be followed by a trip to the plant. On Thursday morning a student technical session will be held at which papers will be presented by the students.

**Table I—Hotel Rates**

| Hotel and Location | Room Capacity | Single | | Double | | Twin |
|---|---|---|---|---|---|---|
| | | Without Bath | With Bath | Without Bath | With Bath | |
| Arlington, 136 Exchange | 150 | $1.50 | $2.00 up | $2.50 up | $3.50 up | $4.00 up |
| Buffalo, Swan and Washington | 450 | | 2.00 up | | 4.00 up | 4.50 up |
| Fairfax, 715 Delaware | 400 | | 2.50 up | | 4.50 up | 5.50 up |
| Fillmore, 207 Delaware | 60 | | 1.75 up | | 3.00 up | 3.50 up |
| Ford, Delaware and Cary | 750 | 1.50 up | 1.50 up | 2.50 up | 3.00 to 4.00 | 3.25 to 4.00 |
| Graystone, Johnson Park | 150 | 1.50 up | 2.00 up | 2.50 up | 3.00 up | 3.00 up |
| Lafayette, Lafayette Square | 420 | | 2.50 up | | 4.50 up | 4.50 up |

| Statler, Niagara Square | 1,100 | | 3.00 up | | 5.00 up | 6.00 up |
| Stuyvesant, 245 Elmwood | 450 | | 2.00 up | | 3.00 up | 4.00 up |
| Touraine, Delaware | 300 | 1.75 | 2.00 up | 3.00 up sharing bath | 3.50 up | 4.50 up |
| Westbrook | 312 | | 2.50 up | | 4.00 up | 6.00 up twin 3-room suite |

On Wednesday evening a talk and demonstration on "Fiber Glass" will be given by L. W. W. Morrow, general manager of the fiber glass department of the Corning Glass Works. All who know Mr. Morrow and his ability to give an interesting talk will look forward to a very enjoyable evening. On Thursday evening directly following the informal dinner another very instructive, interesting talk and demonstration will be given. The subject will be "Kodachrome Colored Film" by L. D. Mannes, co-inventor, of the Eastman Kodak Company. After the lectures dancing also may be enjoyed in the hotel.

### Women's Entertainment

In addition to the foregoing entertainment the following has been specially arranged for the women guests of the Institute. Buffalo is a large, smartly metropolitan city, possessing beautiful parks and suburban areas.

**Wednesday, May 5**

A trip to the incomparable Niagara Falls. Leaving at 11:00 a.m., the party will cross the Peace Bridge and drive down the beautiful Canadian Boulevard. After luncheon, there will be an inspection trip of the Falls and the Niagara Rapids, followed by dinner in the modern General Brock Hotel, from the roof garden of which can be seen another interesting view of the cataract. At 8:00 p.m. the illumination takes place and to see the mighty waterfall in the play of clear and colored lights is a sight never to be forgotten.

**Thursday, May 6**

A luncheon at the Hotel Statler, followed by a fashion show presented by one of Buffalo's smartest shops.

### Inspection Trips

Buffalo and its environs have over 500 diversified industries. The committee has

## Program

Daylight Saving Time

For the papers that have been published in ELECTRICAL ENGINEERING reference to the issue and page is given.

### Wednesday, May 5

**9:00 a.m.—Registration**

**10:00 a.m.—Opening Session**

Address of Welcome, A. C. Stevens, vice-president, North Eastern District, AIEE.

LIGHTNING CURRENTS IN 132-KV LINES, Philip Sporn and I. W. Gross, American Gas & Electric Company. February, pages 245–52, 259–60

PROBABLE OUTAGES OF SHIELDED TRANSMISSION LINES, S. K. Waldorf, Pennsylvania Water & Power Company. Scheduled for May issue

SPECIAL USES FOR THE AUTOMATIC OSCILLOGRAPH, G. A. Powell and R. E. Walsh, New York Power & Light Corporation. April, pages 438–40, 476–7

**2:00 p.m.—General Session**

*THE OPERATING PERFORMANCE OF VARIOUS RELAY APPLICATIONS, George Steeb and L. J. Audlin, Buffalo, Niagara, and Eastern Power Corporation.

*THE OPERATING PERFORMANCE OF HUNTLEY STEAM STATION, J. M. Geiger (electrical) and Donald Scranton (mechanical), Buffalo General Electric Company.

*RESEARCH AND TESTING IN A LARGE ELECTRIC UTILITY, (*A*) by W. F. Davidson, Brooklyn Edison Company, Inc., and (*B*) by W. P. Dobson, Hydro Electric Power Commission of Ontario.

**8:00 p.m.—Talk and Demonstration**

FIBER GLASS, L. W. W. Morrow, Corning Glass Works.

### Thursday, May 6

**9:30 a.m.—General Session**

Greeting, A. M. MacCutcheon, president AIEE.

*EXPERIMENTAL STUDY OF DANCING CABLES, D. C. Stewart, Buffalo, Niagara and Eastern Power Corporation. Illustrated by motion pictures of dancing when the cable was coated with water to simulate an ice formation.

*SURVEYING TELEPHONE SERVICE REQUIREMENTS FOR LARGE USERS, R. E. Corey, New York Telephone Company.

*DESIGN TRENDS IN STEEL MILL ELECTRIFICATION, L. A. Umansky, General Electric Company.

**2:00 p.m.—Special Address**

ELECTRICAL APPLICATION—BETHLEHEM 72-INCH STRIP MILL, F. D. Egan, Bethlehem Steel Company.

**3:00 p.m.—Inspection Trip**

Bethlehem Steel Company's 72-inch new strip mill. Note: Number limited and women are excluded. Everyone must arrive by bus in the party and cameras are prohibited. Nominal charge for busses to and from the hotel.

**7:00 p.m.—Informal Dinner**

**8:30 p.m.—Talk and Demonstration**

KODACHROME COLORED FILM, L. D. Mannes, co-inventor, Eastman Kodak Company.

### Friday, May 7

**9:30 a.m.—Student Technical Session**

**2:00 p.m.—Inspection Trip**

Huntley stations No. 1 and No. 2 of the Buffalo General Electric Company; number will be limited and a nominal charge will be made for busses to and from the hotel.

* These papers are scheduled for presentation, but they have not been accepted for publication at the time of going to press.

judiciously selected the following trips, some of which are optional in the short time available.

**1. Bethlehem Steel Company's New $22,000,000 Hot and Cold Strip Mill**

The number to be accommodated is of necessity limited and all people must arrive by bus with the party, which will not include any ladies. Anyone arriving by private car will not be admitted. The carrying of cameras or taking pictures is not permitted. Nominal charge for busses to and from the hotel.

**2. Huntley Stations No. 1 and No. 2 of the Buffalo General Electric Company**

The number is of necessity limited. Nominal charge for busses to and from the hotel.

**3. Other Trips of Interest.**

The number which can be accommodated on some of them is of necessity limited.

*A.* Niagara Falls Power Company—(1) Adams and Schoellkopf stations; (2) Harper and Gibson substations.

*B.* Distribution system of Buffalo General Electric Company (Network and Automatics).

*C.* Local plants of New York Telephone Company.

*D.* Variable-ratio frequency changer at Lockport, N. Y.

*E.* Spaulding Fiber plant, Military Road.

*F.* Remington Rand plants.

*G.* Albright Art Gallery.

*H.* Ford Motor Company's plant.

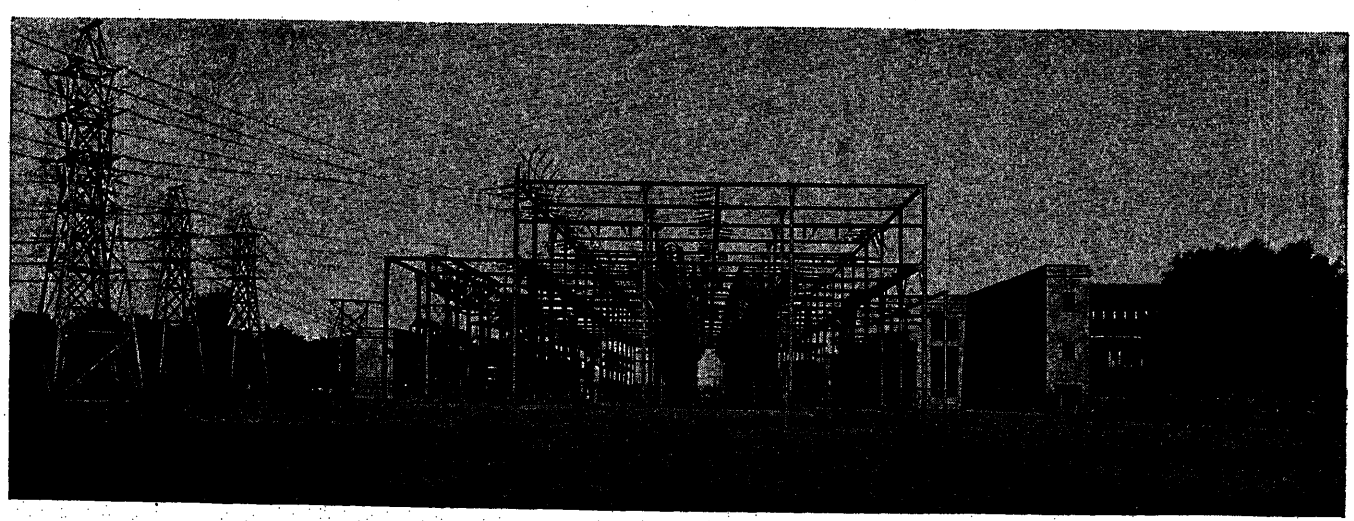
*I.* Modern broadcasting.

*J.* Museum of Science.

Industrial plants near Buffalo include:

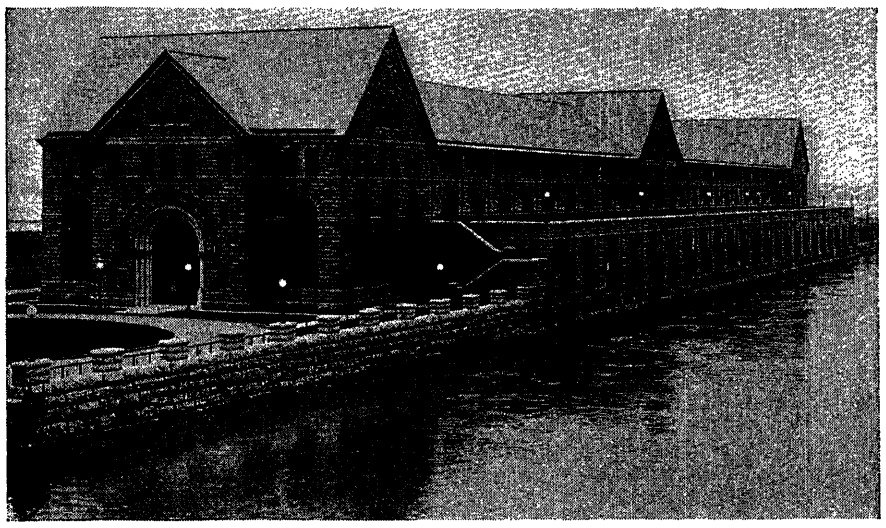
Lapp Insulator Company at LeRoy, N. Y.—50 miles

Porcelain Insulator Company at Lima, N. Y.—65 miles



Corning Glass Company at Corning, N. Y.—125 miles

SPORTS



Golfing in this region is not usually much of a sport until along about Decoration Day. However, weather permitting, the committee will be very glad to furnish the necessary cards so that anyone wishing to play can do so at any course in western New York State.

REGISTRATION

Members who plan to attend the meeting should register in advance by mail. Advance registrations should be sent to George M. Pollard, chairman, registration com-

Harper substation of the Niagara Falls Power Company

Adams station of the Niagara Falls Power Company at Niagara Falls, N. Y.

mittee, Buffalo General Electric Company, 39 East Genesee St., Buffalo, N. Y. Registrations should be completed on arrival at headquarters in the Hotel Statler. A registration fee of $2 will be charged all nonmembers except Enrolled Students and the immediate families of members.

### Hotels

Members should make room reservations by writing directly to the hotel of their preference. For convenience the rates of the headquarters hotel, the Statler, as well as the rates of a number of the other hotels are listed in table I.

### Rules on Presenting and Discussing Papers

At the technical sessions, papers may be presented in abstract, 10 minutes being allowed for each paper unless otherwise arranged or the presiding officer meets with the authors preceding the session to arrange the order of presentation and allotment of time for papers and discussion.

Any member is free to discuss any paper when the meeting is thrown open for general discussion. Usually 5 minutes is allowed to each discusser for the discussion of a single paper or of several papers on the same general subject. When a member signifies his desire to discuss several papers not dealing with the same general subject, he may be permitted to have a somewhat longer time.

It is preferable that a member who wishes to discuss a paper give his name in advance to the presiding officer of the session at which the paper is to be presented. Each discusser is to step to the front of the room and announce, so that all may hear, his name and professional affiliations. Three typewritten copies of discussion prepared in advance should be left with the presiding officer.

Other discussions to be considered for publication should be typewritten (double spaced) and submitted in triplicate to C. S. Rich, secretary of the technical program committee, AIEE headquarters, 33 West 39th St., New York, N. Y., on or before May 21, 1937. Discussion of addresses and papers which is not for publication need not be submitted for consideration.

### Committees

**District Meeting Committee:** A. C. Stevens, vice-president, North Eastern District, *chairman;* R. G. Lorraine, secretary-treasurer, North Eastern District, *secretary;* F. N. Tompkins, *chairman,* committee on student activities, North Eastern District; N. E. Brown, R. F. Chamberlain, C. L. Dawes, E. D. Lynch, K. B. McEachron, and J. L. Scanlon.

**General Committee:** E. S. Bundy, *chairman;* T. J. Brosnan, R. T. Henry, Cromwell McIntosh, and H. M. Sharp.

**Program Committee:** R. W. Graham, *chairman;* J. F. Oehler and T. O. Zittel.

**Registration Committee:** G. M. Pollard, *chairman;* J. N. Ewart and J. M. Pfohl.

**Ladies Committee:** Miss Laura Rischman, *chairman;* Miss Muryle Baker, Miss Nora Haun, and Miss Maryon Ingham.

**Dinner Committee:** D. C. West, *chairman;* E. A. Brown, H. L. Randall, and T. J. Woth.

**Inspection Committee:** George Eighmy, *chairman;* C. H. Lockwood and H. L. Townend.

**Publicity Committee:** N. A. Brown, *chairman;* A. D. Gibson and W. J. Thompson.

**Transportation:** Clair Gaylord, *chairman;* E. J. Rahill and W. J. Schnautz.

**Printing:** Melvin Brown, *chairman;* F. L. West and G. A. Zehr.

## Canadian Engineers to Celebrate Semicentennial

The Engineering Institute of Canada is planning to celebrate its fiftieth anniversary at a semicentennial meeting to be opened in Montreal on June 15, 1937. The organization, which was formed in 1889 as the Canadian Society of Civil Engineers, now embraces the professional interests of engineers of all branches. There are some 4,500 members, including over 400 outside of Canada.

It is desired that the anniversary meeting may be the means of bringing about closer acquaintances between engineers in the United States and Canada. The principal functions of the meeting are to be in the Windsor Hotel, June 15 to 17 inclusive. Further information may be obtained from the headquarters of the organization at 2050 Mansfield Street, Montreal.

## AIEE Summer Convention Features of General Interest

Internationally known industrial plants in the Milwaukee metropolitan area will open their gates to convention visitors during the AIEE summer convention, to be held in Milwaukee, Wis., June 21–25, 1937, with headquarters in the Schroeder Hotel. Trips through a number of such plants are being arranged by the inspection trips committee, of which S. H. Mortensen of Milwaukee is chairman.

Present plans call for the holding of technical sessions of the convention in the mornings, leaving the afternoons free for special inspection tours, sightseeing trips, and sports. The inspection trips are being planned with the view of providing interesting diversion as well as technical and scientific information.

### Convention Sessions

Tentative arrangements are being made to hold 10 technical sessions and 1 general session designed to interest a great many members. This session will be in 2 parts, which will not be in parallel with any of the other sessions, to permit general attendance. The first part will consist of an address by a prominent speaker, which will have to do with engineering and economics. The second part of the session will consist of a discussion of the topic "how can institute programs be made of greatest value to the membership." The subject will be introduced by men invited to prepare brief statements by the special committee on Institute activities. The 10 technical sessions are as follows: electrical machinery, power transmission, vibration and balance, education, instruments and measurements, protective devices, general power applications (control), selected subjects, research, and production and application of light. The program will be further broadened by technical conferences on other subjects which will be arranged later.

### Inspection Trips

Among the large industrial firms with whom inspection visits have tentatively been arranged are the following:

**Allis-Chalmers Manufacturing Company; power, electrical, industrial, and agricultural equipment.**

**A. O. Smith Corporation; automobile frames and parts, welded pipe, pressure vessels, glass-lined storage tanks, and steel barrels.**

**Harnischfeger Corporation; large cranes, hoists, and excavators, and electric welders.**

**Globe Union, Inc.; storage batteries, radios, and roller skates.**

**Joseph Schlitz Brewing Company; beer.**

**Milwaukee Electric Railway and Light Company; as announced in the February issue of Electrical Engineering, opportunity will also be provided for a trip through the new Port Washington power plant. This station holds the world record for economy of operation in steam generating stations, having generated 382,868,218 net kilowatt-hours in 1936, with an average coal consumption of 10,954 Btu per kilowatt-hour.**

# National and District Prizes Available for Technical Papers

ALL members and Enrolled Students who have presented papers at Institute meetings, as stipulated and otherwise in accordance with the following "Conditions of Awards," are eligible under rules adopted by the board of directors for one or more of the established national and District prizes.

These rules have recently been revised by actions of the board of directors. A new prize in each of the geographical Districts, to be known as "the District prize for graduate paper" has been established. In the future the award of this prize as well as the national and District prizes for Branch paper will be on the basis of presentation during the academic (college) year, July 1 to June 30, inclusive, rather than on the basis of presentations during the calendar year.

Excerpts of the rules as revised fully describing each prize and stating the conditions of awards, when and where the papers should be submitted for consideration, are given in the following paragraphs. However, the changes in these rules explained in the preceding paragraph are not to be applied retroactively and they do not pertain to the 1936 papers now under consideration. The winners of every prize will each receive a certificate of award but by action of the board of directors the only cash award for 1936 papers will be $25 for the "District prize for Branch paper" in each geographical District. When papers are written jointly the cash awards shall be divided and a certificate shall be issued to each author.

## National Prizes

### Conditions of Awards

1. The national best paper prize in each of the 3 classes namely, engineering practice, theory and research, and public relations and education, may be awarded for the best original paper presented at any national, District, or Section meeting of the Institute, provided the author, or at least one of coauthors, is a member of the Institute.

2. The national prize for initial paper may be awarded for the most worthy paper presented at any national, District, Section, or Branch meeting of the Institute, provided the author or authors have never previously presented a paper which has been accepted by the technical program committee, and the author, or at least one of coauthors, is a member of the Institute or is a graduate student enrolled as a Student of the Institute.

3. The national prize for Branch paper may be awarded for the best paper based upon undergraduate work presented at a Branch or other Student meeting of the Institute, provided the author or authors are Enrolled Students of the Institute.

For the national best paper prize and the national prize for initial paper, only papers presented during the calendar year shall be considered except those for the best paper prize in the class of public relations and education. In this class all papers presented subsequent to those considered at the time of the last previous award in this field and prior to the end of the last calendar year will receive consideration. For the national prize for Branch papers only papers presented during the preceding academic (college) year, July 1 to June 30, inclusive, shall be considered.

### Papers Must Be Submitted

All papers approved by the technical program committee which were presented at the national conventions or District meetings will be considered for the best paper prizes and initial paper prize without being formally offered for competition. All other papers which were presented at Section, Branch, or Student meetings must be submitted in triplicate with written communications to the national secretary on or before February 15 of the following year, stating when and where the papers were presented. This may be done by authors, by officers of the Institute, or by the executive committees of Sections or geographical Districts.

### Basis of Grading Papers

The valuations which shall govern the grading of papers for purposes of making awards shall be as follows:

**Analysis of Subject**.....10 per cent
The paper shall present a clear outline of the situation out of which arises the need for the preparation of a paper on the particular subject, explaining the point of view assumed in the presentation.

**Logical Presentation**.....10 per cent
The presentation should include an analysis of the difficulties encountered, the methods of attack, and the solution of the problem.

**Originality**.....10 per cent
Credit should be given to the paper which brings to its subject matter a fresh point of view, a healthy openmindedness, or a discarding of some outworn traditions.

**Unity**.....10 per cent
While brevity and conciseness are important they should not be attained at the sacrifice of unity and completeness of presentation.

**Value in Its Field**.....30 per cent
The value of the paper as a contribution to the literature in its own field should receive particular consideration.

**Value to Electrical Engineering**.....30 per cent
The paper should be considered from the standpoint of the quality of its contribution to the advancement of electrical engineering and its value to civilization.

### Publication

Papers awarded prizes shall be published in full or in abstract, in Electrical Engineering, in the Transactions, or in pamphlet form.

## District Prizes

### Conditions of Awards

1. The District prize for best paper may be awarded for the best paper presented at a national, District, or Section meeting, provided the author, or at least one of coauthors, is a member of the Institute.

2. The District prize for initial paper may be awarded for the most worthy paper presented at a national, District, Section, or Branch meeting, provided the author or authors have never previously presented a paper before a national, District, Section, or Branch meeting of the Institute, and the author, or at least one of coauthors, is a member of the Institute or is a graduate student enrolled as a Student of the Institute.

3. The District prize for Branch paper may be awarded for the best paper based upon undergraduate work presented at a Branch or other Student meeting of the Institute, provided the author or authors are Enrolled Students of the Institute.

4. The District prize for graduate paper may be awarded for the best paper based upon graduate work and presented at a national, District, Section, or Branch meeting of the Institute. At the time of presentation, the author must be a graduate student and either a member or an Enrolled Student of the Institute. In the case of coauthors, the graduate requirement applies to all and the membership requirement applies to at least one of the coauthors.

Each District prize may be awarded only to an author who, or to coauthors of whom at least one, is located within the District, and for a paper presented at a meeting held within, or under the auspices of the District.

### Papers Must Be Submitted

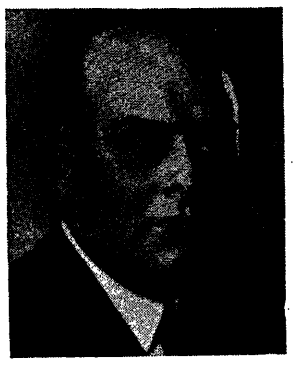
Only papers presented during the calendar year shall be considered for the prize for best paper and for initial paper. Only papers presented during the preceding academic (college) year, July 1 to June 30, inclusive, shall be considered for the prize for Branch paper and for graduate student paper. They must be submitted in duplicate by authors, or by officers of the Section, Branch, or District concerned to the District secretary on or before the following dates: best paper and initial paper, February 15; Branch paper and graduate student paper, July 15.

### Committees on Awards

All the District prizes for a given calendar year shall be awarded prior to May 1 of the succeeding year by the District executive committee or by a committee appointed by the District executive committee and authorized to make such awards.

### Basis of Grading Papers

The valuations which shall govern the grading of papers for purposes of making awards shall be the same as those for the national prizes but the papers will not be graded by the technical committees.



**Four New Groups Join ASA.** Sixty national organizations are now affiliated with the American Standards Association according to an announcement of Dana D. Barnum, president. The 4 new groups affiliated since January 1, 1937, are Automobile Manufacturers Association, Brick Manufacturers Association of America, American Society of Heating and Ventilating Engineers, and Structural Clay Products, Inc.

## In Memoriam

ON THE thirtieth day of January 1937, the Institute suffered a serious loss in the death of Edward Barnard Meyer, who had, only 6 months previously, completed his term as its forty-eighth president, and who had long been one of its most loyal and active members.

Doctor Meyer was graduated from the Newark Technical School in 1901 and from Pratt Institute in 1903. He was immediately employed by the Public Service Electric and Gas Company of New Jersey as an engineering assistant, and remained with it and its subsidiaries until 1922, rising steadily to higher positions, and being assistant chief engineer during the last 3 years. In 1922, he was appointed chief engineer of the Public Service Production Company, which was formed at that time, and, in 1929, was promoted to vice-president. Upon the merger of that company, in 1930, with the United Engineers and Constructors, Inc., he was made vice-president of the latter and executive and engineering head of its Newark office. In 1935, he returned to the Public Service Electric and Gas Company as chief engineer of the electric engineering department.

Doctor Meyer joined the Institute in 1905, and was transferred to the grade of Member in 1913 and to the grade of Fellow in 1927. He was a director 1927–31, a vice-president 1932–34, and president 1935–36. He served as chairman of many of the Institute's most important committees, as a member of others, and as an Institute representative upon numerous joint organizations. He was chairman of the New York Section 1926–27.

E. B. MEYER

The Newark College of Engineering awarded him the honorary degree of doctor of engineering in 1936.

Doctor Meyer's ability as an engineer, his constant adherence to the highest ideals, his patient and persistent efforts to encourage co-operation, and the breadth and thoroughness of his consideration of all matters connected with his duties gave him an outstanding position of leadership in his chosen profession.

RESOLVED: That the executive committee of the American Institute of Electrical Engineers hereby expresses, upon behalf of the membership, its deepest regret at the death of Doctor Meyer, and its most sincere appreciation of his unusually large number of important contributions to the conduct and development of Institute activities, and be it further

RESOLVED: That these resolutions be entered in the minutes and transmitted to his family. —AIEE Executive Committee March 25, 1937

## To Institute Members Planning Trips Abroad

Members of the Institute who contemplate visiting foreign countries are reminded that since 1912 the Institute has had reciprocal arrangements with a number of foreign engineering societies for the exchange of visiting member privileges, which entitle members of the Institute while abroad to membership privileges in these societies for a period of 3 months and members of foreign societies visiting the United States to the privileges of Institute membership for a like period of time, upon presentation of proper credentials. A form of certificate which serves as credentials from the Institute to the foreign societies for the use of Institute members desiring to avail themselves of these exchange privileges may be obtained upon application to Institute headquarters, New York. The members should specify which country or countries they expect to visit, so that the proper number of certificates may be provided, one certificate being addressed to only one society.

The societies with which these reciprocal arrangements have been established and are still in effect are: Institution of Electrical Engineers (Great Britain), Société Française des Electriciens (France), Association Suisse des Electriciens (Switzerland), Associazione Elettrotecnica Italiana (Italy) Koninklijk Instituut van Ingeniurs (Holland), Verband Deutscher Elektrotechniker E. V. (Germany), Norsk Elektroteknisk Forening (Norway), Svenska Teknologforeningen(Sweden), Stowarzyszenie Elektrykow Polskich (Poland), Elektrotechnicky Svaz Ceskoslovensky (Czechoslovakia), The Institition of Engineers, Australia (Australia), Denki Gakkwai (Japan), and South African Institute of Electrical Engineers (South Africa).

## Middle Eastern District Executive Committee Meets

A meeting of the executive committee of the Institute's Middle Eastern District was held in Pittsburgh, Pa., October 27, 1936. Circumstances have prevented reporting this meeting in an earlier issue. The meeting was attended by the following:

W. H. Harrison, vice-president, AIEE
H. A. Dambly, secretary, Middle Eastern District
H. H. Schroeder, chairman, Akron Section
H. L. Brouse, secretary, Akron Section,
A. O. Austin, Akron Section
J. H. Lampe, secretary, Baltimore Section
O. C. Schlemmer, secretary, Cincinnati Section
W. E. Wickenden, chairman, Cleveland Section
E. E. Kimberly, chairman, Columbus Section
W. D. Bearce, secretary, Erie Section
G. E. Northup, chairman, Lehigh Valley Section
O. C. Traver, chairman, Philadelphia Section
Paul Frederick, secretary, Pittsburgh Section
R. L. Dunlap, director, Pittsburgh Section
T. H. Frankenberry, Sharon Section
W. A. VanWie, Toledo Section
G. G. Coleman, Washington Section
E. O. Lange, chairman, District committee on student activities, Drexel Institute, Philadelphia

Vice-President Harrison, who presided, first discussed briefly the objectives and status of the efforts of the Institute's membership committee. A general discussion of membership activities of the Sections

**Electronics Program.** A special lecture and conference program in electronics will be held in Ann Arbor, Mich., as a part of the 1937 summer session of the University of Michigan, with the co-operation of members of the technical staffs of the General Electric Company, Westinghouse Electric and Manufacturing Company, Radio Corporation of America, and Bell Telephone Laboratories, Inc. The primary objective will be to provide an opportunity for teachers and prospective teachers of electronics, engineers and physicists engaged in electronic development work in industry, and graduate students interested in electronics to broaden and unify their grasp of fundamental electronic principles. Lectures will be given by Doctors Saul Dushman (A'13) and Lewi Tonks of General Electric, Doctors H. E. Mendenhall and F. B. Llewellyn of Bell Telephone Laboratories, Doctors Joseph Slepian (A'17, F'27) and R. C. Mason (A'26) of Westinghouse, Doctor V. K. Zworykin (M'22) and B. J. Thompson of RCA, and Professors L. B Loeb of the University of California and W. G. Dow (A'19, M'32) of the University of Michigan. A special bulletin describing the details of the program will be mailed to anyone interested upon request to Professor W. G. Dow, electrical engineering department, University of Michigan, Ann Arbor.

**Medal for Papers on Welding.** The board of directors of The American Welding Society has accepted a gold medal to be known as the Lincoln Gold Medal, to be presented to the author of the best paper on any phase of welding published in the *Journal* of The American Welding Society during the year October 1936 to October 1937. The medal was offered by J. F. Lincoln (A'08, M'20) president of the Lincoln Electric Company, Cleveland, Ohio. Papers to be considered must be received by the editor of the *Journal* before September 15, 1937.

throughout the District followed. At the conclusion of this discussion, the report of the District prize paper committee was presented; appointment of a prize paper committee for 1936–37 was deferred.

Student conferences and conventions was the next subject discussed. The various delegates outlined briefly what is being done by their respective Sections and Branches. Vice-President Harrison urged the Sections to do all possible to assist and stimulate interest in technical schools. He called attention to the probable shortage of technically trained men in the years ahead. There was also an exchange of ideas pertaining to Section programs and activities.

To serve as the District co-ordinating committee for the year ending July 31, 1937, the following were selected: O. C. Schlemmer, W. C. Kalb (Cleveland Section), E. E. Kimberly, Paul Frederick, and E. O. Lange. The vice-president and District secretary are *ex-officio* members of this committee.

Vice-President Harrison reported that the proposed Akron (Ohio) District meeting had been approved by the Institute's board of directors on May 25, 1936. Although no definite date for the meeting was selected, early October was suggested. A. O. Austin and H. L. Brouse were designated as representatives of the Akron Section to serve on the committee for this meeting. These 2 members together with the District co-ordinating committee constitute the complete committee for this meeting.

A proposal to request that the Institute's 1938 summer convention be held at Pennsylvania State College was discussed in detail. Although the college is not within Institute Section territory, delegates of neighboring Sections indicated their willingness to assist. After lengthy discussion it was voted unanimously that the executive committee of the Middle Eastern District recommend that consideration be given to Pennsylvania State College for a summer convention or District meeting in 1938. (After considering this and other invitations for the 1938 summer convention the Institute's board of directors voted at its meeting of January 25, 1937, to hold the 1938 summer convention at Washington, D. C.)

**French Congress on Lighting.** A congress on lighting is being arranged by a French committee to be held from June 24, 1937, to a date to be set early in July during the international exposition. American lighting men have been invited to attend and to participate in discussions on lighting matters. According to Preston S. Millar, president of the United States National Committee of the International Commission on Illumination, "This congress is not to be confused with the next meeting of the ICI scheduled for next year in Holland. The French lighting congress is to be held in connection with the international exposition. The United States National Committee of the ICI, however, is lending its support and will be glad to serve as a 'clearing house' for American lighting men desiring to present papers at the forthcoming congress on lighting in Paris." Inquiries relating to the subject should be addressed to Mr. Millar, in care of Electrical Testing Laboratories, 80th Street and East End Avenue, New York, N. Y.

## Springfield Section Offers Prizes for New Ideas

In an effort to develop "ways and means to advance and improve the Springfield Section of the AIEE," that Section announced at its March 12 meeting that for the best papers on that subject submitted within the ensuing 6 months, cash prizes of $25 for the best and $10 for the next best paper would be awarded at the Section's October or November meeting. All members of the Springfield Section (national, local, and student) except present Section officers, present chairmen and vice-chairmen of Section standing committees, and members of the Section's prize paper contest committee, are eligible to enter the contest.

Papers submitted are specified to be between 500 and 2,500 words in length, and subject to grading on the following basis:

*Clarity of Presentation.* The paper shall give a clear presentation of the merits of proposed changes and/or any defects in present practices..20 per cent

*Originality.* The paper should include new ideas for the management and activities of the Section, that will make it more interesting and of greater benefit to the largest number of members. It should bring to its subject matter a fresh point of view, a healthy open-mindedness, and/or a discarding of any outworn traditions.....30 per cent

*Value to the Section.* The improvements and benefits, estimated to result from adopting the ideas presented in the paper will receive particular consideration.....50 per cent

## Great Lakes District Executive Committee Meets

The annual meeting of the executive committee of the Institute's Great Lakes District was held at Chicago, Ill., on November 16, 1936. Circumstances have prevented reporting this meeting in an earlier issue. The following members of the committee were present:

C. F. Harding, vice-president, AIEE
A. G. Dewars, secretary, Great Lakes District
F. L. Stanley, chairman, Central Indiana Section
Burke Smith, chairman, Chicago Section
J. A. Fitts, secretary, Chicago Section
S. S. Attwood, chairman, Detroit-Ann Arbor Section
D. H. Hanson, chairman, Fort Wayne Section
C. S. Allen, secretary, Fort Wayne Section
F. H. McClain, chairman, Iowa Section
R. R. Benedict, chairman, Madison Section
W. A. Kuehlthau, secretary, Madison Section
J. A. Potts, chairman, Milwaukee Section
J. H. Kuhlmann, chairman, Minnesota Section
C. H. Nelson, secretary, Minnesota Section
H. J. Reich, chairman, Urbana Section
K. A. Auty, treasurer, District executive committee

K. L. Hansen of Milwaukee, chairman of the 1937 summer convention committee, was present by invitation.

Vice-President Harding presided. Following the presentation of the treasurer's report, Mr. Auty was re-elected treasurer for the ensuing year. The following were chosen to serve on the District co-ordinating committee for the ensuing year: Burke Smith, R. R. Benedict, F. L. Stanley, and J. A. Potts; these, together with Vice-President Harding and District Secretary Dewars, who serve as *ex-officio* members, constitute the complete committee.

Concerning the Institute's 1937 summer convention to be held in Milwaukee, Wis., June 21–25, K. L. Hansen reported that the various committees had been active and were already well along on their way toward completion of their plans. He called attention to the proposal to include on the program a paper, or papers, on economic or social subjects and asked the opinion of the members of the District executive committee on this matter. Vice-President Harding had mentioned at the opening of the meeting that the Institute's board of directors had considered the general question of broadening Institute activities to include discussions on social and economic subjects, at its meeting of October 20, 1936. After considerable discussion, a committee was appointed to prepare a resolution expressing the attitude of the District executive committee on the general subject of including papers of this type on convention programs. At the close of the meeting, this committee, which consisted of F. L. Stanley, D. H. Hanson, and Burke Smith, offered the following resolution:

"Resolved, That the executive committee of the Great Lakes District hereby goes on record as endorsing the action taken by the board of directors of the American Institute of Electrical Engineers at its meeting on October 20, 1936, in which it favored broadening of the scope of papers for national presentation and publication, to include topics of economic and sociological interest to the profession."

The resolution was adopted and the secretary was instructed to forward a copy to the Institute's board of directors.

Reports were presented by the various Section delegates, in which the activities of the respective Sections during the preceding year were described, and plans for the coming year outlined. Practically all of the Sections represented reported an increase in membership during the preceding year.

## Medals Awarded for Public Service

Two awards of the American Institute of the City of New York for 1937—a gold medal to the Bell Telephone Laboratories, New York, N. Y., and a fellowship to Watson Davis, director of Science Service, Washington D. C.—were announced December 28, 1936, by Dr. Gerald Wendt, director of the organization, and presented February 4, 1937.

The gold medal, given annually by the organization in recognition of outstanding accomplishment in research, was awarded to the Bell Telephone Laboratories "for researches in electrical science which, applied to communication, have promoted understanding, security, and commerce among peoples by transmitting human thought instantly throughout the world."

One of the pioneer industrial organizations for scientific research, Dr. Wendt said, the Bell Telephone Laboratories developed and perfected many of the valuable means of modern communication. Its outstanding achievements have been in the development of the instrumentalities on which are based a nation-wide system of communication. The award was received in the name of the more than 4,000

men and women of the Laboratories by its president, Dr. F. B. Jewett (A'03, F'12, past-president).

The fellowship, conferred for "outstanding service in the interpretation of science to laymen," was awarded to Watson Davis "for interpreting to the people of the Nation the rapid progress of science upon which modern civilization depends, and for the organized dissemination of research findings as news."

Mr. Davis is director of Science Service, a pioneer organization in the interpretation and dissemination of the news of science. He is well known as author and editor of books on scientific subjects including "The Story of Copper", "Science Today," and "The Advance of Science." His articles, appearing regularly in newspapers, magazines, and technical journals, bring science to the people in the language of the layman.

The council on awards of the American Institute of the City of New York consists of: M. L. Crossley (chairman) Calco Chemical Co.; Oscar Riddle, Carnegie Institution, Station for Experimental Evolution; W. D. Coolidge (A'10, F'24) General Electric Co.; W. H. Carrier, Carrier Engineering Corp.; Oliver Kamm, Parke Davis & Co.; Ward F. Davison (A'14, F'26) Brooklyn Edison Co.; L. O. Kunkel, Rockefeller Institute for Medical Research; Clinton J. Davisson, Bell Telephone Laboratories; and Harden F. Taylor, Atlantic Coast Fisheries.

The American Institute of the City of New York was incorporated in 1828 for the purpose of "encouraging and promoting domestic industry in this State and in the United States." Its membership includes leading scientists and others interested in promoting this aim. Its work among school children, including its "science congress," "Christmas lectures," and "children's science fair," is notable.

## Production of Electricity in 1936 Breaks All Records

PRELIMINARY figures on the total production of electricity for public use in the United States in 1936, as given by the Federal Power Commission, indicate a total output of 113,473,000,000 kilowatt-hours, which is an increase of 14 per cent over that for 1935, the year of the previous maximum.

The production of electricity by the use of water power was about 40,893,000,000 kilowatt-hours, or 2 per cent more than in 1935, and amounted to 36 per cent of the total, whereas the average for the 16-year period, 1920 to 1935, was 36.9 per cent of the total. The percentage for 1936 indicates that despite the abnormal conditions experienced in the drought-stricken states the production of electricity by the use of water power is maintaining its relative position with respect to other sources of power.

The preliminary data indicate that the fuel rate for 1936 was about 1.45 pounds per kilowatt-hour as compared with 1.46 pounds per kilowatt-hour in 1935. Following the former procedure of the U.S. Geological Survey, the fuel rate was calculated by converting the oil and gas used in the production of electricity into equivalent tons of coal and dividing the total coal used in producing electricity and coal equivalent of the gas and oil used by the corresponding output. This method does not allow for the variation in Btu content of the gas and oil as fired, and includes the output of both steam and internal combustion engines, and is therefore only approximate.

An analysis of all steam plants using coal exclusively for fuel indicates that the coal rate is 1.49 pounds per kilowatt-hour. Since these data include coal used in plants held in reserve and operated intermittently, it is not representative of good practice. Some of the more efficient plants are producing a kilowatt-hour with approximately 0.8 pound of coal at the present time.

The accompanying tables show for the United States and its divisions the annual production of electricity for public use by use of water power and by the use of fuels for the years of 1935 and 1936 and the percentage change from 1935 to 1936 in the production of electricity and in the use of different fuels in generating electricity. The information is preliminary and is based on the figures of production of electricity in the monthly reports during 1936. The output of central stations, both publicly and privately owned, electric railway plants, plants operated by steam railroads generating electricity for traction, and U.S. Bureau of Reclamation plants and that part of the output of manufacturing plants which is sold are included in these data. Accurate data are received each month representing approximately 98 per cent of the total output shown; the remaining 2 per cent of the output is estimated so that the data represent 100 per cent of the generation.

A final report, which will give totals for each state for 1936 and include final revisions of previously published data, will be published in April 1937; copies may be obtained by application to the Federal Power Commission, Washington, D. C.

### Annual Production of Electricity for Public Use in the United States, 1935 and 1936

| | Production of Electricity—Millions of Kilowatt-Hours | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | Total | | | By Use of Water Power | | | By Use of Fuel | | |

## John Scott Awards for 1937 Presented

Doctors W. D. Coolidge (A'10, F'34) and Irving Langmuir, director and associate director respectively of the research laboratory of the General Electric Company in Schenectady, N. Y., and Doctor Evarts A. Graham of the school of medicine of Washington University in St. Louis, Mo., were recipients of the John Scott awards for 1937 granted by the City Trusts of the City of Philadelphia and presented at a recent dinner of the American Philosophical Society. With each award went a certificate, a copper medal, and $1,000 in cash. Doctor Coolidge accepted the award for Doctor Langmuir in the latter's absence.

The award to Doctor Coolidge was based on his application of a new principle in X-ray tubes; to Doctor Langmuir for his physical and chemical discoveries resulting in improved gas-filled incandescent lamps; and to Doctor Graham for his application of the X ray to the study and diagnosis of gall-bladder conditions.

In making the presentations, Ernest I. Trigg, chairman of the Board of City Trusts, explained that history had made but scant recordings of John Scott, the donor of the fund, and his reason for bequeathing to the City of Philadelphia in 1816 the sum of $4,000, the income from which was to be "laid out in premiums to be distributed among ingenious men and women who make useful inventions."

It was originally stipulated that no award was to carry a cash premium of more than $20 and the medal was to be inscribed "To the most deserving."

History reveals that John Scott was a chemist in Edinburgh, Scotland, but just why he chose Philadelphia for his grant is a mystery. It is thought his attention had been drawn to the city either through the American Philosophical Society or his admiration of Benjamin Franklin whom he may have met when Franklin visited Scotland in 1769. When the fund was taken over by the Board of City Trusts, the principal had grown to $21,000 and in 1917, or 100 years after the original grant, it amounted to $100,000. At this time the board appealed to the courts and received permission to increase the amount of the awards to a maximum value of $2,000, but none has been for any amount greater than $1,000.

In the period between 1920 and 1937 inclusive, 73 awards were made to outstanding scientists and inventors in all parts of the world, including Japan, Holland, England, France, Italy, and South America. Recipients have included Madam Curie, Reginald A. Fessenden, Orville Wright, Lee De Forest (A'04, F'18), Thomas A. Edison (A'84, M'84, HM'29, past vice-president, deceased '33), Guglielmo Marconi (HM'17), Samuel M. Vauclain, W. L. R. Emmet (A'93, M'94, HM'33, past vice-president, member for life), Nikola Tesla (A'88, F'17, member for life), Charles F. Kettering (A'04, F'14), and Edward G. Budd.

## $100,000 Edison Memorial Gift of W. S. Barstow

The Edison Pioneers, composed of early associates of Thomas Alva Edison, met February 11, 1937, in New York, N. Y., to observe the ninetieth anniversary of Edison's birth. At that meeting, it was announced that a 135-foot concrete tower surmounted by a huge electric-light bulb would be erected in Edison's memory during the summer of 1937 on the site of his early laboratory at Menlo Park, N. J. The tower, which will cost more than $100,000, will be the gift of W. S. Barstow (A'94, F'12) retiring president of the Edison Pioneers. (Mr. Barstow served the AIEE as a manager in 1900–03, and as a vice-president in 1903–05.) Mr. Barstow specified that the gift was to the Thomas Alva Edison Foundation in the name of the Edison Pioneers.

The Thomas Alva Edison Foundation was conceived jointly by the Edison Pioneers and the AIEE, with the approval of the Edison family, and was incorporated in 1935. Its purpose is to carry out plans to perpetuate recognition of the world's progress emanating from the inventor's efforts. The construction of this memorial tower constitutes one phase of the Foundation's program.

It is planned to build a concrete tower around the skeleton steel tower which was erected in 1929, 2 years before Edison's death. The light which will be at the top is that which is now at the top of the steel structure. It is a bulb-like light composed of more than 900 incandescent lamps, and will be enclosed in prismatic glass. Edison turned it on from Dearborn, Mich., on October 21, 1929, during the national celebration of the fiftieth anniversary of his invention of the incandescent electric light. It has burned every night since and will not be extinguished during the construction of the new tower.

## Electrical Vocabulary Prepared by IEC

The International Electrotechnical Commission plans publication of the first edition of its "International Vocabulary" in 1937. This work, undertaken soon after the St. Louis Electrical Congress in 1904, contains some 2,000 scientific and industrial terms used in the various branches of electrotechnics. It is the result of many years of continuous effort by a committee of experts including delegates from Austria, France, Germany, Great Britain, Italy, the Netherlands, Poland, Spain, and the United States.

Definitions appear in English and French, the 2 official languages of the IEC, and a translation of terms is given in German, Italian, Spanish, and Esperanto. While the committee developing this international vocabulary appreciates that it does not constitute a complete unification of electrotechnical nomenclature, through periodic review and revision based on the constructive criticism of electrical authorities throughout the world it should become increasingly valuable to engineers.

The edition will be limited, and copies at about $2.50 each may be reserved by writing to the United States National Committee of the International Electrotechnical Commission, 29 West 39th Street, New York, N. Y.

**Electrical Treatment of Air.** A new technical subcommittee on the treatment of air with electricity, formed under the committee on research of the American Society of Heating and Ventilating Engineers, recently held its first meeting to plan a research program directed toward discovering, if possible, and duplicating in indoor conditioned air, certain intangible qualities that seem to give outdoor air a particular zest and life. Discussion at the meeting included the problem of ozonization, ionization, and treatment of air with ultraviolet rays, which has shown possibilities in the killing of air-borne disease germs, and the subject of electrical filtering of air by precipitation processes. Members of the subcommittee include L. W. Chubb (A'09, F'21, past director) director of research laboratories of Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., and Vannevar Bush (A'15, F'24) vice-president and dean of engineering at Massachusetts Institute of Technology, Cambridge.

# American Engineering Council

## Council Acts on Patent Situation

In all the flurry of patent legislation in recent years, Council's patents committee has kept closely in touch with the situation and has acted in the interest of engineers and the public where opportunity was found to improve patent-court conditions and patent-office procedure. Of most importance are actions taken on the proposed court of patent appeals and legislation affecting pooling and cross-licensing.

The committee has recommended that Council support legislation for a single court of patent appeals, and the AEC assembly has approved the recommendation and has taken the position that it will look with favor upon the idea of having the judges named to such court selected by the President and confirmed by the Senate only after careful review of their special and technical competence with the advice of engineering and scientific societies as well as the advice of the patent bar and the legal profession.

Scientific advisers to the courts have been recommended by a number of agencies, but not all with the same purpose. Most often quoted is the suggestion of a special patents committee of the Science Advisory Board. That committee recommended that scientific advisers be made available to aid *trial* court justices. In this conclusion, the committee agrees with the recommendations of the special patents committee of the Science Advisory Board. The patents committee looks with some favor on such an idea if a suitable method of selecting advisers free from preconceived opinions were fixed and if a sufficiently diversified list of skilled scientific and engineering talent were made available. However, the committee has doubted the wisdom of having such scien-

tific advisers named permanently as a part of a new single court of patent appeals. It feels that the idea of naming 3 such advisers who would serve for all classes of cases would not afford such highly skilled aid in all divisions of science and technology as courts really require.

The committee believes that the public interest has been much more served than harmed by patent pools and by cross-licensing. Such evils as may have been experienced would not have been corrected by any of the proposed forms of legislation. The committee believes that administration of present laws, including proper and reasonable application of antitrust legislation, would suffice to correct those types of evils of pooling that have been disclosed or charged as bad practice.

Council also has approved the patents committee's recommendation to oppose all the various types of proposals which would restrict the freedom of owners of patents to use them constructively under present laws. It regards such offenses as are now charged against the patent system as the result of defects in administration of present laws and not as evidence of the need of more legislation.

The committee believes that every effort should be made by industry as well as by the engineering profession to increase the presumption of validity of patents as issued. It feels that engineers generally should assist patent examiners whenever possible to keep abreast of the arts with respect to which they are examining patent applications. The committee has not found any legislation, proposed to date, sufficiently constructive to feel that it deserves support of AEC. It does, however, hope that some means may be developed for increasing the standards of competence and experience of the staff of examiners in the Patent Office.

The staff is following legislation for the court of patent appeals in *S.*475 introduced by Senator McAdoo of California, and the patents committee is giving further consideration to such matters as technical advisers to the courts, patent pooling and cross-licensing, compulsory working and licensing, automatic validation of patents 5 years after issue, and taxation during nonuse.

## AEC Unites Opinion On Rural Electrification

In its unbiased approach to the subject, Council's rural electrification committee seems to have made a real contribution toward a better understanding of the practical uses of electricity on the farm and toward a meeting of private and public minds on sound practices in rural electrification. The report of this committee's Report for 1936 was referred to by Morris L. Cooke, ex-administrator of REA, in a letter to the editor of the New York *Times* entitled "Rural Electrification" which was published in the February 1, 1937, issue of the *Times*. Mr. Cooke is also reported to have referred publicly to the report as representing an excellent approach to rural electrification.

Utilities and private industry also have sought copies of this report. All criticism received has been constructive and directed toward improving the recommendations for increasing the use of electricity on the farm and making the use pay dividends to the farmer in health, time-saving, and economy. Other suggestions concern ways and means to make rural distribution systems pay their own way, and the construction of rural lines of the lowest cost consistent with quality and service.

The AEC rural electrification committee made 5 recommendations with the ultimate well-being of citizens in rural life as the final objective: (1) every farmer who can use electricity economically should be supplied with it; (2) service should be supplied in the most efficient and dependable manner and at the lowest cost consistent with quality and service; (3) each farm operator should be informed as rapidly as possible regarding the electric-power and equipment needs of his own individual farm; (4) each farmer should be informed as rapidly as possible regarding the best ways of using this power and equipment so that the greatest economy may be effected; and (5) every effort should be made to develop new equipment and processes whereby electric power can be used to bring the farmer closer to his market, whether he is selling food products or the raw materials of industry.

In conclusion, the report advances the opinion that such a program of rural electrification will require the utmost co-operation between all branches of the agricultural and engineering professions, and all agencies, public and private, that are involved in this development. The problem is a tremendous one, but its solution will go so far in helping to solve the economic problems of American agriculture, and indirectly the economic problems of the nation, that it is worth the best efforts of all who have anything to contribute to it.

## Rural Electrification Administration Notes

Rural Electrification Administration news is the resignation of Administrator Morris L. Cooke. Mr. Cooke is reported to have resigned voluntarily to seek a rest from the burden of responsibility that the President drafted him to carry from the creation of the REA. An interesting rumor in connection with Mr. Cooke's resignation is the unofficial report that his friendly consideration of the interests of privately owned utilities added to the burden of his responsibility and engendered trying misunderstandings among his liberal colleagues.

John M. Carmody, an editor and industrial engineer, formerly a member of the National Labor Relations Board, chief engineer of CWA and FERA, with much experience in the railroad, steel, and coal industries and in private practice, succeeded Mr. Cooke. He is being assisted by Colonel George D. Babcock of North Carolina who was associated with Mr. Carmody in the other emergency agencies.

At the conclusion of Mr. Cooke's administration, REA had lent or ear-marked a total of more than $50,000,000 for 257 rural electric projects to serve 165,000 rural customers in 40 states and Alaska. These figures do not include funds involved in contracts providing that the Electric Home and Farm Authority co-operate with both public and private utilities in financing the sale of electric appliances for use by consumers located on public and private utility power lines.

# Engineering Foundation

## Doctor A. D. Flinn, Director of Foundation, Dead

Doctor Alfred Douglas Flinn, director of The Engineering Foundation, died March 14, 1937, at Scarsdale, N. Y., after a prolonged illness. He was born in New Berlin, Pa., August 4, 1869. He was graduated in 1893 from Worcester (Mass.) Polytechnic Institute, with the degree of bachelor of science in civil engineering, following which he took postgraduate work at the Massachusetts Institute of Technology, Cambridge. The University of Louvain, at its 500th anniversary celebration in 1927, conferred on him the degree of doctor of applied science, *honoris causa*. He received the honorary degree of doctor of engineering from Worcester Polytechnic Institute in 1932.

From 1894 to 1895, Doctor Flinn was employed successively by: Rice and Evans, civil engineers, of Boston, Mass.; Associated Factory Mutual Fire Insurance Companies, Boston; Waterworks Division of the Boston City Engineer's Office. From 1895 to 1902, he was engineer for the Massachusetts Metropolitan Waterworks, becoming principal assistant engineer. He served as managing editor of *The Engineering Record* (later combined with *The Engineering News*) 1902–04, following which he became general inspector for the Croton Aqueduct Commissioners, being in charge of their New York engineering office. In August 1905, he became associated with the Board of Water Supply of the City of New York, which he served until January 1918. He was successively division engineer, department engineer of headquarters, deputy chief engineer, and, on several occasions, acting chief engineer.

In January 1918, Doctor Flinn was named secretary of the United Engineering Society, which was succeeded by Engineering Foundation and United Engineering Trustees, joint agencies of the 4 Founder societies. He continued as secretary of United Engineering Trustees until June 23, 1934, and of The Engineering Foundation until his death. He became director of Foundation in 1922.

As secretary, or executive officer, of United Engineering Trustees, he supervised the Engineering Societies Building at 29 West 39th Street, executed and recorded the actions of the board of trustees, including administration of trusts and other funds, and rendered secretarial services to standing and special committees. After his resignation in 1934 he continued some special serv-

ices until the end of that year, when his engagement with the Trustees ended.

In co-operation with National Research Council, Doctor Flinn aided in developing and financing the Fatigue of Metals Research, the Arch Dam Investigation, the Alloys of Iron Research, and the Education Research Committee, including the pamphlet, "Engineering: A Career—A Culture." He also assisted smaller researches and the special research committees of the Founder societies and organizations co-operating with them.

He was instrumental, in conjunction with the National Research Council, in establishing the Personnel Research Federation, the Highway Research Board, and the American Bureau of Welding; and in conducting the Marine Piling Investigation, and the compilation of the Directory of Industrial Research Laboratories in the United States.

Doctor Flinn was assistant secretary of the John Fritz Medal Fund Corporation from 1920 to 1935. In February 1928, he was elected secretary and treasurer of the Daniel Guggenheim Medal Fund; he resigned as treasurer in May 1935, and relinquished his duties as secretary in May 1936.

He was a Fellow of the American Association for the Advancement of Science, and a member of the American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, American Mathematical Society, American Iron and Steel Institute, Sigma Xi, Sigma Alpha Epsilon, the Century Association, and the Engineers' Club. He was a past-president of the Municipal Engineers of the city of New York and holder of its gold medal for the best paper of the year. He was honorary foreign member of the section of engineering sciences of the Masaryk Academy of Prague, Austria, and a Knight of the Order of the White Lion, Republic of Czechoslovakia.

With R. S. Weston and C. L. Bogert, he compiled a "Waterworks Handbook," now in its third edition and extensively used in the United States and other countries. He originated and edited for 12 years the "Research Narratives" printed by the Engineering Foundation. He was also the author of many technical papers and chapters in technical books.

# Letters to the Editor

CONTRIBUTIONS to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or reject them entirely.

ALL letters submitted for consideration should be the original typewritten copy, double spaced. Any illustrations submitted should be in duplicate, one copy, to be an inked drawing but without lettering, and other to be lettered. Captions should be furnished for all illustrations.

STATEMENTS in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Short-Time Spark-Over of Gaps

*To the Editor:*

The paper "Short-Time Spark-Over of Gaps," by J. H. Hagenguth (ELECTRICAL ENGINEERING, volume 56, pages 67–76, January 1937) gives rise to several questions.

The curves *B* of figure 14 (page 74), showing the relations between breakdown voltage and time to breakdown of a 20-inch, rod gap for both positive and negative surges, cross in 2 places. No experimental points are shown on the curves—but if the author's estimates of from 10 to 20 per cent accuracy in determination of time to breakdown are accepted one might wonder if there is justification for showing 2 distinct curves. If the curves represent the physical picture correctly, the explanation for the negative surge breakdown time being both higher and lower than that for a positive surge, depending upon the magnitude of the overvoltage, might be that given below.

It will be noted that the minimum breakdown potential is always lower for a positive surge. The difference is small for suspension-insulator spark-over, amounts to 30 per cent in some cases for rod gaps. The fields at the 2 electrodes of the suspension insulator are probably nearly alike. However, because of the proximity of the ground plane the field at the grounded electrode of the rod gap is much less than at the ungrounded electrode. From simple sparking theory the sharper gradient at the cathode should give a lower breakdown potential.[1] Since the tests referred to in the paper are at high pressure, the theory of "electron avalanche" [2,3] must be invoked. The increase in gradient caused by the electron avalanche is in some cases only 14 per cent of the existing gradient.[4] The electron avalanche (with a lack of a positive source of electrons by illumination) might begin anywhere between the electrodes and reach its maximum value in the vicinity of the anode. Hence, for minimum breakdown potential the positive surge, with higher gradient at the ungrounded electrode due to both dissymmetry of the field and the electron-avalanche field, would be expected to give a lower breakdown voltage than a negative surge with only the dissymmetry of the field to give a high gradient.

In the case of overvoltage the problem is not quite the same, for we are dealing with the time required for breakdown. The potential gradient with either surge certainly will cause breakdown; it is only a question of how long a time before breakdown. On a statistical basis it might be expected that a negative surge will give a lower time to breakdown, for the electron avalanche certainly would have a considerable magnitude in the vicinity of the cathode, thus increasing the field at this point in a time shorter than that required for motion of the avalanche to the high field of the anode and the time for propagation of the secondary process of ionization to the cathode. These deductions are borne out in the tests involving a large distance between electrodes as shown in curves *A* and *B* figure 10, page 72, for intermediate overvoltages. (Note that the ordinates are per cent over voltage.) For the third case of very great overvoltage the times of breakdown should be about the same regardless of polarity of the surge, within the limits of the experimental error given by Hagenguth, as shown in figures 10 and 14.

The choice of definition of rate of voltage rise applied to surges given on page 71 seems consistent enough from examination of figure 9 and comparing it with figure 14. This brings up the method of measuring rate of rise of voltage for a voltage variation similar to figure 7*b* with an accentuated first rise. Here rate of rise would be smaller factor compared with the effect of 2 sudden voltage impulses. In standardizing a definition, or in expressing the results of tests, some limitation should be made on the magnitudes of a disturbing initial voltage pulse.

## Engineers and Government

*To the Editor:*

The engineering profession has, of late, been running the gamut of sharp criticism from those of the "more abundant life" diagnosticians who like to believe that we are the cold lobsters responsible for such economic nightmares as that from which the world is just awaking.

These pragmatists are convinced that we fiddled too much with logarithms and slide rules while the world burned in the fire of so-called technological unemployment, and that hereafter we should take it upon ourselves to pay as much attention to the efficiency of our economic apparatus as to the efficiency of our industrial and power-station equipment. Thus, they would have us practice not only engineering but also economics, sociology, finance, banking, and even black magic, and thereby distend ourselves into a legion of supermen, capable of designing skyscrapers and transformers for 40 hours a week and solving the problems of money and state in our off hours.

At first thought, the very audacity of the

proposal is flattering, but upon reflection it becomes apparent that the critics are indulging in the old game of passing the buck on to the geese that squawk the least. Engineers undoubtedly are less well organized than the members of other major professions, such as the medical and the legal and hence the little squawking that we do at times is perfunctory and in no way comparable to the unanimity of the 10,000,000-decibel squawk that comes from the throat of the American Medical Association, for instance, whenever it is pricked with a pin.

So that, far from swelling with pride at the suggestion that we must become a body of cure-all practitioners, we should, in the interest of tolerance, earnestly struggle against the natural impulse to laugh in our critics' faces. For the underlying weakness of their case lies in the fact that they almost wholly lack acquaintance with engineering problems and, typical of the clan of critics the world over, they find it far easier to stand without and grimace, and denounce the inner workings of a thing, than to take the trouble to learn something about what they are denouncing, and perhaps offer some constructive suggestions.

What they believe, no doubt, is that history and political science can be neatly and conveniently contained in a hypodermic syringe of some form, to be injected into the arm or leg of the student engineer at will, and in zero time. Because, if they have the slightest inkling of what they talk about, they must recognize the fact that the engineering school curriculum of 4 years falls far short of supplying the student with even adequate engineering training, and that at least another 2 years would be necessary to fulfill this primary requisite. They should know, too, that anything less than 6 years special study in the social sciences is wholly inadequate, and if they can add 6 and 6, they might get 12. Now 12 years of organized study, besides tending to create academicians and school teachers, is an expensive proposition, and such a course would leave the engineering profession open to rich men only (which, in itself, might not be a bad ideal). Further, the field of inquiry of pure engineering is so intricate and broad that only the best minds available can cope with it in a reasonably intelligent manner, and any scheme that calls for a mind able to cope with it, plus the problems of 4 or 5 other professional groups that can't even handle their own, is sheer nonsense, and unworthy of even the third-rate politicians who voiced it.

This is not to say that we, as a profession, are totally disinterested in society's problems. On the contrary, it is my belief that the engineer, in general, has a keener appreciation of the issues involved than have any other professional groups, and we would be more than happy to assist the nation's statesmen in their work. But the trouble is that politicians take to sound advice in precisely the same manner that a gagging infant takes to cod liver oil. Past experience has demonstrated amply the inadvisability of administering counsel in any but infinitesimal doses, and the chances are about $n$ to 1 against the lawmaker digesting even those.

Very truly yours,

RICHARD B. KAUFMAN (A'35)
54 Wendell Avenue,
Pittsfield, Mass.

## Wave Forms in Frequency-Tripling Transformers

*To the Editor:*

In the July 1936 issue of ELECTRICAL ENGINEERING the paper "Frequency Tripling Transformers," by J. L. Cantwell, shows the characteristics of one method of frequency tripling. The purpose of this letter is to show oscillograms of the wave forms of voltages and currents in Cantwell's frequency-tripler circuit.

Three similar transformers, with rated primary and secondary voltages of 110, were connected as shown in figure 1. Since the fundamental input line-to-neutral voltage was $235/\sqrt{3}$, or 136 volts, the transformers were operated at flux densities somewhat above normal. As shown in Cantwell's paper, this increase of flux density above normal increased the amount of the third-harmonic voltage output.

With no load on the secondary the third-harmonic output voltage was 206. The wave forms of the primary line-to-neutral voltage and the primary line current for this condition are shown in the oscillogram of figure 2. The voltage wave contains a very prominent third harmonic. The current wave contains a noticeable fifth harmonic.

When a resistance load was connected to the output terminals the output voltage dropped rapidly with an increase of output current. The voltage decreased from 206 volts at no load to 103 volts for a load current of 0.78 ampere. The wave forms for this load condition are shown in the oscillogram of figure 3.

In order to make easier the comparison of wave forms for no load and for some load, the oscillogram of figure 4 was taken. This oscillogram shows the wave forms of figures 2 and 3 in the correct phase positions relative to each other, and to the same scales.

Figure 4 shows that as the output current is increased the magnitude of the third-harmonic component of the voltage and the peak value of voltage are reduced. As the output current is increased the primary line current is changed somewhat in wave form, and its peak value is increased.

When a 4.73-microfarad capacitor was connected in series with the resistance load the wave forms became those shown in figure 5. In this case the voltage across the resistance load dropped only to 162 volts at a current of 1.45 amperes.

It is of interest to note that the output current $i_{S3}$ appears to contain a component which is a third harmonic with respect to it. This component thus is a ninth harmonic with respect to the fundamental.

The oscillogram of figure 6 shows the wave forms of figures 2 and 5 in the correct relationship with respect to each other. The wave $i_{L1}$ represents the same current in both figures 2 and 6 but the scale is not the same in each case.

Figure 6 shows that the use of a capacitor in series with the load increases the magni-

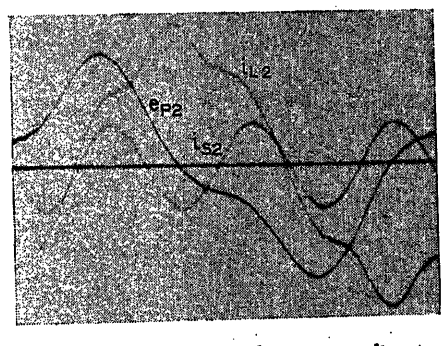

**Fig. 3. Oscillogram of primary line-to-neutral voltage, primary line current, and output current, with a resistance load**

$e_{P2}$—Primary line-to-neutral voltage
$I_{L2}$—Primary line current
$I_{L2}$—2.24 amperes, effective
$I_{S2}$—Output current
$I_{S2}$—0.78 ampere, effective
A unit length is 5.13 amperes and 445 volts

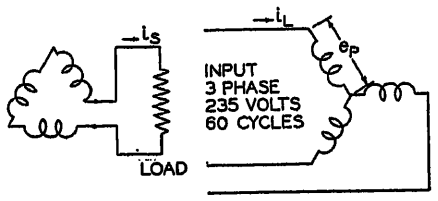

**Fig. 1. Diagram of a frequency-tripling circuit**

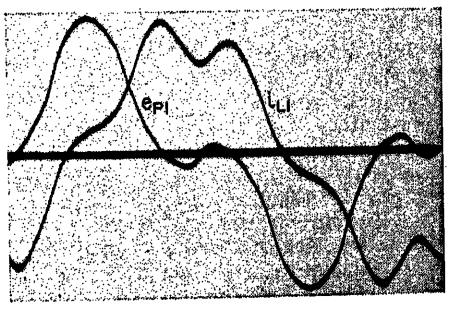

**Fig. 2. Oscillogram of primary line-to-neutral voltage and line current with no load on the secondary of the frequency-tripling circuit**

$e_{P1}$—Primary phase voltage
$I_{L1}$—Primary line current
$I_{L1}$—2.02 amperes, effective
A unit length equals 5.13 amperes and 445 volts (the base of 1/2 cycle is taken as a unit length)

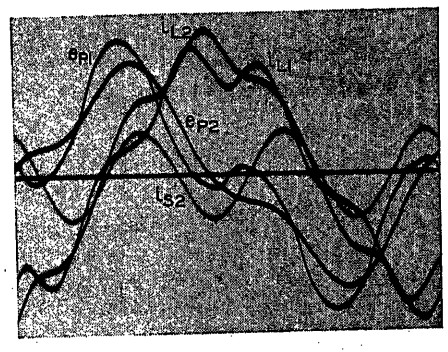

**Fig. 4. Oscillogram of primary line-to-neutral voltages and primary line currents at no load and under load, output current under load conditions**

$e_{P1}$—Primary line-to-neutral voltage at no load
$e_{P2}$—Primary line-to-neutral voltage under load
$I_{L1}$—Primary line current at no load
$I_{L1}$—2.02 amperes, effective
$I_{L2}$—Primary line current under load
$I_{L2}$—2.24 amperes, effective
$I_{S2}$—Output current
$I_{S2}$—0.78 ampere, effective
A unit length is 5.13 amperes and 445 volts

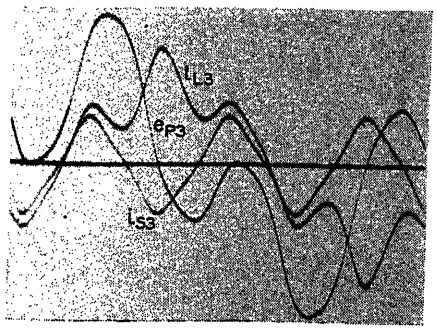

**Fig. 5. Oscillogram of primary line-to-neutral voltage, primary line current, and output current, with a capacitor in series with the resistance load**

$e_{P3}$—Primary line-to-neutral voltage
$i_{L3}$—Primary line current
$I_{L3}$—2.7 amperes, effective
$i_{S3}$—Output current
A unit length equals 9.1 amperes and 445 volts

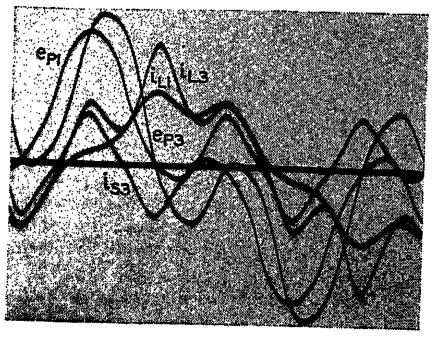

**Fig. 6. Oscillogram of primary line-to-neutral voltages and primary line currents at no load and under load, output current under load conditions**

$e_{P1}$—Primary line-to-neutral voltage at no load
$e_{P3}$—Primary line-to-neutral voltage under load
$i_{L1}$—Primary line current at no load
$I_{L1}$—2.02 amperes, effective
$i_{L3}$—Primary line current under load
$I_{L3}$—2.7 amperes, effective
$I_{S3}$—Output current
$I_{S3}$—1.45 amperes, effective
A unit length is 9.1 amperes and 445 volts

tude of the third-harmonic component of the primary line-to-neutral voltage and also the peak value of the voltage. The primary line current is changed in wave form and its peak value is increased appreciably.

The point made by Cantwell regarding possible overvoltages, when a capacitor is used, is an important one. At one time the writer connected a 10-microfarad capacitor across an open corner of the delta on 3 110-volt transformers. The voltage across the capacitor was found to be more than 1,110 volts.

The transformers used in obtaining the oscillograms shown in this letter were not designed to be used as frequency triplers. The exciting currents are rather large in comparison with the output current, but the general nature of the wave forms in a frequency tripler can be predicted from the oscillograms shown.

Very truly yours,

G. V. MUELLER (A'29, M'35)
Assistant Professor of Electrical Engineering, Purdue University, Lafayette, Ind.

## Qualitative Analysis of Self-Excited A-C Generator

*To the Editor:*

An article in the May 1935 issue of ELECTRICAL ENGINEERING on the subject of self-excited a-c generators of the induction type gave what may be regarded as an introduction outlining the possibilities of using a squirrel-cage induction motor as a generator by connecting suitable capacitance across the terminals and driving the machine mechanically. It may be inferred from this article that the electrical losses plus the load are supplied from the mechanical input; but it is not made clear just how the conversion from mechanical to electrical energy occurs. Also, the question of what determines the output frequency is not satisfactorily answered.

It is not sufficient explanation of the operation of such a machine merely to say that the capacitance draws a leading current (resulting from residual magnetism voltage) which is magnetizing, and therefore the initial voltage increases. This does not take into account the function of the rotor conductors. The operation may be partially explained by saying that a salient-pole rotor less conductors may build up on capacitive load without d-c excitation; and that the bars in a cylindrical squirrel-cage rotor tend to carry the flux around the air gap so that it cuts the stator conductors just as the salient-pole rotor does (except for slip necessary to have this effect).

Such an explanation is helpful but does not explain matters completely.

A concept of all the phenomena involved undoubtedly may be obtained by several different approaches. One approach, which would be of most value quantitatively no doubt, would be to set up equations for all voltages and currents and fluxes, applying Kirchoff's laws for the final solution. However, the following nonmathematical approach probably is as simple as any other concept.

Consider first a squirrel-cage induction motor less squirrel cage; in other words a wound stator with a cylindrical laminated-iron rotor and no rotor conductors. The stator then is merely an iron-core reactance with an air gap. A single-phase winding is taken for simplicity.

Now if a charged capacitor is connected across the terminals, its energy is dissipated through an oscillatory discharge, damped by the stator resistance. If resistance is neglected, the frequency of the current flowing will be given by

$$f_0 = \frac{1}{2\pi\sqrt{LC}}$$

Now suppose rotor bars are introduced and the rotor is driven at a speed

$$RPM = \frac{2 \times 60 f_0}{P}$$

where $P$ is the number of poles.

The rotor revolving at synchronous speed will of course cut the flux produced by the stator resulting from the current flowing of frequency $f_0$ when the charged capacitor is connected. The result will be merely to set up a cross field, and instead of the flux involved in determining the inductance $L$ being a pulsating flux, it is now rotating. This rotating field, however, supports a voltage of the same frequency and magnitude as a pulsating flux of the same maximum amplitude. The voltage in either case is

$$E = K\phi \sin 2\pi f_0 t$$

where $K$ is a constant and $t$ is time.

It is probably beside the point to discuss whether such a condition is stable; that is whether the capacitor discharges just as though the rotor had no conductors. The situation is complicated by the stator and rotor resistance always present in the practical case.

Now suppose the rotor is driven at a speed slightly above synchronous speed as previously defined. This means that if the stator flux continues to rotate at the frequency $f_0$ there is a slip resulting in low-(slip) frequency rotor current. Since the rotor conductors are pushing ahead, the slip current in the bars has a magnetizing effect. The effect of this will be to increase the flux $\phi_0$.

Now this condition may be regarded as increasing the inductance of the stator winding. This in turn reduces the natural period of oscillation, and a new frequency of current through the capacitor exists; that is,

$$(2\pi f_1)^2 = \frac{1}{(L_0 + L_r)\, C}$$

where $L_r$ is the effective increased inductance due to magnetizing effect of rotor current.

This means that the slip of the field as compared with rotor speed increases, which in turn enlarges the slip current and the magnetizing effect of the rotor conductors. A "vicious circle" results, until the machine either loads to saturation or the torque exceeds the capacity of the driver and the speed drops. Since the stator current is flowing at resonant frequency, it is limited only by the circuit resistance.

In many practical cases harmful results will appear, such as building up of voltage sufficient to cause failure of the capacitor, breakdown of generator insulation, or overheating of generator. In a capacitor type of motor with certain types of connections, circulating currents may be caused by this generating action, which produces a large negative torque preventing the motor from pulling up to speed.

It would seem desirable to have means available to control frequency of generator output, and output voltage. Perhaps the easiest method of controlling frequency is the use of a salient-pole rotor. This would also tend to control voltage build-up, since the "vicious circle" outlined previously would not exist.

Next, in order to have dependable build-up, a small d-c excitation or a permanent magnet might be introduced.

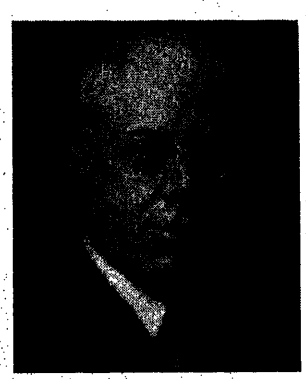
The net result is an a-c generator or magneto with a capacitor across the terminals or perhaps in series with the load to hold up or boost the delivered voltage. Such an arrangement is, of course, by no means new.

Very truly yours,

CHARLES T. BUTTON (A'26)
Sales Engineer, The Holtzer-Cabot Electric Co., Boston, Mass.

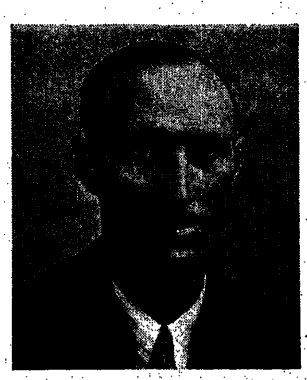
# Personal Items

F. L. HUNT (A'05, F'17) director of economics and engineering of Western Massachusetts Companies, Greenfield, Mass., has been elected vice-president of that association and of each of its constituent utility companies, and assigned the duty of general charge of operations of those companies. Mr. Hunt was born at Delta, Iowa, in 1879, and was graduated from the University of Nebraska with the degree of bachelor of science in electrical engineering in 1902. Following his graduation he spent 3 years in the testing department of the General Electric Company, Schenectady, N. Y. In 1905 he was transferred to the Boston, Mass., offices of the General Electric Company, where he was in charge of construction work in New England, and later assistant district engineer. In 1913 Mr. Hunt accepted the position of chief engineer of the Turner Falls Power and Electric Company and allied companies in Greenfield, Mass., and in 1927 when Western Massachusetts Companies was formed, including the Turner Falls Power and Electric Company, United Electric Light Company, Pittsfield Electric Company, and the Greenfield Electric Light and Power Company (now Western Massachusetts Electric Company), Mr. Hunt was appointed director of economics and engineering of those companies. He has served the Institute as a member of the committees on protective devices, 1914–16 and 1919–29; standards, 1923–32; and meetings and papers (now technical program), 1926–28. Mr. Hunt is the author of several Institute papers.



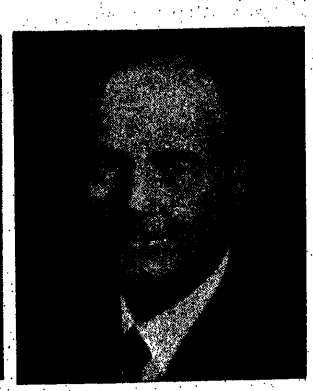
A. C. SCHWAGER (A'24, M'31) formerly chief engineer of the Pacific Electric Mfg. Corporation, San Francisco, Calif., has been elected vice-president in charge of engineering. Mr. Schwager, born in Switzerland in 1899, completed his general and technical education and began his professional career in that country as a technical assistant in the test laboratory of the Electric Manufacturing Company, at Oerlikon. Later, during 1922–23, he served as assistant professor at the Institute of Technology in Zurich. He came to the United States in 1923, whereupon he joined the staff of the Electrical Testing Laboratories, New York, N. Y., as a technical assistant on high-voltage cable research, but in the following year transferred his affiliation to the New York Edison Company, where he served as a draftsman on power-plant and substation design. During 1925–26 he continued the same type of work with the Pacific Gas and Electric Company, San Francisco, Calif. Since 1926 Mr. Schwager has been associated continuously with the Pacific Electric Mfg. Corporation, first as test engineer in charge of the test laboratory and successively as executive engineer in charge of the engineering department, as design engineer in charge of oil circuit breaker design, and as chief electrical engineer. In 1931 he was appointed chief engineer of the company. Mr. Schwager has contributed liberally to technical literature by means of articles in trade periodicals and through several papers presented before the Institute.

WALTER CARR (A'14, M'17) who was elected a vice-president of the Connecticut Railway and Lighting Company, Bridgeport, in 1936, recently was elected a director of the company, and now is in charge of the company's operations. Mr. Carr was born October 27, 1888, at Fredericton, N. B., Canada, and was graduated from Stevens Institute of Technology with the degree of mechanical engineer in 1910. Upon graduation he entered the employ of the General Electric Company, Lynn, Mass., as a test engineer, and remained there for one year before returning to Fredericton to become superintendent of the municipal lighting plant of that city. In 1912 Mr. Carr accepted a position with the United Gas Improvement Company, Philadelphia, Pa., and remained for more than 24 years, during which period his work consisted of the design, construction, and operation of street railway and motor-coach facilities.



F. W. MACNEILL (A'11, M'22) district sales engineer for the Canadian General Electric Company, Vancouver, B. C., recently was elected to the council of The Engineering Profession in British Columbia to represent the electrical engineers of the province. Mr. MacNeill was born at Ormond, Ont., Canada, in 1882, and received a diploma in mechanical and electrical engineering from the faculty of applied science of the University of Toronto in 1907. During the following year he pursued postgraduate work at the same institution and received the degree of bachelor of applied science. Upon graduation in 1908, Mr. MacNeill entered the employ of the Canadian General Electric Company, and for 2 years was engaged in electrical testing and design at the Peterboro, Ont., works of that company. In 1910 he was made sales engineer in the Toronto offices of that company, but in the same year was appointed district sales manager for Alberta and eastern British Columbia. He has held his present position as district sales engineer for the Province of British Columbia since 1917. Mr. MacNeill was chairman of the Institute's Vancouver Section during 1923–24.

E. H. COLPITTS (A'11, F'12) vice-president of the Bell Telephone Laboratories, Inc., New York, N. Y., has retired from active service. Doctor Colpitts was born January 19, 1872, at Point du Bute, N. B., Canada, and received the degree of bachelor of arts at Mt. Allison College (1893) and Harvard University (1896); in 1897 he received the degree of master of arts at Harvard. He continued his work in the Harvard graduate school for $1\frac{1}{2}$ years, but received no further degree; however, in 1926 Mt. Allison College conferred upon him the honorary degree of doctor of laws. After terminating his graduate work in mathematics and physics he entered the employ of the American Bell Telephone Company, being engaged in research problems in telephone transmission. A few years later, when this department was merged with the engineering department of the American Telephone and Telegraph Company, Doctor Colpitts continued with the new company until 1907, when he was transferred to the engineering department of the Western Electric Company, New York. In 1917 he became assistant chief engineer of that company, and in 1924 was elected assistant vice-president of the American Telephone and Telegraph Company. He became vice-president of the Bell Telephone Laboratories in 1933. Doctor Colpitts has been granted many patents, and is the author of numerous technical papers. He served the Institute as a member of the committee on standards, 1916–17; telegraphy and telephony (now communication), 1919–24; and research, 1922–37. He is a member of the Institute of Radio Engineers, the American Physical Society, and several other technical organizations.



B. W. DUNKELBURGER, JR. (A'36) formerly technician and supervisor in the visual instruction department of North Dakota State College, Fargo, now is principal of The Northwood (N. D.) High School. Mr. Dunkelburger received the degree of bachelor of science in education

F. L. HUNT

A. C. SCHWAGER

WALTER CARR

at North Dakota State College in 1936, and during his undergraduate training acted as assistant principal and dean of the Boys Agricultural and Mechanics Arts High School, conducted by North Dakota State College.

W. L. WHYTE (A'35) until recently stationed at Ceará, Brazil, with the Ceará Tramway, Light, and Power Company, Ltd., recently accepted an appointment as technical adviser in electrical matters to the Uganda Government. Mr. Whyte has had broad experience in electrical construction and operation in Argentina, Brazil, Great Britain, and the Federated Malay States. He is a member of the Institution of Electrical Engineers (Great Britain).

B. E. ANDERSON (M'35) formerly assistant electrical engineer in the Public Works Department, United States Navy Yard, Mare Island, Calif., now is employed by the Phoenix Engineering Corporation, New York, N. Y. Mr. Anderson, a native (1896) of Colorado Springs, Colo., has had wide experience in public utility work in the United States and abroad.

JACK DELMONTE (A'36) has resigned his position as junior electrical engineer at the naval aircraft factory, United States Navy Yard, Philadelphia, Pa., to accept a position as laboratory technician in the engineering research laboratories of the Firestone Tire and Rubber Company, Akron, Ohio.

W. A. STELZER (A'34) who has been an electric dredge engineman, United States Engineers, Fort Peck, Mont., now is employed as a draftsman in the electrical engineering department of the Commonwealth and Southern Corporation, Jackson, Mich.

F. M. FARMER (A'02, F'13, director) vice-president and chief engineer, Electrical Testing Laboratories, New York, N. Y., has been appointed a member of the Institute's executive committee to fill the unexpired term of the late Junior Past-President E. B. Meyer.

J. S. BROWN (A'23, M'31) who has been employed in the survey department of the Potomac Electric Power Company, Washington, D. C., now is employed in the electrical engineering department of the Duquesne Light Company, Pittsburgh, Pa.

H. W. RICHTER (A'36) formerly a designer for the Dormeyer Manufacturing Company, Chicago, Ill., now is employed as an electrical engineer for the Allen Electric and Equipment Company, Kalamazoo, Mich.

L. A. HELGESSON (A'34) formerly assistant engineer in the steam heat department of the Northwestern Electric Company, Portland, Ore., has resigned to accept a position in the engineering department of L. R. Teeple Company, Portland.

R. L. SMITH (M'34) formerly an electrical engineer for the Buffalo, Niagara, and Eastern Power Corporation, Buffalo, N. Y., now is employed by the Stone and Webster Engineering Company, Boston, Mass.

L. B. ECKLES (A'36) formerly an electrical designer for the Consumers Power Company, Jackson, Mich., recently accepted a position as associate engineer with the Iowa Agricultural Business Corporation Service, Des Moines.

J. K. MOORE (A'36) who has been an electrical engineer for the Hydroelectric Commission of the State of Oregon, Salem, now is employed by the Eastern Oregon Light and Power Company, Baker.

E. J. RAMALEY (A'32) formerly senior rodman, United States Bureau of Public Roads, Denver, Colo., now is engaged in research work at Battelle Institute, Columbus, Ohio.

I. E. MOUROMTSEFF (A'25) research engineer, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has been transferred to the lamp division of that company at Bloomfield, N. J.

ROBERT MACDONALD (A'28) formerly power engineer for Ericcson Telephones, Ltd., Beeston, Nottingham, England, now is employed by the Western Electric Company, Kearny, N. J.

E. D. LILJA (A'31) formerly an electrical engineer with Barber-Colman Company, Rockford, Ill., now holds a similar position with the Woodward Governor Company, Rockford.

F. R. MARION (A'26) has been transferred from the operating engineering department of Electrical Research Products, Inc., New York, N. Y., to the Western Electric Company, Kearny, N. J.

# Obituary

WILLIAM STANTON TWINING (A'05, M' 13) retired engineer, Ambler, Pa., died February 8, 1937. Mr. Twining was born February 20, 1865, near Titusville, Pa., attended Cornell University, and was graduated from Allegheny College in 1887, as a civil engineer. During the 3 following years he remained at Allegheny College as an instructor in chemistry and engineering, and in 1890 entered the railway engineering department of the Thomson-Houston Company at Boston, Mass., where his work consisted of power-station design and construction. In 1901 he was engaged as assistant engineer for the Union Railway Company and the Interborough Rapid Transit Company, New York, N. Y., and remained in that position until 1903, when he transferred his affiliation to the Peoples Traction Company, Philadelphia, Pa. In 1905 Mr. Twining was appointed chief engineer of that company and its successor, the Union Traction and Philadelphia Rapid Transit Company, in which position he was in general charge of all engineering work. From 1910 to 1914 he served as engineering manager for the consulting engineering firm of Ford, Bacon, and Davis, New York, N. Y. He then returned to Philadelphia to become the first director of transit of that city. Mr. Twining retired from active service in 1925.

EUGENE L. ALEXANDER (A'35) formerly an electrical draftsman for the New York (N. Y.) Rapid Transit Corporation, died November 1, 1936, according to word just received at Institute headquarters. Mr. Alexander was born October 1, 1882, at Tiflis, Russia, and received the degree of electrical engineer from the University of Liege (Belgium) and the Electrical Institute of Emperor Alexander III (Russia) in 1908 and 1910, respectively. Following his graduation he was appointed assistant superintendent of the electrical department of the Steel, Locomotive, and Shipbuilding Works, Soromovo, Russia, and remained in that capacity until 1914, when he was made superintendent of the electrical power plant and assistant superintendent of the electrical department in the Metallurgical Corporation of Nicopol Marioupol. During the year 1918–19 Mr. Alexander was superintendent of the municipal electric plant of the City of Marioupol, Russia, and in the following year he accepted a position as assistant superintendent of a central station of the Compagnie Ottomane d' Electricitè, Constantinople, Turkey. In 1925 he came to the United States and entered the employ of The New York (N. Y.) Edison Company as an electrical draftsman. In 1928 he transferred to the New York Rapid Transit Company in a similar position.

WALTER EDWARD BARE (A'29) general commercial manager of the Southern Bell Telephone and Telegraph Company, Atlanta, Ga., died February 5, 1937. Mr. Bare was born September 22, 1882, at Lexington, Va., and was educated in private schools in Florence, Ala. He entered the employ of the Southern Bell Telephone and Telegraph Company as a lineman in 1903 and served that company continuously, except for a brief service in the United States Army during the World War. From 1905 to 1916 he acted as manager of various local plants of the company, and in 1919 was promoted to district manager in the Montgomery, Ala., offices. During 1921–23 he held a similar position in the Birmingham offices before being appointed Alabama state manager for the company. Mr. Bare became commercial manager in 1930.

FREDERICK A. SCHEFFLER (A'93, M'96, F'12, member for life) retired electrical engineer, formerly connected with The Babcock & Wilcox Co., New York, N. Y., died

February 23, 1937. Mr. Scheffler was born December 20, 1858, at Galion, Ohio, and was graduated from the Paterson (N. J.) Seminary in 1871, following which he was associated briefly with several companies, including the Rhode Island Locomotive Works, Brown and Sharpe, and the Harris Corliss Engine Company, before joining the Edison Electric Light Company, New York, N. Y., in 1881. He was placed in charge of the engineering department of the Edison company, and in that capacity designed an electric locomotive used in experimental work by Thomas A. Edison (A'84, M'84, HM'28, John Fritz Medalist '08). In 1885 Mr. Scheffler became superintendent of the Erie City Iron Works, Erie, Pa., which position he held for 5 years before resigning to become acting general superintendent of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., in 1889. Later he served as general superintendent of the Brush Electric Company (1891–93), the Sprague Electric Company (1899–1900), and the Marine Engineering and Machinery Company (1902–04). Mr. Scheffler was affiliated with The Babcock & Wilcox Co. and its subsidiary companies for many years. He served the Institute as a member of the committee on power stations from 1916 to 1919 and from 1922 to 1935, and as a member of the special committee on the Edison Memorial during 1932 and the Edison Medal committee, 1913–18, 1922-27, and 1930–33. He was a member of The American Society of Mechanical Engineers.

# Membership

## Recommended for Transfer

The board of examiners, at its meeting on March 17, 1937, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

**To Grade of Fellow**

**Baldwin, R. L.**, consulting engineer, Burns and McDonnell Engineering Company, Kansas City, Mo.

**Conrad, Frank**, assistant chief engineer, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

2 to Grade of Fellow

**To Grade of Member**

**Anderson, C.**, headquarters sales and application, instruments and measuring devices, Westinghouse Electric and Manufacturing Company, Newark, N. J.

**Balch, E. C.**, chief engineer, Michigan Bell Telephone Company, Detroit, Mich.

**Balet, J. W.**, engineer, Consolidated Edison Company of New York, Inc., New York, N. Y.

**Boehne, E. W.**, design engineer, General Electric Company, Philadelphia, Pa.

**Bronaugh, J.**, sales representative, Allis-Chalmers Manufacturing Company, Richmond, Va.

**Carroll, J. S.**, associate professor, electrical engineering department, Stanford University, Calif.

**Gardner, J. E.**, electrical engineer, Chicago, Burlington and Quincy Railroad Company, Chicago, Ill.

**Joboolian, E.**, squad boss, Gibbs and Hill, New York, N. Y.

**Johnson, G. E.**, chief engineer and general manager, The Central Nebraska Public Power and Irrigation District, Hastings, Neb.

**King, R. T.**, industrial power representative, Public Service Electric and Gas Company, Trenton, N. J.

**Logan, K. H.**, senior electrical engineer, National Bureau of Standards, Washington, D. C.

**McCormack, J. E.**, distribution engineer, New York and Queens, Electric Light and Power Company, Flushing, N. Y.

**Michaels, A. P.**, consulting engineer, A. P. Michaels Engineering Firm, Orlando, Fla.

**Walker, E. W.**, proprietor, E. W. Walker, Birmingham, England.

**Zangler, R. M.**, standardization of mfg. practices and engineering data, Anaconda Wire and Cable Company, Hastings-on-Hudson, N. Y.

15 to Grade of Member

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the national secretary before April 30, 1937 or June 30, 1937, if the applicant resides outside of the United States or Canada.

Abramowitz, A., 579 East 140th Street, New York, N. Y.

Adams, J. T. (Member), Public Service Company of Oklahoma, McAlester, Okla.

Alenius, E., Bell Telephone Laboratories, Inc., New York, N. Y.

Allen, T. O., Humble Oil and Refining Company, Anahuac, Texas.

Anders, R. D., Philadelphia Electric Company, Phoenixville, Pa.

Anderson, C. B., 318 Public Service Building, Tulsa, Okla.

Angier, J. F., National Bureau of Standards, Washington, D. C.

Anthony, B. M., Tennessee Valley Authority, Wilson Dam, Ala.

Arnn, E. L., General Electric Company, Philadelphia, Pa.

Aruck, M., Bell Telephone Laboratories, Inc., New York, N. Y.

Babcock, K. L., Underwood Elliott Fisher Company, Hartford, Conn.

Babin, B. P., Westinghouse Electric & Manufacturing Company, New Orleans, La.

Bader, R. D., Philadelphia Storage Battery Company, Philadelphia, Pa.

Bailey, A. (Member), American Telephone and Telegraph Company, New York, N. Y.

Balfour, M. W., Public Service Company of Northern Illinois, Chicago, Ill.

Banks, J. F., Commonwealth Edison Company, Chicago, Ill.

Barnes, C., Jr., 1153 N. Dearborn Street, Chicago, Ill.

Barrett, W. G., 10 West 90th Street, New York, N. Y.

Basore, N. D., Public Service Company of Oklahoma, Hartshorne, Okla.

Baum, D. C., 5001 Goodridge Avenue, Riverdale-on-Hudson, N. Y.

Bazak, H. V., Consolidated Edison Company of New York, Inc., New York, N. Y.

Beatty, F., University of Kentucky, Lexington, Ky.

Beck, J. M., Jr., Westinghouse Electric and Manufacturing Company, Wichita, Kans.

Behm, T. R., Syracuse Lighting Company, Syracuse, N. Y.

Behrens, H. J., Consolidated Edison Company of New York, Inc., New York, N. Y.

Bejarano, J. R., 87 Grove Street, Lynbrook, N. Y.

Bell, R. O., 1501 South 77th Street, Milwaukee, Wis.

Benson, B. T., Foreign and Domestic Commerce, Washington, D. C.

Bernard, W. B., 1407 West University Avenue, Gainesville, Fla.

Bingham, W. H. (Member), Westinghouse Electric Supply Company, New York, N. Y.

Birmingham, Paul V., 1285 Oak Grove Avenue, Burlingame, Calif.

Bischof, L. J., General Electric Company, New York, N. Y.

Bishop, R. H. (Member), Public Servic Company of Oklahoma, Tulsa, Okla.

Blom, L. A., 2306 N. Knox, Chicago, Ill.

Boehr, J. W., Westinghouse Electric and Manufacturing Company, Sharon, Pa.

Borton, J. R., Puget Sound Power and Light Company, Seattle, Wash.

Bossard, G. E., General Kontrolar Company, Inc., Dayton, Ohio.

Bottum, E. L., Carnegie Illinois Steel Corporation, Gary, Ind.

Boyd, A. G., General Electric Company, Schenectady, N. Y.

Bradstock, M. C., General Electric Company, Cleveland, Ohio.

Brazeel, J. P., Public Service Company of Oklahoma, Okemah, Okla.

Brewer, L. G., Montana Power Company, Havre, Mont.

Brewer, R. D., Ford Motor Company, Dearborn, Mich.

Bridegam, W. J., E. M. Gilbert Engineering Corporation, Reading, Pa.

Brignac, E. M., Industrial Electric Company, New Orleans, La.

Brody, E. W., Line Material Company, South Milwaukee, Wis.

Brown, J. G., General Electric Company, Schenectady, N. Y.

Brown, J. T., Jr., Carolina Power and Light Co., Raleigh, N. C.

Burleigh, C. LeM., Jr., Harvard Business School, Boston, Mass.

Campbell, R. P., Tennessee Valley Authority, Wilson Dam, Fla.

Carioni, H. M., Canadian Westinghouse Company, Ltd., Hamilton, Ont.

Carlberg, H. A., Wisconsin Public Service Corporation, Green Bay, Wis.

Carroll, D. R., Bell Telephone of Pennsylvania, Pittsburgh, Pa.

Chambers, M. A., Standard Oil Company, Shreveport, La.

Cherry, J. S., Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

Clough, F. P., Y. M. C. A., 8 East 3rd Street, New York, N. Y.

Cobert, C. S., Clark Controller Company, Cleveland, Ohio.

Coho, O. C., Jr., General Electric Company, Schenectady, N. Y.

Coleman, I. M., 581 Academy Street, New York, N. Y.

Colquhoun, W. H., in care of Maurice R. Scharff, New York, N. Y.

Connolly, D. E., 1738 Webster Avenue, New York, N. Y.

Contardi, A., Jr., 959 Middlesex Avenue, Metuchen, N. J.

Cooper, D. T., Brown Instrument Company, Philadelphia, Pa.

Crooks, W. E., 41 Duggan Avenue, Toronto, Ont., Canada.

Crosby, T. H., Canadian Westinghouse Company, Ltd., Vancouver, B. C., Canada.

Dalrymple, H. C., 46 Colony Drive East, West Orange, N. J.

Darrah, M. D., 4417 Swiss Avenue, Dallas, Texas.

Deardorff, R. W., Pacific Telephone and Telegraph Company, Portland, Ore.

DeBlois, W., Lincoln Electric Company, Boston, Mass.

deCarrera, R., General Electric Company, Schenectady, N. Y.

Degentesh, H. E., Square D Company, New York, N. Y.

Dermond, F., Bell Telephone Laboratories, Inc., New York, N. Y.

Dickinson, H. C., General Electric Company, Lynn, Mass.

Dingman, J. E. (Member), American Telephone and Telegraph Co., New York, N. Y.

Doede, H. C., Swift and Company, Chicago, Ill.

Doherty, J. F., Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

Dollins, C. B., Jr., Tennessee Valley Authority, Wilson Dam, Ala.

Dubsky, F. H., Commonwealth Edison Company, Chicago, Ill.

Dudley, R. B., The Jeffrey Manufacturing Company, Columbus, Ohio.

Kralosky, F. B., 2622 Bartold Street, N. S., Pittsburgh, Pa.
Kulikowski, E. F., Jensen Radio Manufacturing Co., Chicago, Ill.
Kyes, J. M., 1946 Washington Street, San Francisco, Calif.
Lane, R. K. (Member), Public Service Company of Oklahoma, Tulsa, Okla.
Lantz, L. E., Jr., Jacksonburg, W. Va.
Lawson, S. A., Gustav Hirsch Organization, Columbus, Ohio.
Lee, H. B., Rural Electrification Administration Washington, D. C.
Lefthes, N., 11 Ward Street, Salem, Mass.
Legg, V. E. (Member), Bell Telephone Laboratories, Inc., New York, N. Y.
Lenhardt, W. C., Bethlehem Steel Company, Cornwall, Pa.
Levine, M. E., Tung-Sol Lamp Works, Newark, N. J.
Lobosco, R. R., Linde Air Products Company, Newark, N. J.
Lovoff, A., 3496 Anderdon Street, Detroit, Mich.
Ludden, J. H., 80 Mill Street, Athens, Ohio.
Lundgren, L. O., Kennecott Wire and Cable Company, Phillipsdale, R. I.
MacAllister, C. C., General Electric Company, Lynn, Mass.
MacKay, E. L., General Electric Company, Schenectady, N. Y.
Mansfield, T. E. (Member), Oklahoma Power and Water Company, Sand Springs, Okla.
Marshall, M. B., Jr., General Electric Company, Erie, Pa.
Martin, W. L., Triad Manufacturing Company, Pawtucket, R. I.
Martini, J. A., American Telephone and Telegraph Company, New York, N. Y.
Matheo, M., Consolidated Edison Company, New York, N. Y.
Matzinger, J. R., American Electric Switch Corporation, Minerva, Ohio.
May, M. H., Interstate Power Company, Albert Lea, Minn.
Mayer, J. A., Graybar Electric Company, Cleveland, Ohio.
Mayers, J. H., 917 Druid Hill Avenue, Baltimore, Md.
McArthur, D., General Electric Company, West Lynn, Mass.
McCormack, C. M., Phelps-Dodge Copper Products Corporation, Yonkers, N. Y.
McCrary, J. H. (Member), Public Service Company of Oklahoma, Tulsa, Okla.
McDowell, E. P., General Electric Company, Schenectady, N. Y.
McLeod, G. R., General Electric Company, West Lynn, Mass.
Mearns, W. J., Continental-Diamond Fibre Company, Bridgeport, Pa.
Messler, W. H., Winchester Repeating Arms, New Haven, Conn.
Michaelis, J. L., Pittsburgh Plate Glass Company, Barberton, Ohio.
Miller, R. E., Allis-Chalmers Manufacturing Company, Milwaukee, Wis.
Mooney, V. J., General Electric Company, Schenectady, N. Y.
Morgan, L. W., Commonwealth Edison Company, Chicago, Ill.
Morris, R. V., Gary Heat, Light and Water Company, Gary, Ind.
Morrison, H. A., Central Nebraska Public Power and Irrigation District, Hastings, Neb.
Moss, A. G. (Member), Public Service Company of Oklahoma, McAlester, Okla.
Mostrom, J., Phillips Petroleum Company, Bartlesville, Okla.
Motz, C. A., General Electric Company, Schenectady, N. Y.
Murphy, J. T., Shell Petroleum Corporation, Plaquemine, La.
Nauert, A. G., American Telephone and Telegraph Company, New York, N. Y.
Nelson, C. T., Public Service Company of Oklahoma, Okmulgee, Okla.
Nickerson, G., Texas Development Corporation, Lafitte, La.
Nimmer, F. W., Ohio Edison Company, Akron, Ohio.
Norton, T. P., 3 Bradford Street, Salem, Mass.

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute record. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Godoy, Ernesto R., Cia. Tel. y Tel. Mex., 16 de Septiembri No. 13, Mexico, D. F., Mex.
Hale, Edward E., Public Service Commission of New York, 80 Centre St., New York, N. Y.
Little, Leroy C., 3414—17th St., N., Cherrydale, Va.
Moore, Everett, 821 Sunset Blvd., Los Angeles, Calif.
Nash, G. H., 2-A Holland Road, London W.14, England.
Peach, Paul S., Upperville, Va.
Pollastro, John B., Helper, Utah.
Sawyer, Fred E., 811 E. Wisconsin Ave., Milwaukee, Wis.
Wickel, F. A., Pier 42, Dollar S. S. Lines, San Francisco, Calif.

9 Addresses Wanted

# Engineering Literature

## New Books in the Societies Library

Among the new books received at the Engineering Societies Library, New York, recently, are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface of the book in question.

ELECTRON TUBES in INDUSTRY. By K. Henney. 2nd edition. New York and London, McGraw-Hill Book Company, 1937. 538 pages, illustrated, 9x6 in., cloth, $5.00. Discusses the practical uses of thermionic and light-sensitive tubes outside the communication field.

ELEMENTS of ELECTRICITY. By W. Esty, R. A. Millikan, and W. L. McDougal. Chicago, American Technical Society, 1937. Illustrated, 9x6 in., cloth, $2.00. A textbook for beginners.

INTRODUCTORY STUDY of ELECTRICAL CHARACTERISTICS of POWER and TELEPHONE TRANSMISSION LINES. By F. W. Norris and L. A. Bingham. Scranton, Pa., International Textbook Company, 1936. 272 pages, illustrated, 9x5 in., leather, $2.50. Adaptable to an introductory course in the principles of electrical transmission. Aims to develop the student's ideas of the electric and magnetic fields and his ability to deal with circuits involving distributed constants.

JONES RADIO HANDBOOK. By F. C. Jones. 1937 edition. San Francisco, Pacific Radio Publishing Company, 1936. 456 pages, illustrated, 9x6 in., paper, $1.50. Presents the theory of radio communication and gives practical instruction upon the construction of transmitters and receivers, and radio-therapeutic apparatus; intended for the radio amateur.

(KEMPE'S) ENGINEER'S YEAR-BOOK of Formulae, Rules, Tables, Data, and Memoranda for 1937, 43rd Annual Issue, revised by L. St. L. Pendred. London, Morgan Brothers, 1937. 2,676 pages, illustrated, 7x5 in., leather, 31s. 6d. Deals with every phase of engineering and affords a survey of modern practice.

OUTLINE of the HISTORY of MATHEMATICS. By R. C. Archibald. 3rd edition. Oberlin, Ohio, Mathematical Association of America, Inc. 62 pages, 9x6 in., paper, $0.50. A sketch of the development of mathematics based upon 2 lectures delivered in 1931 at a summer school for engineering teachers organized by the Society for the Promotion of Engineering Education.

PROCEDURE HANDBOOK of ARC WELDING, DESIGN, and PRACTICE. 4th edition. Cleveland, Ohio, Lincoln Electric Company, 1936. 819 pages, illustrated, 9x6 in., leather, $1.50. Discusses in a practical manner the equipment and technique of arc welding, the design of arc-welded machinery and structures and the applications of arc welding in manufacturing, construction, and repairs.

The RENAISSANCE of PHYSICS. By K. K. Darrow. New York, Macmillan Company, 1936. 306 pages, illustrated, 9x6 in., cloth, $3.00. Intended primarily for the layman. Discusses the constitution of matter, transmutation, and other basic questions. Based upon a course of lectures at Lowell Institute.

STATISTICAL YEAR-BOOK of the WORLD POWER CONFERENCE. No. 1. 1933 and 1934. Edited, with an Introduction and Explanatory Text by F. Brown. London, World Power Conference, Central Office; American Committee, Interior Building, Washington, D. C., 1936. 111 pages, tables, 11x9 in., paper, $5.00. Contains statistics of the resources, stocks, imports, exports, and consumption of power and power sources during 1933 and 1934 for all countries for which it was possible to obtain information.

STEAM-ELECTRIC POWER STATIONS. By C. F. John. Scranton, Pa., International Textbook Company, 1936. Illustrated, 8x5 in., leather, $1.50. An elementary descriptive text on power-plant equipment and operation, designed for operating men.

STORM LOADING and STRENGTH of WOOD POLE LINES and a STUDY of WIND GUSTS. By R. H. Sherlock, M. B. Stout, W. G. Dow, J. S. Gault, and R. S. Swinton. University of Michigan, Ann Arbor; sponsored by Edison Electric Institute, New York, 1936. 183 pages, illustrated, 9x6 in., cloth, $2.00 to members; $5.00 to others. Contains information about the wind forces acting against the poles and conductors of a power line during storms, of determining the strength of wood poles under these conditions and of studying the structure of winds during storms.

Die TRANSFORMATOREN. (Die Wechselstromtechnik, edited by I. L. la Cour. Bd. 2.) By I. L. la Cour and K. Faye-Hansen. 3rd edition. Berlin, Julius Springer, 1936. 699 pages, illustrated, 9x6 in., cloth, 48 rm. Discusses the theory, construction, calculation, and operation of transformers.

**Engineering Societies Library**
29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a co-operative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Industrial Notes

**General Electric Sales Up.**—At the March meeting of the Board of Directors of the General Electric Co. President Gerard Swope announced that orders received for the first two months of 1937 amounted to $64,000,000, an increase of 79 per cent over the corresponding period of last year, and that sales billed in the first two months were $45,000,000, an increase of 39 per cent over the same period last year. Sales billed for 1936 amounted to $268,545,000, compared with $208,733,000 for 1935, an increase of 29 per cent.

**Construction Work Gains.**—According to F. W. Dodge Corp., the total construction work started in the first two months of 1937 in the 37 eastern states amounted to $431,434,800, a gain of 22 per cent over the corresponding two-months total of $355,211,900 for 1936. Residential building amounted to $141,435,400 or a gain of more than 100 per cent over the total of $68,615,000 for the first two months of 1936. Public works and utilities started during the first two months of 1937 totaled $128,079,200 as against $133,506,200 for the same two months of last year. The decline from last year in this division of the construction industry is entirely due to the slowing-up of the PWA program.

**Aerovox Condensers Now Made in Canada.**—The control of the former Polymet Delta Co. of Hamilton, Ont., has been taken over by Aerovox Corporation. Henceforth the Canadian plant will operate as Aerovox Canada Limited, producing a line of Aerovox dry and wet electrolytic condensers, also mica and paper condensers, for the Canadian trade. The output will conform with the engineering and production standards of the Brooklyn plant according to S. I. Cole, president of the parent company.

**Westinghouse Reports Increased Business.**—The annual report for 1936 of the Westinghouse Electric & Mfg. Co. shows orders received amounting to $182,521,304, an increase of 48 per cent over the previous year. Sales billed totaled $154,469,031, an increase of 26 per cent over 1935. Unfilled orders at the end of the year amounted to $48,490,919 compared with $27,137,075 at the end of the previous year.

**New Battery Tester.**—An instrument for quickly checking the working condition of glass jar type cells used in railway signal service has been developed by the Electric Storage Battery Co., Philadelphia, Pa., termed the Exide "Minute Man." The test is made by discharging the cell at approximately its one minute rated capacity. In this manner the same practical results are obtained as from a 1- or 8-hour-rate discharge test.

**New Molding Materials.**—Many molded plastic parts, due to the conditions under which they are used, require better resistance to shock or impact than is afforded by general purpose molding materials. In order to meet the varied requirements for impact strength, Bakelite Corp., New York, has developed a new line of Bakelite molding materials which range in impact strength on an A.S.T.M. standard test specimen from 0.22 to 2.0 ft. lbs. energy to break (2.75 to 25 ft. lbs. per inch square). These new molding materials are particularly suitable for handset telephones, instrument cases, junction boxes, and other parts requiring relatively high impact or shock resistance.

# Trade Literature

**Relays.**—Bulletin GEA-2524, 8 pp. Describes undervoltage and phase-rotation relays, type ICR, instantaneous-time delay, for the protection of motors and synchronous converters. General Electric Co., Schenectady, N. Y.

**Service Equipment.**—Catalog, 96 pp. Describes a wide range of general purpose and safety switches, panels and cabinets, switch-centers, breakers, industrial cable ducts and fittings, etc. Bull Dog Electric Products Co., Detroit, Mich.

**Voltage Regulators.**—Bulletin 1170B, 36 pp. Describes type AFR automatic feeder voltage regulators. The purpose, construction, and advantages of such equipment, illustrated throughout, are treated at length. Allis-Chalmers Mfg. Co., Milwaukee, Wis.

**Watthour Meters.**—Cat. Sec. 42-215, 16 pp. Describes polyphase watthour meters for house service. Application, construction, performance characteristics, wiring diagrams and ratings for the various available types are included. Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

**Motor Generator Sets.**—Bulletin 501, 4 pp. Describes and illustrates various types of motor generator sets, built in sizes up to 500 kw and supplied in a variety of combinations. Reliance Electric & Engg. Co., 1086 Ivanhoe Road, Cleveland, O.

**Distribution Capacitors.**—Bulletin GEA-2494, 20 pp. Describes Pyranol-filled, pole-type distribution capacitors. According to the bulletin, 99.82 per cent of the Pyranol capacitors manufactured in the last 6 years have a perfect operating record. General Electric Co., Schenectady, N. Y.

**Building Wires and Cables.**—Bulletin BW3, 48 pp. Describes electrical conductors for industrial power and lighting circuits for building of all types; includes tables on wire gauges, formulae for calculating electrical properties of circuits, conversion tables, electrical symbols for architectural plans, etc. General Cable Corp., 420 Lexington Ave., New York.

**Noise Meter.**—Bulletin, 4 pp. Describes the new type 759-A sound-level meter for measuring noise. Features of the new meter include standardized readings, unusual sensitivity, non-directional pick-up, self-contained and portable, weighing only 23½ lbs. The new device is very easy to operate and is comparatively low priced. Bulletin 20, a comprehensive manual on noise measurements, is also available. General Radio Co., Cambridge, Mass.

**Wiring Survey.**—32 pp., "Industrial Guide for Selection of Wire & Cable." A comprehensive, practical treatise on electrical conductors used for industrial purposes and methods of modernizing circuits. Chapters included cover the factors affecting the selection of wire and cables; guide to determining types of insulation; how to use charts; power circuits; standard building wire and cable; flexible cords and cables; control circuits. Anaconda Wire & Cable Co., 25 Broadway, New York City.

**Circuit Breakers.**—Cat. 6-Sec. 9, 2 pp. Describes a new class TCR-1 indoor, oil-tight circuit breaker with a rating of 75,000 kva interrupting capacity, available in ratings up to 2,000 amperes, 5,000 volts, and for both automatic and non-automatic operation and in both two pole and three pole types. According to the manufacturer there has been no NEMA standard breaker between 50,000 and 100,000 kva interrupting capacity. Roller-Smith Co., 12 Park Pl., New York City.

**Wires and Cables.**—Bulletin, 4 pp. Describes various types of insulation and coverings; rubber jacketed, lead sheathed and varnished cambric cords and cables, together with weather-proof wire and cable, armored bushed cable, Cresflex, a non-metallic sheathed cable, parkway cables and special cables. Data on building wire and cable and conduit sizes for rubber-covered building wire are set up in convenient table form for ready reference. Crescent Insulated Wire & Cable Co., Trenton, N. J.

**Lubrication Studies.**—A series of effectively illustrated, large page booklets entitled "Panorama of Lubrication," described as "an educational series, dedicated to executives, engineers, salesmen and students whose interest in the subject of lubrication demands simplicity." The first three issues of the series, each 24 pages, are now available: 1—The Fundamentals of Lubrication; 2—Lubricating Friction Type Bearings; 3—The Modern Motor Oil. The latter details refining processes and the sources and nature of crude oils. Shell Petroleum Corp., Shell Bldg., St. Louis, Mo.

**New Circuit Breaker Feature.**—Bulletin 237, 6 pp. Describes the new thermo-magnetic overload feature, applicable to all a-c types of I-T-E motor-protecting circuit breakers and available for all types of a-c motors up to 1,000 hp., 550 volts. The new feature discriminates with unfailing accuracy between normal and unsafe overloads. It permits full-voltage starting even when the accelerating period is unusually long and the inertia load exceptionally heavy. The breaker is tripped before dangerous temperatures are reached in a motor or in the device itself. With overcurrents of short-circuit intensity, tripping is instantaneous. I-T-E Circuit Breaker Co., 19th and Hamilton Sts., Philadelphia, Pa.

Accepted for mailing at special postage rates provided for in Section 1103, Act of October 3, 1917, authorized on August 3, 1918. ¶ Publication Office: 20th & Northampton Streets, Easton, Pa. Editorial and Advertising Offices at the headquarters of the Institute, 33 West 39th Street, New York

### The Cover

Mighty Niagara, a point of interest for those attending the Institute's North Eastern District meeting in Buffalo, N. Y., May 4–6

# High Lights

**Summer Convention.** Milwaukee and vicinity and the State of Wisconsin offer unusual opportunities to those wishing to combine attendance at the Institute's 1937 summer convention with their vacations. The program includes 10 technical sessions and one special "general" session. The usual sports competitions and a splendid array of interesting inspection trips and entertainment features provide a well-rounded program (*pages 635–9*).

**Employment of Engineers.** During the 5-year period from 1929 to 1934, the number of persons in the engineering profession increased by 25 per cent, which was much in excess of available engineering employment opportunities. This is one conclusion reached by the United States Bureau of Labor Statistics in analyzing the employment data obtained in its 1935 survey of the engineering profession (*pages 524–31*).

**Some Engineering Contributions.** In 1920, 41 million tons of coal was required to produce 27 billion kilowatt-hours of electric energy in power stations in the United States; in 1934 the same amount of fuel produced 57 billion kilowatt-hours. This is but one of the many engineering contributions to society which have resulted in providing the public with a dependable supply of electric power at low rates (*pages 518–23*).

**Student Activities.** Representative of activity of Student Branches throughout the Institute's various Districts, were the annual Student Branch conference of the Southern District (*pages 641–2*) and the annual convention of Student Branches in the eastern portion of the Middle Eastern District (*pages 640–1*), both of which were held recently.

**Cable Saturants.** Physical and electrical properties of several saturants for paper-insulated cables have been investigated in a series of tests, and correlations made with the viscosity index and chemical composition of the oils and resins. Gaseous ionization in insulation voids was found to exert pressure and accelerate oxidation (*pages 566–76*).

**Lightning-Arrester Performance.** From manufacturers' data pertaining to breakdown characteristics of lightning arresters under standard rates of voltage rise, and $IR$ drops for crest values of current of 1,500, 3,000, and 5,000 amperes, the protective characteristics of 3- to 15-kv line-type arresters have been determined (*pages 576–77*).

**Magnetic Contactors.** Because of some fundamental limitations, the use of magnetic contactors as commutating devices for the application of power during brief periods has not been entirely satisfactory. A method of avoiding these limitations, and at the same time providing great accuracy of timing the periods of power application, has been evolved (*pages 583–8*).

**Sphere-Gap Calibration.** Much progress has been made in extending and revising the calibrations of the grounded sphere gap for both 60-cycle and impulse voltages. A paper in this issue presents some of these revisions, and, in addition, describes the effect of ultraviolet irradiation of the sphere gap (*pages 594–6*).

**Expulsion Gaps.** Guarding overhead power lines against damage from lightning by the use of expulsion protective gaps which conduct the lightning current to ground and break the power current that follows has been practiced for several years. Information obtained from field experience and tests is now available (*pages 551–7*).

**Coincidental Electric Drives.** Individual motors are used in some industrial applications to drive units of a machine that may require either a constant or a varying speed relation among the motors. Principles of operation are given in a general description of this type of drive (*pages 578–82*).

**Economic and Engineering Progress.** The development of the modern economic system has closely paralleled the growth of scientific knowledge, says a well-known authority in discussing progress in the interdependent fields of engineering and economics (*pages 510–17*).

**Motor Protection.** Thermal overload devices such as solder-film or bimetallic-strip relays commonly are used for the protection of a-c motors. Comparison of the proper motor and relay data provides a basis for the determination of adequate overload protection (*pages 589–93*).

**Corona Loss.** Most mathematical formulas for computing corona loss on transmission lines do not agree entirely with observed data for all conditions; therefore, a purely empirical method of computing corona loss has been derived from co-ordination of experimental observations (*pages 558–65*).

**Outages on Shielded Lines.** From the observation that flashover of transmission-line towers with 2 overhead ground wires occurs only when the product of tower-footing resistance and tower surge current exceeds the insulation strength, the probable outages may be determined (*pages 597–600*).

**Police Radio.** Law-enforcement agencies always are concerned with improving their methods of transmitting intelligence. In the last few years municipal and state police departments have turned to radio as the most rapid and effective means of dispatching patrol cars (*pages 532–44*).

**Industrial Lighting.** A broadening of the scientific knowledge of the relations of light to the process of seeing has suggested a new approach to the specification of lighting for industrial processes (*pages 545–50*).

**Year Book.** The Institute's 1937 Year Book is now available to members having use for it (*page 641*).

# DISCUSSIONS

Appearing in this issue are discussions of the following papers:

## Electrical Machinery

Abrasion—A Factor in Electrical Brush Wear—Hessler . . . . . 601
Arc Characteristics Applying to Flashing on Commutators—Hellmund . . . . . 603
Contact Drop and Wear of Sliding Contacts—Baker & Hewitt . . . . . 605
Self-Regulated Compounded Rectifiers—Goodhue & Power . . . . . 606
An Analysis of the Shaded-Pole Motor—Trickey 612
Induction Motors on Unbalanced Voltages—Reed & Koopman . . . . . 621
Capacitor Motors With Windings Not in Quadrature—Puchstein & Lloyd . . . . . 634

## Electrophysics

Expansion Theorems for Ladder Networks—Malti 601

## Power Transmission

Lightning Investigation on a 220-Kv System—II—Bell . . . . . 622
Lightning Investigation on Transmission Lines—VI—Lewis & Foust . . . . . 624
Electrical Characteristics of Suspension-Insulator Units—Dawes and Reiter . . . . . 628
Lightning Protection for Transmission Lines—Gothberg & Brookes . . . . . 631
First Report of Power System Stability—Subcommittee Report . . . . . 632

## Tensor Analysis

Dyadic Algebra Applied to 3-Phase Circuits—Sah 610
Complex Vectors in 3-Phase Circuits—Sah . . 610
The Tensor—A New Engineering Tool—Boyajian 614
Tensor Algebra in Transformer Circuits—Bewley 614

# The President Meets the Sections

"ON what subject would you like a message from the president?" I asked 2 young engineers who have recently joined the AIEE. Their answer was, "Tell us about the work of the other Sections." So I was led to review my pleasant travels of the last 9 months, and the many Sections I have been privileged to visit.

Why does the president visit the Sections? Primarily because they invite him to do so; and it is his pleasure and duty, as far as possible, to accept these invitations from those who have elected him. It is certain that these visits inspire him and acquaint him with the activities and needs of the organization. It is hoped that from him each Section visited learns of national affairs, of the work of the other Sections, of projected policies, and from him receives some degree of inspiration, leading to greater Section activity.

The courtesy, hospitality, and interest shown by every Section visited, have made this phase of my Institute activity one which I long shall remember. In the last 9 months, I have visited 33 Sections and 18 Branches, and attended 2 conventions and a District meeting. In the next 4 months, I shall visit 11 Sections and 4 Branches, and attend a District meeting, a District student convention, and a national convention. While visits to Sections are desirable, inspiring to the President and, I hope, to the Sections, visits to Branches I consider even more desirable, for within the Branches are found the engineering leaders of the future.

Last November I told you something of my early trips and my pleasure in attending the twin meetings at Knoxville and Chattanooga, which initiated the active participation of the East Tennessee Section in Institute affairs. October and November were marked by a Western trip, with meetings at St. Louis and Kansas City, Mo., on the way to the South West District meeting at Dallas, Texas. The automobile drive from Kansas City to Dallas, with E. T. Mahood, past chairman of the Kansas City Section, and Mrs. Mahood, familiarized me with the great Southwest, and permitted a preliminary social visit with the officials of the Oklahoma City Section. Reviewing the 3-day Dallas meeting, I was indeed surprised that 6 of the 9 meals were in the company of Vice-President L. T. Blaisdell. This same vice-president accompanied me to the Houston Section meeting and, returning with me to Dallas, drove me to the Oklahoma Section meeting approximately 350 miles away. The following morning I inspected the Oklahoma oil field and saw a 110-horsepower motor, 10 inches in diameter and 20 feet long. Guided by the proverb "all work and no play," the afternoon was devoted to golf.

In quick succession followed enthusiastic Section meetings at Salt Lake City and Denver, with Branch meetings at the Universities of Colorado and Utah.

Stealing a Sunday en route from Denver to Los Angeles, I realized a 40-year-old ambition: a trip to the bottom of the Grand Canyon on mule back. It is highly recommended. In Los Angeles a noonday meeting with the Section executive committee preceded a joint meeting with the technical societies of Los Angeles, addressed by Dr. Von Kleinschmid, president of the University of Southern California, and myself. I strongly favor these joint meetings with other engineering societies.

A plane trip to San Francisco made possible a Branch meeting at the University of California, with a Section meeting the following evening. Then came Portland, Seattle, Vancouver, Spokane, with Branch meetings at Washington State College and the University of Idaho. At Bozeman, there was a meeting of the Montana State College Branch at 11:00 a.m., luncheon with the faculty, and a Montana Section meeting in the evening. The following day another lifetime ambition was realized. Professor J. A. Thaler and his delightful wife drove me to Yellowstone Park. Over a railroad electrically operated through its mountain divisions, I reached Milwaukee, Wis., and was entertained at lunch by the entire 1937 summer convention committee. In the evening was the joint Milwaukee-Madison Section meeting at the Allis-Chalmers Club. (Do not miss the Milwaukee convention this June.)

The trip back to Cleveland was enlivened by a luncheon with the Chicago Section executive committee, and attendance at the regular Chicago Section dinner meeting where, fortunately, I had the opportunity of hearing another speaker.

Participation in Section meetings at the neighboring cities of Pittsburgh and Erie, Pa., was easily accomplished.

Going to the New York winter convention by the way of a Toronto Section dinner meeting was a most pleasant experience, and approaching Miami, Fla., by the way of a Caribbean cruise was equally delightful. (See message in March issue.)

Such an extensive Section as Florida required 2 meetings, at Miami and Jacksonville, one of which unfortunately was missed because weather conditions prevented the scheduled sailing of a plane.

The best method of transportation through Florida was found to be by the use of a Ford car rented in Miami and delivered at Jacksonville; a stop was made at Gainesville for a meeting of the University of Florida Branch and a radiobroadcast.

By a zigzag route and close co-operation from Institute members, we attended an all-afternoon Section meeting at Raleigh, N. C., a pre-organization meeting at Columbia, S. C., visited the Broad River power development, met with the Branches at Clemson College, Georgia School of Technology, Alabama Polytechnic Institute, and the University of Alabama, and addressed the Atlanta and Alabama Sections at enthusiastic dinner meetings. National Secretary Henline joined me at Raleigh, and ably participated in all the meetings that followed.

The March trip through New England was distinctive. It was completely arranged by Vice-President A. C. Stevens and District Secretary R. G. Lorraine. They, with Mr. Henline and myself, made up an official visiting delegation. Through their efficient organizing, we were able to attend 6 Section meetings in 5 days: Connecticut, Lynn, Boston, Providence, Worcester, and Springfield. Three of these were joint Branch-Section meetings. This was one of the most inspiring trips of the year.

Ahead of me is the privilege of attending the meeting of the North Eastern District at Buffalo, N. Y., the Student Branch convention of the North Central District at Brookings, S. D., the Milwaukee national convention, as well as visiting the following Sections: Chicago, Philadelphia, Sharon, Baltimore, Minneapolis, Cincinnati, Rochester, Ithaca, and Lehigh Valley. Last, but not least, is the annual meeting of my own Section, to be held in Cleveland on May 20.

This is the story of my travels, and the roster of the Sections and Branches with which I have been fortunate to become acquainted. Next month I shall take the opportunity of telling you what I learned of these Sections and Branches, their activities, and their plans for the future. I hope that each Section and Branch may receive help and inspiration from the record of what the other Sections and Branches are doing.

# Engineering Progress and Economic Progress

By HAROLD G. MOULTON
President, The Brookings Institution

**The advance of engineering has a vital bearing upon economic progress; in turn, though perhaps less obviously, the operation of the economic system largely determines the rate at which new engineering discoveries may be applied in the actual production of wealth. From this point of view Doctor Moulton discussed progress in the interdependent fields of engineering and economics in the Eleventh Steinmetz Memorial Lecture,* full text of which is presented here.**

ENGINEERING is concerned with the application of scientific knowledge to the processes of wealth production. Economics is concerned with the basic resources and factors upon which wealth production depends and with the forces and institutions that influence or control the operation of what we call the economic system. It is readily apparent, therefore, that the advance of engineering has a vital bearing upon economic progress. In turn, though perhaps less obviously, the operation of the economic system largely determines the rate at which new engineering discoveries may be applied in the actual production of wealth. This truth is brought sharply to our attention in periods of acute business depression, when the introduction of improvements of demonstrated value is indefinitely deferred, and the process of discovery and invention itself is slowed down; but even in times of prosperity the installation of new methods and devices is not infrequently retarded because of general economic considerations.

In view of this intimate relationship between engineering and economics, it affords me especial pleasure to join with you in considering problems of mutual interest on a forum dedicated to the memory of a great scientist and engineer, who was at the same time deeply concerned with the relationship of his profession to the development of civilization.

## Science and Economic Development

The development of the modern economic system has in fact closely paralleled the growth of scientific knowledge. By way of introduction, let me briefly recapitulate the history of the last 3 centuries in terms of engineering and economics. Though not commonly realized, developments in the field of the so-called natural sciences paved the way for the modern political and economic system.

It was in the sixteenth and seventeenth centuries that such men as Galileo, Kepler, and Newton discovered and formulated the basic laws that operate in the physical world. In due course these scientific discoveries came to exert a profound influence upon men's ideas in other realms of thought. Was not man, the creation of God, as much a part of and subject to an ordered universe as the physical earth on which he had his setting?

The view arose that there existed a system of *natural law* which, if it were not interferred with by governments or other human institutions, would always lead to progress. Blackstone, the great English jurist, for example, contended that there had been established by the Creator a simple system of natural law or ethics, and that the constitution and frame of humanity had been so contrived that if we but pursued our own "true and substantial happiness" we could not fail to be in tune with the universe of nature. Moreover, according to Adam Smith, the great Scottish philosopher who founded a system of thought known as political economy, each of us in pursuing his own welfare and happiness is led as by the Divine Hand to promote the welfare of his fellowmen.

This new philosophy of *natural law* led in due course to practical results of great significance. First, innumerable laws restricting the freedom and the initiative of the individual were repealed. Second, industry and trade were relieved from a multitude of hampering regulations. Third, national boundaries came largely to be ignored through the removal of barriers and restrictions against the free international movement of trade and currency, and against the migration of people from country to country. The conception of a world society was born, in which men should be free not only to develop their individual capacities to the utmost, but also to live in whatever spot on the globe they desired and to conduct their business operations without reference to any national boundaries.

All this, it may be seen, constituted a *theory* of economic and social evolution or a *science of society*. New conceptions resulting from discoveries in the field of natural science came in time to be the foundations of social science. Moreover, the practical application of scientific discoveries

* Eleventh Steinmetz Memorial Lecture delivered by Doctor Moulton under auspices of the Steinmetz Memorial Foundation at a meeting of the AIEE Schenectady, N. Y., Section on April 6, 1937.

HAROLD G. MOULTON received the degree of doctor of philosophy from the University of Chicago in 1914, and was a member of the faculty until 1922. At that time he resigned the post of professor of political economy to become director of the Institute of Economics, Washington, D. C. The institute was amalgamated with the Institute for Government Research and the Robert Brookings Graduate School of Economics and Government in 1927, and Doctor Moulton was appointed president of the newly formed Brookings Institution. He is the author of many books on economic and allied subjects.

to the processes of production gave to the business organizer an ever expanding scope for his enterprise. One need cite only the influence of steam, electric, and gasoline power on transportation development to indicate the significance of science in broadening the area over which business enterprise can successfully operate.

## Rising Standards of Living

In the short interval of time since the founding of the American Republic, man's power over nature has been increased vastly more than in all preceding history. If we were to let the span of human history be represented on the face of a clock, the period elapsing up to the last 2 centuries would be roughly the equivalent of the time from noon to 10 minutes before 12 midnight. The last 10 minutes would represent the period during which science, engineering, and the system of free business enterprise have been dominant. Economic progress during these last 10 minutes has greatly exceeded that of the preceding 710 minutes. The standards of living of the masses today, notwithstanding an extraordinary increase in population, are higher than those of the classes of former times.

Statistical measurements as to the rate of economic progress are available only for comparatively recent years. But in the era of expansion from 1900 to 1929 production per capita in the United States increased by about 38 per cent; and there was a 13-per cent shortening of the hours of labor. In manufacturing industry the increase in efficiency was, of course, much greater. In the 7-year period from 1922 to 1929 efficiency in manufacturing increased by 25 per cent.

## Retardation of Economic Growth

Despite the remarkable developments that have occurred under the capitalistic system, no one who thoughtfully surveys the economic history of recent times can well be complacent. Not only do we have periodic depressions which destroy accumulated wealth and income; but even at best the performance of the economic system leaves something to be desired. It would seem, when one stops to think carefully about it, that the rate of economic progress ought to be a constantly accelerating one—since each new generation starts with larger margins above the requirements for subsistence and builds upon greater accumulations of scientific knowledge and experience. Certain observed tendencies, however, are disquieting. Apart from the long periods of business depression and stagnation, one notes that the older and more mature a nation becomes the less rapid seems to be the rate of economic progress. In any event, the question sharply presents itself: Do conditions develop in the operation of the economic system which seriously retard further applications of engineering knowledge, and hence further progress?

It has been with a view to throwing light upon this basic question that the Brookings Institution in recent years has carried through a series of investigations under the broad general title of the distribution of income in relation to economic progress. Some of the results of these studies are here brought to your attention by means of a series of charts.

Before presenting these charts let me briefly recapitulate some of the conclusions reached.

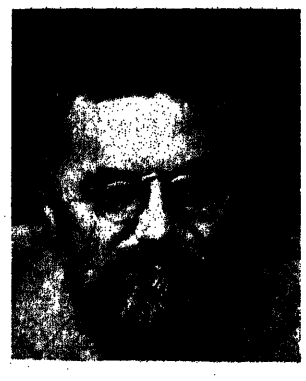
1. It was found that there is a substantial margin of unused productive capacity, even in periods of prosperity. In the boom period, 1925-29, the economic system as a whole was not producing at more than 80 per cent of capacity; we did produce about 81 billion dollars worth of goods and services in 1929, but we might have produced about 96 billions.

2. The failure to use all of our productive capacity could not be attributed to an existing excess of production as compared with human needs. Production in the United States in 1929 amounted to only about $660 per person—about $2,600 per family. It would have required a vast increase in output to provide reasonably satisfactory standards of living for the American people.

3. The failure to produce more was attributable to an inability to find markets adequate to absorb full productive capacity.

4. The lack of adequate markets reflected inadequate purchasing power on the part of the masses of the people having large unfulfilled desires.

5. The inability of the masses to buy larger quantities was a result of the discrepancy between their money incomes and the prices at which goods were offered in the markets.



This last point will be developed at some length in the course of the discussion, but first let us have a brief look at the charts that bear upon the conclusions just stated (figures 1 to 9, inclusive).

## Effects of the World Depression

Figures 1 to 5 relate chiefly to the predepression situation and are concerned solely with the United States

---

THE Steinmetz Memorial Lectures were established in 1925 by the Schenectady Section of the AIEE, as a means of recalling periodically to the members of the Section and the general public the personality and achievements of Charles Proteus Steinmetz. The interest aroused by these lectures has been such that his friends and admirers have raised an endowment fund to place the memorial on a permanent basis, independent of the future success of the Schenectady

Section of the AIEE. This fund will insure that the memory of Doctor Steinmetz will be recalled frequently in a way most appropriate to commemorate a man who combined a lovable personality and a broad human interest with the highest grade of scientific attainment. Previous lectures have been delivered by M. I. Pupin, E. J. Berg, R. A. Millikan, Max Mason, D. S. Kimball, W. E. Wickenden, K. T. Compton, C. E. K. Mees, R. E. Doherty, and Gerard Swope.

The next series of charts (figures 6 to 8) is focussed directly on the effects of the depression upon economic progress both in the United States and the world at large.

All the diagrams thus far mentioned fail to portray fully the effects of the depression because the factor of general growth is not included. With the population of the United States in 1936 about 5 per cent greater than in 1929—indeed with the population of working age about 9 per cent greater—we should expect a proportionally larger output than in 1929. In fact, had it not been for the depression we might have expected the supply of capital and the efficiency of production to continue at something like its usual rate of increase, with a corresponding expansion in per capita output. The next chart (figure 9) indicates in a rough way the effects of the depression by comparing actual production since 1929 with the amount of production that we would have had if predepression trends had been continued.

Figure 9 shows that in 1936 the average production (including agricultural and mineral as well as manufacturing) should have been about 20 per cent higher than in 1929; in fact, it was less than 90 per cent of the 1929 level. In other words, the output was not quite $^3/_4$ as great as it would have been had there been no interruption to progress.

The results of this curtailment of production are of course clearly revealed in the statistics of national income.

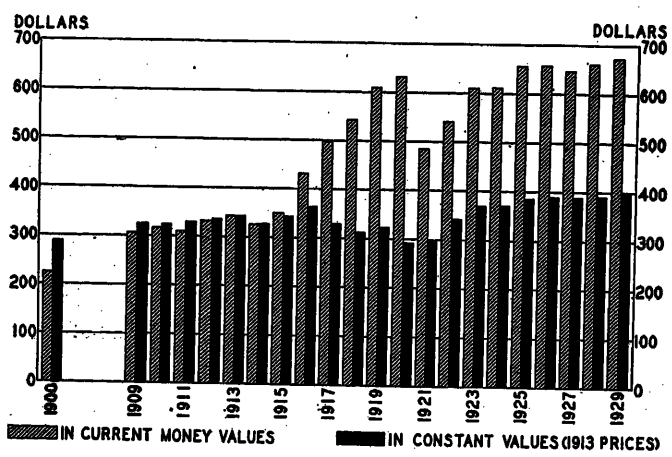


**Fig. 1. Per-capita income from current production**

This diagram reveals the growth of national income over the 30-year period of expansion from 1900 to 1929. As already stated, the increase amounted to about 38 per cent per capita, while at the same time there was a 13-per cent reduction in working hours. The cross-hatched bars indicate the amount of income as measured in actual dollars. The dark ones indicate the amount when adjustment is made for the fluctuations in commodity prices. It is of course the latter that represent the real growth in income

Had there been no depression and had the prewar trend of production continued, the total national income in 1936 would have been more than 97 billion dollars (as measured by 1929 prices). The actual income in 1936, including that received by individuals engaged in work relief, was only about 70 billions (again as measured by 1929 prices).

## Engineering and Economic Fundamentals

In the light of these graphic illustrations of economic retardation, we may now return to the discussion of engineering progress and economic progress. We shall center our attention not so much upon the phenomenon of the depression itself as upon the longer-run persistent factors or tendencies that affect the rate of progress.

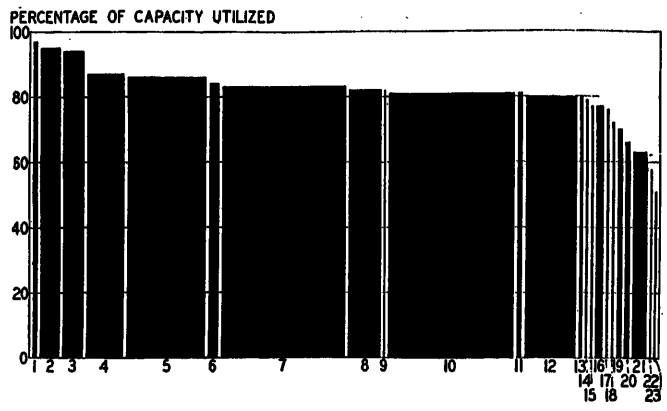

**Fig. 2. Utilization of mineral capacity**

This diagram indicates the percentage of capacity that was actually utilized in the various divisions of the mineral industries in 1929. Each bar represents a particular division of the industry, the width indicating roughly its relative importance. The highest degree of utilization is found in electrolytic copper refineries and the lowest in black powder mills. It may be observed that in the main the utilization was in the neighborhood of 80 per cent. The large area labeled 5 is petroleum refineries; 7 is bituminous coal mines; 10, crude oil; and 12, anthracite collieries

The engineering attitude always has been direct and fundamentally simple. Moreover, its validity is not open to challenge. It is based upon the elementary assumption that the function of engineering is to apply the new knowledge that is continuously accumulating to the improvement of productive instruments and processes, with a view to increasing the efficiency of mankind in adapting natural resources to the satisfaction of human wants. Increasing efficiency simply means producing more with the same effort—in consequence of which standards of living will be raised.

If it be agreed that the engineering conception of progress is indubitably true, then it must follow that the test of an economic system is to be gauged by its efficiency in promoting the engineering ideal. The system of private business enterprise, as it has often been expounded by both professional economists and business leaders, does in fact embody this engineering conception of progress. The nature of the problem is complicated, however, by the fact that under the capitalistic system production is financially organized and controlled.

Business managers use money in the hiring of labor and

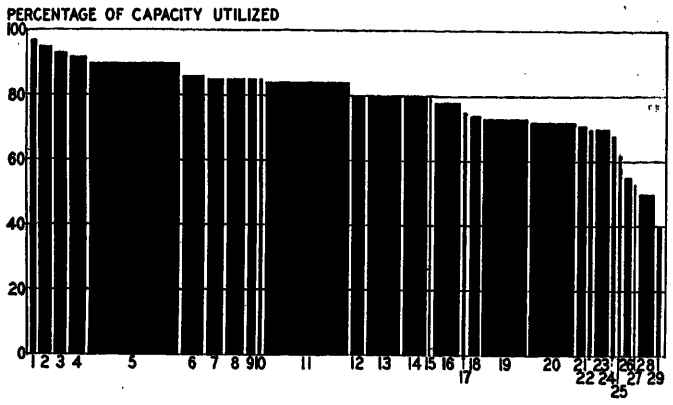

**Fig. 3. Utilization of manufacturing capacity**

This shows the degree to which manufacturing capacity was utilized on the average in the 5-year period from 1925 to 1929. A somewhat wider range is indicated here, but again the general average is not far from 80 per cent. The highest degree of utilization is in full-fashioned hosiery establishments, and the lowest in locomotive plants. The large area, 5, is printing and publishing; 11 is automobiles; 13, cotton manufactures; 14, boots and shoes; 16, men's clothing; 19, rolled-steel products; and 20, lumber

in the purchase of materials and supplies, and they sell their products for money. The aggregate amount of money received from sales of course must exceed the aggregate disbursements if profits are to be realized. Thus, business has its setting in a structure of monetary costs, prices, and profits; and the economic requirements for progress must accordingly be analyzed in these terms. The incentives and mechanisms by which the competitive system has been supposed to insure rapid economic progress and higher standards of living may be summarized briefly as follows:

1. It is contended that each business manager naturally stands to gain by increasing efficiency and thereby reducing costs. He may accomplish this by the construction of a larger and more efficient plant, by the installation of better equipment, by the introduction of superior internal management, by improved methods of marketing, by integrating various stages in the productive process, or by a combination of various methods.

2. Having reduced costs of production he is in a position to increase his profits in one or another of 2 ways: He may continue to sell at the same price as before, enjoying the advantage of a wider margin between cost and selling price, or he may expand the volume of his business by means of price concessions. It was reasoned that since the increase in efficiency which is responsible for the reduction in costs commonly involved an expansion of productive capacity, and since the maximum economies can be obtained when operating at full capacity, the greatest profits will result if sales are expanded by means of a reduction of prices. In short, increased efficiency makes possible lower prices, while the profit incentive was held to insure an actual reduction of prices.

3. The process naturally involves the continuous elimination of obsolescent or otherwise inefficient high-cost establishments. The industrially fit, as gauged by ability to sell at a minimum price, alone survive; moreover, the efficient of today promptly become the inefficient of tomorrow. A particular business man, firm, or corporation may indeed survive over a long period of years, but only if the production methods employed keep always abreast of changing times. It may be seen that with the system thus operating, standards of living would steadily rise. The progressive reduction of prices as efficiency increases would, of course, constantly increase the purchasing power of the masses—giving them an increasing volume of goods for the same money.

It should be carefully noted that this theory of progress implies that the reduction in money costs must result

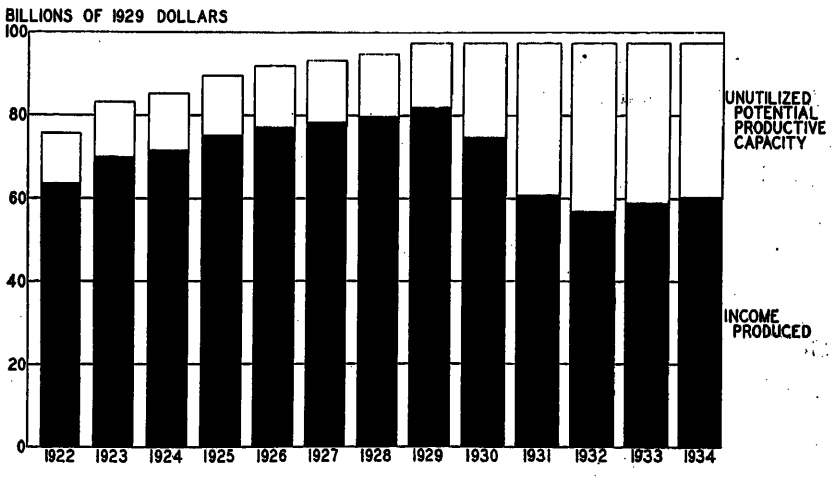

**Fig. 4. Productive capacity and actual production**

Here is a rough picture of the economic loss to the nation over a period of years resulting from our failure to make full use of our productive capacity. The black portions of the bars show the actual income produced in the years 1922 to 1934, inclusive. The upper areas indicate the additional amounts that might have been produced had our resources been fully utilized. For lack of adequate data as to the growth of productive capacity after 1929, the height of the bars has not been extended above the 1929 level. Since in the absence of depression productive capacity would have continued to expand, the diagram materially understates the true situation. A later diagram (figure 9) serves to reveal the indirect losses resulting from the depression

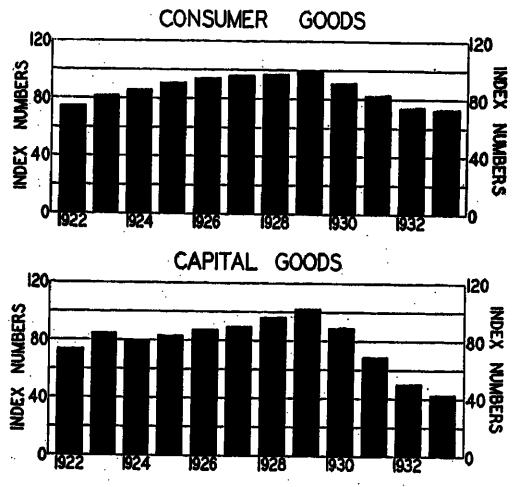

**Fig. 5. Fluctuations in production of consumer and capital goods**

The most striking result of a depression is the extraordinary decline in the rate of construction of new plant and equipment. That is to say, the application of scientific and engineering knowledge to the further expansion of productive capital is seriously impeded. This diagram shows that the amount of new capital construction at the depth of the depression in 1933 was only 40 per cent of that in 1929, being confined almost entirely to replacement as distinguished from new capital construction. Even after 3 years of recovery the rate of capital construction is still far below predepression levels

from increased efficiency rather than from a mere reduction in money wage rates. A reduction in wage rates may indeed lower money costs and prices; but since it neither increases efficiency nor the purchasing power of the masses there is no resulting economic advancement.

In order to reveal more distinctly what is involved in raising living standards in a *pecuniary* society, I would lay down 2 principles as follows:

1. *The process of raising the standard of living of wage earners necessarily involves increasing the spread between wage rates and prices.* That is, a wage earner can increase the volume of his purchases from year to year only if wage rates are increased relative to the prices of the commodities he buys. If he gets more dollars and prices remain unchanged, his purchasing power is expanded; if he gets the same number of dollars and prices decline, his purchasing power is expanded. It cannot be expanded, however, unless the spread between wages and prices is increased.

2. *An increasing spread between wage rates and prices depends fundamentally upon increasing the efficiency of production.* While minor and temporary increases in wages sometimes may be achieved by trenching upon profits, a progressive increase in the wage-to-price ratio depends directly upon the acceleration of technical advancement, improved management, increased labor efficiency, etc. Any practices or policies that tend to work in this direction are economically sound; any that work in the opposite direction are economically unsound.

We may now leave for a moment the discussion of principles and requirements and turn again to the factual record. The great increase in living standards over the past 200 years to which reference has been made has been brought about by increasing efficiency and an increasing spread between wage rates and prices. The statistics of wages and prices indicate that at certain periods increased purchasing power has resulted mainly from wage increases and at other periods mainly from price reductions. Sometimes also improvements in living standards have come about simply by the process of a more rapid rise in wages than in prices.

The trend of wholesale prices in relation to weekly wages over the period from 1800 to 1930 is shown by the next chart (figure 10). It may be observed that wholesale prices show several high peaks occurring in war periods, with fluctuating but generally downward trends in between. Money wages, however, show a persistent upward trend over the period as a whole. In consequence, the general trend of real wages is sharply upward.

For recent years data with respect to wages and prices are more detailed and precise. The next chart (figure 11) shows hourly earnings in manufacturing industries and both wholesale and retail prices of finished manufacturing products for the 15-year period 1932 to 1936.

It may be observed that during the prosperity period of the twenties wholesale prices showed a slight irregular decline, while retail prices remained practically stationery. Hourly earnings increased sharply in 1923 but very moderately thereafter. Real wages, however, did not increase as fast as productive efficiency.

During the course of the depression hourly earnings fell somewhat less rapidly than either wholesale or retail prices. Since the beginning of the recovery period hourly earnings have risen much more than either wholesale or retail prices. In fact, hourly earnings at the end of 1936 were actually above the 1929 level, whereas prices were nearly 20 per cent below.

In concluding this discussion it should be noted again that the benefits of technological advancement may be disseminated *either* by increasing money wages or by decreasing prices. Which of these alternative means is the more effective?

The answer is decreasing prices. The wage increase method enhances the purchasing power of only that portion of the population which works for wages—and this constitutes only about 40 per cent of the entire population. When prices are reduced, on the other hand, everybody is benefited; wage earners, salaried employees, farmers, and professional groups alike are able to get more for their money. This method not only gives a maximum increase

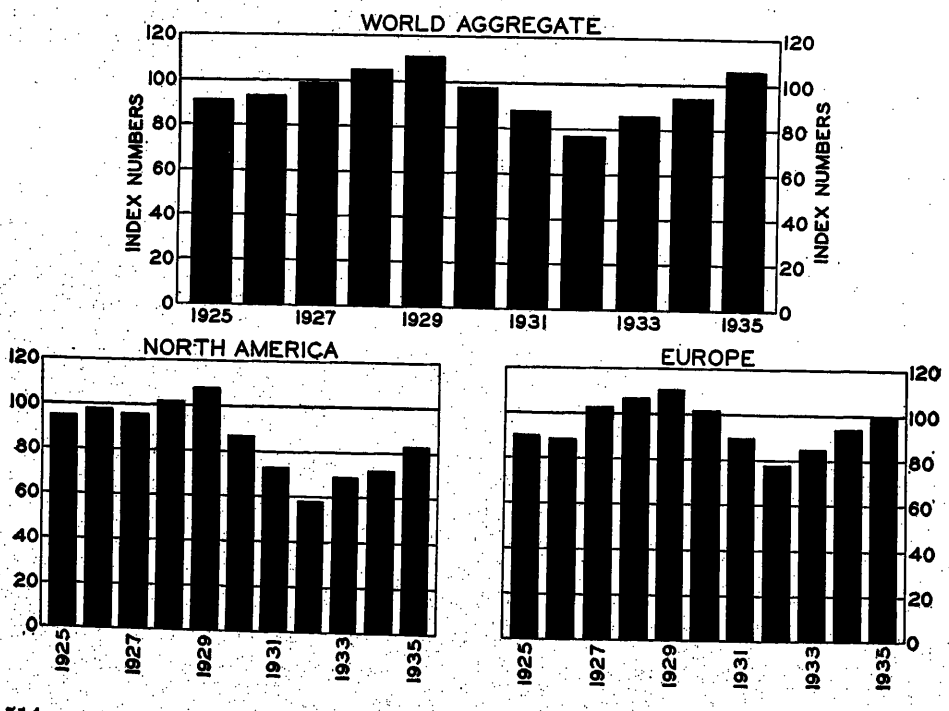

**Fig. 6. World manufacturing activity, 1925–35**

(1925–29 average = 100)

It may be observed that the aggregate volume of manufacturing in the world at large was steadily expanding from 1925 to 1929; that during the next 3 years it fell precipitately, reaching a level substantially below that of predepression years; and that after 3 years of recovery we were still below the level of 1929. Data for the year 1936 are not yet available, but it is probable that the total for that year will be slightly above that for 1929. It should be borne in mind in this connection, however, that world population has meanwhile increased by at least 6 per cent. It will be noted also that the decline was appreciably greater in North America than in Europe and that the degree of recovery has been somewhat less

in purchasing power, but it also serves to maintain a better balance between different divisions of our economic system, particularly between industry and agriculture.

It does not follow, however, from the indubitable fact that the broadest possible dissemination of income is attained through reductions of prices, that this method

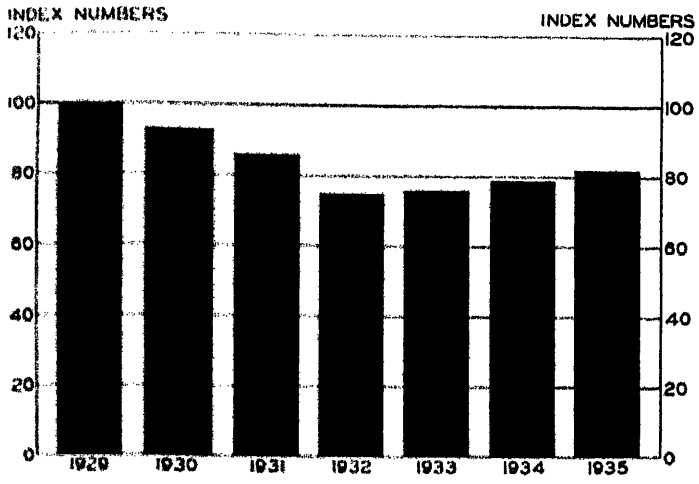

**Fig. 7. Volume of world trade**

The volume of world trade declined from 100 in 1929 to 75 in 1932. In 1935 it had returned to only 82 per cent of the 1929 level, and there was only a moderate increase in 1936. Exchange depreciation and controls, tariffs, and other commercial restrictions, and the drying up of international credit, have served to prevent any material recovery in international trade

must be given sole consideration. Psychological and other practical factors may also warrant wage advances. Profit sharing also may have an important rôle to play. It may be concluded, however, that price reductions—because of the universal character of their effects—should constitute the primary means of disseminating the benefits of technological improvements.*

## Price Restriction Policies

From the preceding discussion of the operation of the economic system and the progressive rise in standards of living, it would almost seem that the operation of the economic system is highly satisfactory. But such a conclusion is obviously not warranted in the light of the earlier discussion of the ineffective utilization of productive capacity. The truth of the matter is that the price mechanism of increasing purchasing power does not always freely operate.

Over the last 50 years interferences have been developing to the free functioning of the price mechanism. Instead of reducing prices as a means of expanding markets, there has been a growing tendency to maintain prices and to let well enough alone.

* In this brief summary statement only the high points of the analysis can be given. The interested reader may find the full appraisal with supporting data in 4 volumes published by the Brookings Institution under the titles "America's Capacity to Produce"; "America's Capacity to Consume"; "The Formation of Capital"; and "Income and Economic Progress."

Interferences with competitive price movements have occurred as a result of the development of at least 3 major types of business organization. The first is the unified monopoly or industrial combination under single management. The second, found chiefly in Europe, is the cartel or "collective monopoly" under which there is group control of production with a view to stabilizing prices in a given industry. The third is the trade association which seeks, usually through informal co-operation, to stabilize certain conditions within particular industries without interfering with the control of production. There are, of course, many different types of trade associations, and not all are able to exert an influence upon prices; but, by and large, trade associations consciously or unconsciously promote price stability. These associations, unlike consolidations, have generally been viewed with favor by the United States government as a means of stabilizing business.

The results of these policies have been most clearly manifested in the decade of the twenties. This was a

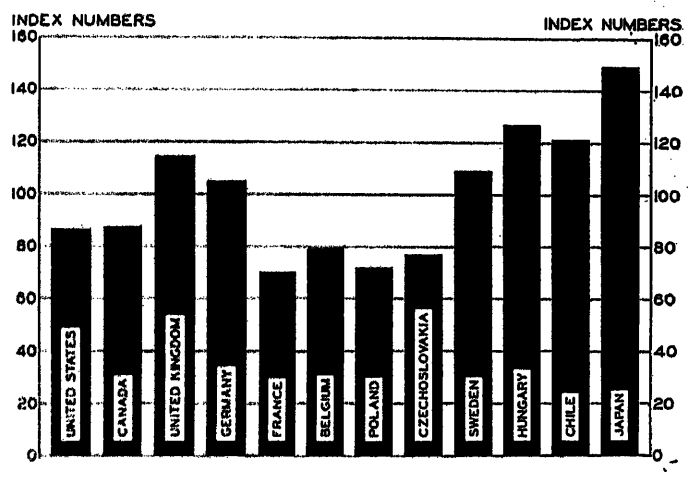

**Fig. 8. Industrial production in selected countries**

In this diagram the output in the year 1929 is taken as 100. Several of the countries included, notably Japan, Hungary, Chile, and the United Kingdom, show production in June 1936 at a level substantially above that of 1929. The United States and Canada stand in an intermediate position, at about 85 per cent, while France, Belgium, Poland, and Czechoslovakia lag materially

period of remarkable advancement. Both the amount of capital and the efficiency of its use increased in nearly all lines of production. In manufacturing industry generally the increase in efficiency was something like 25 per cent. But the benefits of this increasing efficiency were not automatically passed on to the masses of consumers either through the medium of proportional wage increases or proportional price reductions. Wholesale prices of manufactured commodities declined a scant 5 per cent and retail prices did not decline at all. The rate of profits showed a considerable increase during these years. During the recovery period from the beginning of 1934 until the last quarter of 1936 the wage-price mechanism appeared to be working in a very satisfactory manner. As has already been revealed, prices of manufactured goods

fell somewhat, while hourly earnings rose materially. The result was a substantial increase in the wage-to-price ratio. Since this improvement in the wage-to-price ratio was matched by a more or less corresponding increase in efficiency, profits were not reduced. On the contrary, the fuller utilization of capacity that came with an expansion in the total volume of business served to increase the net income of corporations.

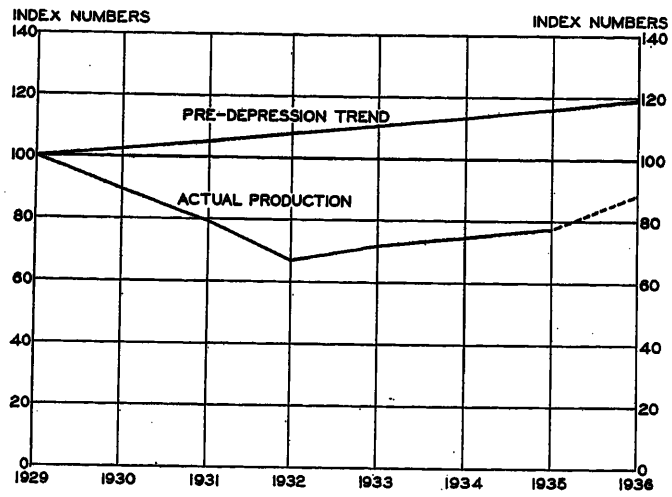

**Fig. 9. Actual production compared with predepression trends**

The upper line is an extension of the predepression trends of production from 1929 to the end of 1936. The lower line shows the actual production, the figures for 1936 being estimated as shown by the dotted projection of the line

## Current Trends

At the end of 1936 the economic situation appeared in many ways exceptionally favorable. Production was steadily increasing, purchasing power was being broadly disseminated among the masses, speculative business activity was not in evidence, inventories remained low, and the general balance between production and consumption was satisfactory. Moreover, there existed clearly defined production requirements adequate, as some studies have shown,* to absorb all the unemployed.

In recent months, particularly since February, the situation has changed in one vitally important respect. Not only have prices of raw materials been rising, but we have had sharp increases in wage rates. These wage increases, ranging from 20 to upward of 30 per cent, have not been related to increases in efficiency. Partly because of this fact, but also in part because of shortsighted industrial policy, the prices of manufactured products are being rapidly advanced. While it is too early to make reliable comparisons of the precise degree to which wages and prices respectively have advanced, there is apparently a strong disposition to assume that prices must be raised in at least equal proportion to the wage advances. The requirement obviously is to restrain the price increases just as much as possible, in order that purchasing power may not be undermined.

The possible effects of the sharp increases in wages and industrial prices must be viewed with apprehension, for they are laying the basis for an old-time vicious spiral of inflation. Rising costs lead to rising prices, and higher prices in turn lead to further advances in wages, costs, and prices. Moreover, a new maladjustment disruptive of balanced relationships is being introduced into the economic situation. While the particular labor groups that receive higher wages may stand to gain for a time, and while the industries in question may temporarily pass on the higher costs to consumers, further extensive expansion appears to be threatened.

The advance in the prices of such basic products as iron and steel and other metals, and building materials, may well serve as a direct impediment to the expansion of production in certain very important lines. The financial condition of the railroads has only recently improved sufficiently to permit extensive physical reconstruction of properties; but now with the prices of steel rising rapidly and railway wage increases also in immediate prospect, it

* See "The Recovery Problem in the United States," published by the Brookings Institution.

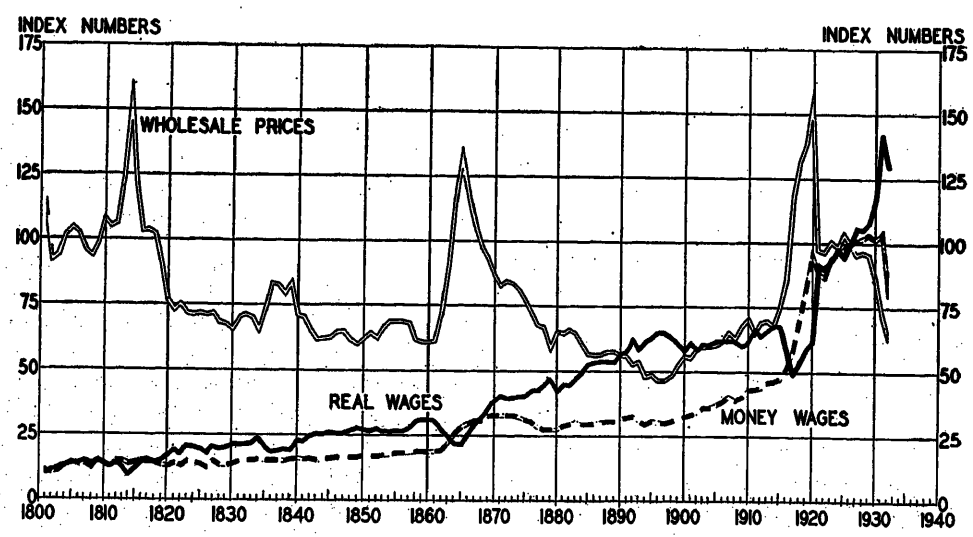

**Fig. 10. Movement of wholesale prices and weekly wages**

The upper line indicates the movement of wholesale prices; the lower one the movement of money wages; and the middle the trend of *real wages* as measured by the relation of prices to wages

is doubtful whether the railroads will be able to carry out the comprehensive programs of rehabilitation that have been prepared. Similarly, the building of new houses, apartments, and other structures may well be held in check by the rising prices of building materials. If this happens, the recent trends will have served to prevent the absorption of the unemployed and the attainment of the higher standards of living which are so greatly desired.

It may be noted also that large sections of the population would soon suffer as a result of a rapid rise in prices, such as: (1) the farmers who do not work for wages; (2) individuals who are working for fixed salaries; and (3) those living on incomes from investments. All these number more than 50 per cent of the total population. Perhaps the most serious phase of the problem relates to the disparity that may again result between industrial and agricultural prices. This is one of the reasons why the government has become so seriously concerned over recent developments.

## Temporary Stimulating Effects

One must note, however, that the adverse effects upon production may be considerably delayed. This is because a rise in prices usually provides an immediate stimulus to industrial activity. With prices going up, business men and others hasten to place orders and buy extra quantities in order to be ahead of the price advance. This expansion of orders accelerates business activity and for a time increases the demand for labor. This expansion of demand in turn serves to increase the demand for products and to raise prices more rapidly. In due course, however, this process serves to intensify the disturbance in price relationships in the different parts of the economic system.

Profits that result from increasing efficiency and an expansion in the total volume of business are soundly based, but profits derived merely from advancing prices are not. Rising prices may indeed stimulate an increase in production and bring on an industrial boom; but since the buoyant activity that results merely from price increases is not accompanied by a corresponding expansion in the purchasing power of the masses, it is not self-sustaining.

It should be clear even from this brief and inadequate analysis of the factors and forces involved in the operation of the economic system that we cannot hope to have economic progress commensurate with the potentialities opened up by modern science and engineering unless governmental, industrial, and labor policies alike are based upon knowledge and understanding of economic fundamentals. The paramount need is for the development and adoption of policies that will promote ever increasing efficiency and ever rising standards of living.

Instead of having reached the limit of progress under the capitalistic system, we should be merely on the threshold of economic advancement. Building on the economic accumulations of the past and on the foundations of modern science, we should be able to look forward to a rate of economic progress in the future that would dwarf anything known in the past. The problem is simply one of the recognition of certain fundamental requirements and the operation of the economic—and political—system in the light of those requirements.

## The Road to Progress

In conclusion I would summarize the fundamental requirements for sustained progress in the following terms:

There must be constantly increasing efficiency in production on the part of both labor and capital. Only by everlastingly improving technical processes and lowering the costs of production can we obtain progressively higher standards of living. To try to accomplish this result in any other way means simply tugging in vain at our collective bootstraps.

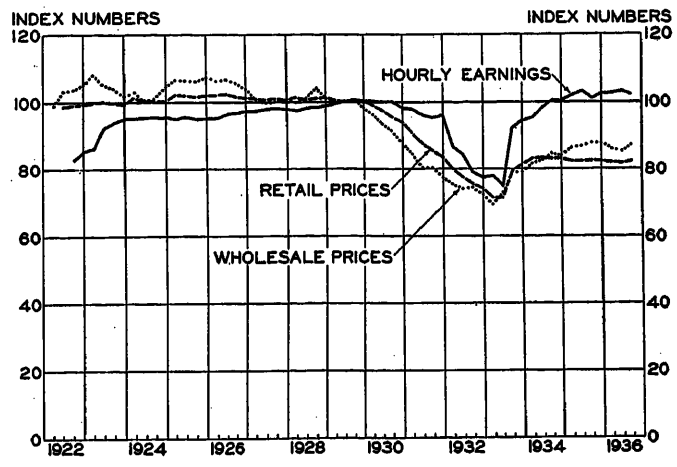

**Fig. 11. Hourly earnings in manufacturing and prices of finished manufactured products**

As efficiency is increased, the benefits must be broadly disseminated among the masses by means of high wages, low prices, or a combination thereof. This is essential for a double reason:

First, it is a fundamental requirement for social and political stability and the well rounded growth of a democracy. It is doubtful indeed if any economic or political system can permanently maintain itself unless it does maintain the goal of the greatest good for the greatest number.

Second, a broad dissemination of the benefits of technical progress is necessary to provide the market demands for an expanding industry. Under our capitalistic system we produce to sell goods in the market. If we increase capacity to produce without correspondingly increasing the capacity of the masses to purchase, we simply reach an impasse. Production schedules have to be restrained, with an accompanying retardation of the rate of economic progress.

Industrial growth, development, progress, require the expansion of consuming power step by step with the expansion of producing power. To put the matter in the simplest possible terms: Growth in the economic organism like growth in any other organism must proceed from the deepest and strongest possible rootage. It must rest on the expanding well-being of the entire population.

# Some Engineering Contributions to Society

By R. C. MUIR
FELLOW AIEE

**Getting more power from less fuel, and consequently providing the public with a dependable supply of electric power at low rates, is the goal toward which power engineers have aimed for many years. In striving toward this goal, they have made significant contributions to society, some of which are indicated in this article**

RESEARCH and engineering have for their ultimate objectives the improvement of social and economic conditions and the conservation of natural resources. Some of the important advances achieved by power engineers in striving toward these objectives briefly are reviewed in this article. It is hoped that this discussion may give engineers a better appreciation of what they have done in this important field, but at the same time may serve as an antidote to complacency, as there yet remains much to be done.

Figure 1 shows data pertaining to the annual production of electric power from fuel for public use in the United States. In 1920, 27 billion kilowatt-hours were produced with 41 million tons of coal; in 1934, 57 billion kilowatt hours were produced and the coal consumption was just the same, 41 million tons. Thus, engineers have given the public more than twice the electric power without increasing the fuel consumption—a notable achievement in the conservation of fuel resources.

Figure 2 shows the improvement in fuel-power electric stations year by year, the performance of the best stations, and the still further improvement possible with the perfection of the mercury-steam station. As may be noted, it took 15 years for the *average* steam-station economy to equal the economy of the *best* station. Hence, 15 years from now the average steam-station economy might be expected to equal the best of today; in other words, for each unit of fuel used then the electric power produced will be $1^2/_3$ times as great as is produced by one unit of fuel today. Were it possible to have all fuel-burning stations equal to the best, only 26 million tons of fuel would be required to produce the 57 billion kilowatt-hours shown in figure 1 for 1934.

Fuel is only one item in the cost of power, and the engineer has not overlooked other items, the most important of which is reliability or availability factor. Coincident with the improvement in efficiency, the reliability has increased, so that the capacity factor has increased and the power generated per dollar of plant investment has materially increased.

It would be impracticable in this article to cover many of the engineering phases that have brought about this improvement, but the turbine generator is representative of the progress made and the problems confronting the engineer.

One of the most important factors in recent power-plant development is the ability to utilize high-temperature steam: that is, steam at 850 to 925 degrees Fahrenheit. This is permitting an increase in the use of high-pressure steam without resuperheating and its attendant complication, and gives a low-cost, simple, and highly efficient installation.

The ability to use high-temperature steam has been dependent upon the development of alloy steels having high creep strength at high temperatures. Ordinary steels are subject to a slow growth or plastic deformation called "creep" at these temperatures when under any appreciable stress.

This precluded the development, up until a few years ago, of turbines to utilize steam at temperatures higher than 750 degrees Fahrenheit. Now, materials are available that permit a stress at high temperatures of from 3 to 4 times what would have been permissible with older materials. This makes it possible to utilize parts of practicable proportions.

The General Electric Company has developed what might be called a second line of defense against high temperature by building some high-temperature turbines with a "double shell." In this construction, the turbine wheels are surrounded by an inner shell carrying its own bolting flange. This shell in turn is surrounded by a second shell which also is bolted at the horizontal joint. The space between is filled with steam at a pressure of about 40 to 50 per cent of the pressure of the steam in the inner shell and at a temperature 50 to 75 degrees lower. The stresses thus are divided between 2 shells so that each can be made thinner than it would otherwise have to be. Figure 3 shows this principle embodied in an actual design.

One of the most outstanding recent advances in the generation of electric power is the superposition on existing steam plants of high-pressure turbines operating at high back-pressure. These turbines take in high-pressure high-temperature steam, develop a certain amount of power, and discharge the steam from their exhausts into the present steam headers of the low-pressure stations. In this way it is possible to increase the capacity of present stations from 40 to 90 per cent, depending upon conditions.

Theoretically, the increased capacity should require an increased coal consumption of about $^1/_3$ pound per kilowatt-hour chargeable to the capacity so installed. Actually, the increased efficiency of the new boilers required by the superposition so reduces the fuel consump-

Essential substance of an address presented at a meeting of the AIEE New York Section, December 9, 1936.

R. C. MUIR is vice-president in charge of engineering, General Electric Company, Schenectady, N. Y. He is a past-chairman of the AIEE Schenectady Section, and has served on the Institute's committees on protective devices and education.

tion chargeable to the old station as to make the 40 to 90 per cent additional capacity obtainable at no increase in fuel consumption whatever.

Since the additional capacity obtained by means of superposed turbines entails no additional fuel cost, it is in this respect on the same basis as a water-power plant; and since the installation cost is from $1/2$ to $1/3$ the cost of a water-power plant, it can be seen that generating capacity obtained in this way is achieved at a very great economy. That the industry is fully alive to this is attested by the fact that the turbines of this type ordered by public utilities during the past 2 years comprise about $1/3$ the capacity of all turbines ordered by them during that period. The remainder, of course, have been condensing turbines. A typical superposed installation is shown in figure 4.

One of the outstanding recent installations of condensing turbines is at the River Rouge Plant of the Ford Motor Company in Detroit, Mich. In the space originally occupied by 2 12,500-kw turbines, 2 new 110,000-kw units have been installed—9 times the capacity in the same space. The fuel consumption per kilowatt-hour is but 60 per cent as much as formerly.

The design and testing of a new type of steam-generating unit of good efficiency and relatively light weight, and requiring minimum space, recently was announced jointly by the General Electric, Babcock & Wilcox, and Bailey Meter companies. This new unit has been named the "steamotive." In it, steam is generated at high pressure and temperature; and fully automatic control in response to changes in demand has been incorporated. The units are intended for capacities of from 2,000 to 10,000 horsepower.

Two such units already have been built. The first, now in service in the Lynn, Mass., works of the General Electric Company, is used to test marine and other small turbines (see figure 5). It has an output of 21,000 pounds of steam per hour at a pressure of 1,500 pounds per square inch. The other, a completely co-ordinated power-generating plant incorporating the "steamotive" and turbine-generator, with a capacity of 10,000 pounds per hour and furnishing steam to a turbine at 1,200 pounds per square inch and 950 degrees Fahrenheit, is being installed in a small isolated plant of a large industrial concern to supply electric power and low-pressure steam for building heating. Both are oil-fired.

Two oil-fired "steamotive" units, each with a capacity of 40,000 pounds of steam per hour, are now being constructed for the Union Pacific Railroad for driving 2 2,500-horsepower electric locomotives. These units will furnish steam to the turbines at 1,500 pounds per square inch and 950 degrees Fahrenheit.

Indicating the compactness of the "steamotive" unit, the one for Lynn was shipped complete from Schenectady on a railroad flatcar.

Objectives sought in the design of the new equipment are high steam pressure and temperature, minimum weight and size per unit of steam produced, wide range of capacity with ability of the unit to respond quickly to wide variations in load conditions, adaptability to wide range of fuels, completely co-ordinated auxiliaries, completely co-ordinated automatic control, and units of simple design and constructed in sizes small enough to be portable.

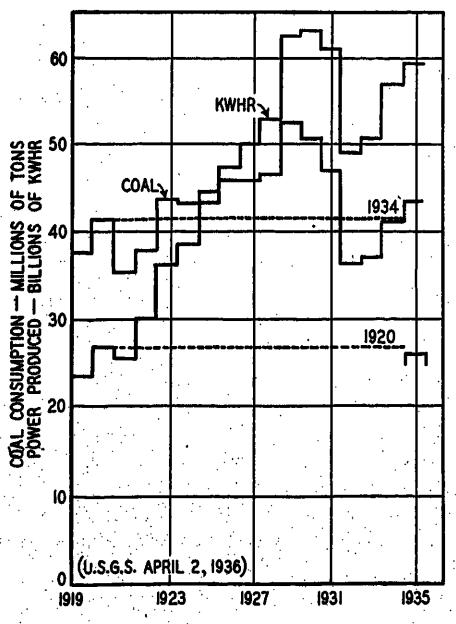

**Fig. 1. Electric power produced for public use, and fuel consumed, in steam-electric stations in the United States from 1919 to 1935, inclusive**

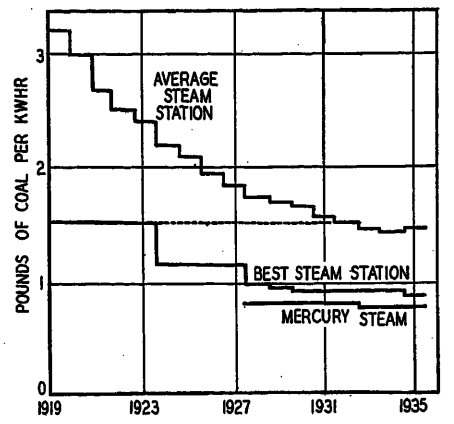

**Fig. 2. Fuel consumed per unit of electric power produced in stations in the United States from 1919 to 1935, inclusive**

## Hydrogen Cooling

A notable example of the value of engineering research in effecting a more economical use of construction materials, and greater economy of machine operation, is the development of hydrogen cooling as applied to rotating electrical machines. For years practically all classes of rotating electrical machinery were cooled with air, chiefly because it was more convenient to use than anything else. Then research showed that this practice was wasteful—that machines would operate more efficiently in gases other than air, and with a greater output per pound of material. Chief among these gases is hydrogen. This gas has a density only $1/14$ that of air, and as a result the windage and ventilation losses of a rotating machine operating in hydrogen would be reduced to $1/14$ of their value in air. The thermal properties of hydrogen also are distinctly superior to those

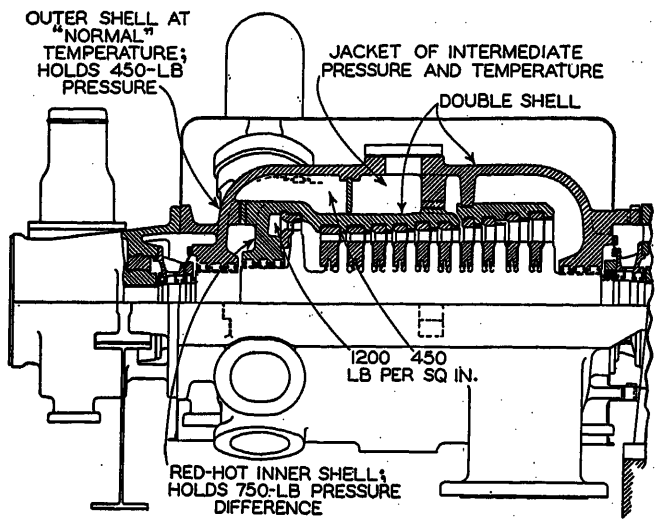

**Fig. 3. Diagram showing construction of double-shell steam turbine for high pressure and temperature**

of air. Hence, by operation in hydrogen, instead of air, up to 25 per cent greater output may be obtained from a machine of given physical dimensions for the same temperature rise of the parts.

The first applications of hydrogen cooling to rotating machines were to synchronous condensers and frequency changers. So successful have these applications been, that in the past 8 years 17 hydrogen-cooled machines of these types, having a combined capacity of nearly 500,000 kva, have been placed in service.

An even greater economic gain may be realized in the application of hydrogen cooling to high-speed turbine generators. With this class of machines, the windage and ventilation losses with air cooling comprise about half the full-load losses. Hence the use of hydrogen reduces the total losses by nearly half, corresponding to a gain of about 1 per cent in efficiency.

In one type of hydrogen-cooled turbine-generator, heat is extracted from the hydrogen in 4 surface coolers located within the generator housing and through which water is circulated. Because of the smaller losses and the improved performance of these coolers in hydrogen, their size is only about 40 per cent of that of the coolers of an air-cooled machine of equal rating. The volume of active material in such a machine is about 20 per cent less than would be required for an air-cooled machine of equal rating. To prevent the escape of hydrogen from the generator housing along the rotating shaft projections a sealing gland is provided in each bearing, which is supplied with vacuum-treated oil from a system operating in parallel with the bearing lubricating system.

In another type of hydrogen-cooled turbine-generator only the rotor is cooled with hydrogen, the stator being cooled by a number of hollow metal pads located between the core laminations and through which water is circulated. At the center of the core, pads with radial fins are provided, which serve both to remove the heat from the stator and to extract the losses from the hydrogen which has cooled the rotor. This type of installation requires the circulation of about 50 per cent less hydrogen than the other type, thus making possible the use of smaller fans and a shorter machine.

Commercial development of the hydrogen-cooled turbine-generator has just begun, but its importance to the industry is indicated by the fact that 17 machines of this type, with a combined output of nearly 850,000 kw, are now under construction. The yearly fuel saving for these 17 machines, as the result of using hydrogen cooling, is an item of some magnitude.

## Improvements in Distribution

After the power is generated, it must be delivered to the consumer with as little loss as possible, in suitable form as to constancy of voltage, and under suitable conditions as to continuity of service or availability. This is not a matter of just using large electrical conductors, but rather a scientific arrangement of interconnections of conductors, placement of transformers, protective and regulating devices, and a reduction of losses in trans-

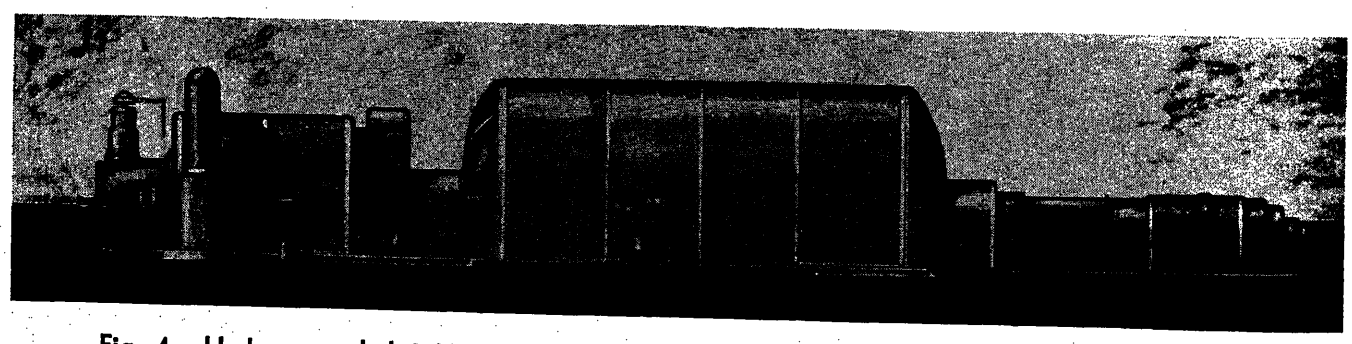

**Fig. 4. Hydrogen-cooled 3,600-rpm 40,000-kw generator driven by high-pressure high-temperature turbine, now being built for superposed installation in the Logan, W. Va., station of the American Gas and Electric Company**

**Turbine:** Pressure, 1,250 pounds per square inch; temperature 925 degrees Fahrenheit (red hot). Double-shell construction. Superposition of this unit will add 86 per cent to station capacity but with only a moderate increase in fuel consumption

**Generator:** Windage losses reduced (by use of hydrogen) to 10 per cent of what these losses would be if the machine were operated in air. Water-cooled stator. Aluminum field winding. Full load losses 1.4 per cent; full load efficiency 98.6 per cent

formers and regulating devices. The average distribution losses of the power systems of the United States in 1920 were 21½ per cent; in 1936 this had been reduced to 15 per cent.

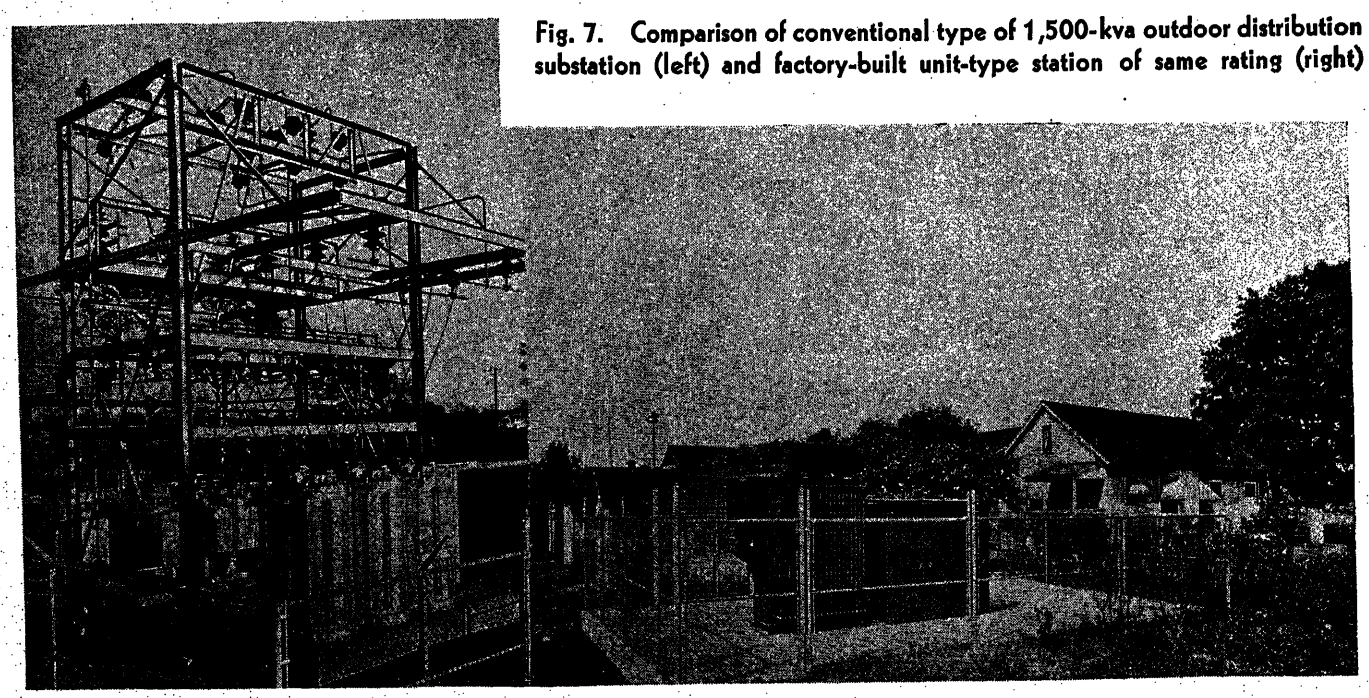
The marked and continuing improvement of transformer efficiency has played an important part in reducing the distribution losses. Since 1920 the losses of distribution transformers have been reduced an average of 20 per cent. The average full-load losses of power transformers have been reduced 45 per cent, while the core losses have been reduced 62½ per cent over the same period. Figure 6 illustrates the rapid advance in the design of network transformers.

## Improvements in Power Cable

Paralleling the improvement in transformers, it is interesting to note the progress made in paper-insulated cable since 1920. Previous to 1921 the highest voltage underground cable in use in the United States was 3-conductor 26-kv Y-grounded cable. In 1921, the first 3-conductor 33-kv cable in the United States was installed, but trouble developed and the operating voltage had to be reduced to 22 kv. In 1923 the first 66-kv single-conductor solid-type paper-insulated cable in the United States was installed, and in 1927 *the first* commercial installation in the world of 132-kv oil-filled cable

**Fig. 6. Comparison of 1928, 1932, and 1936 network distribution transformers**

| | 1928 | 1932 | 1936 |
|---|---|---|---|
| Approximate vault space required (feet) | 17 by 4.5 by 9 deep | 14 by 4.5 by 8 deep | 11 by 4 by 6 deep |
| | 100% | 56.5% | 29.7% |
| Efficiency | 98.5% | 98.7% | 98.7% |
| Weight (oil-filled) | 100% | 82.5% | 82.5% |



was put into service in the United States. Approximately 900 miles of oil-filled cable is now in service, and there has not been a single electrical failure in this cable in the United States. There is an installation of 230-kv oil-filled cable abroad but none operating at this voltage in this country, although manufacturers are prepared to supply it. Laboratory and field tests have been carried on for several years to determine if 230-kv oil-filled cable is feasible, and these tests are favorable.

Progress in the development and application of high-voltage paper-insulated cable has been made possible by improved materials and better manufacturing methods, and also by the development of the oil-filled cable. Thoroughly washed wood-pulp paper has taken the place of the oiled manila paper, and fluid oils have taken the place of the old petrolatum compounds. Low ionization has resulted from much better vacuum equipment and the complete filling of the cable with insulating oil; dielectric losses have been greatly decreased by the improvements in the paper and the oil. Dielectric losses at operating temperatures have been greatly reduced since 1925. This reduction in losses in the solid type of cable has been approximately 60 per cent, and in the oil-filled cable since 1927 approximately 40 per cent.

Another advance in distribution equipment is illustrated in figure 7.

Direct-current power transmission is very attractive from many points of view. It offers the possibility of operating cables with negligible dielectric losses at greatly increased voltages with consequent reduction in cable cost, and also a means of obtaining nonsynchronous ties between power stations. The General Electric Company has a developmental installation, but at present this is regarded as just another laboratory step which ultimately may come into commercial use and still further reduce transmission losses.

**Fig. 7. Comparison of conventional type of 1,500-kva outdoor distribution substation (left) and factory-built unit-type station of same rating (right)**

## Improvements in Electric Appliances

After the power has reached the consumer, it should be used efficiently in his appliances. As examples, improvements in 2 appliances will be cited—the incandescent lamp and the household refrigerator.

More than 880,000,000 incandescent lamps were manufactured in 1936. For each kilowatt-hour the users of these lamps will receive $^1/_3$ more light than they did from lamps of the same wattage in 1920, and each lamp will cost $^2/_3$ less than in 1920.

At no time in the past has there been more activity in lighting research than at present. Illumination studies are under way on a more extensive scale than ever before, and illuminating engineers have many new types of lamps to experiment with—the sodium lamp, the high-intensity mercury-vapor lamp, and fluorescent lamps, all subject to further development.

There are in service now approximately 7,000,000 household electric refrigerators. Today, 3 electric refrigerators operate with the same electric-power consumption as one required in 1926, and the user may purchase a much superior unit for less than half the amount he paid in 1926. Great advances have been made in styling or in improving the appearance of refrigerators and all household devices. This is illustrated in figure 8.

This improvement has been a matter of putting into these devices the same research, high technical ability, and ingenuity as has been applied to larger apparatus.

| Installed price (approximate) | $310 | $200 |
| Capacity, Btu per hour | 340 | 530 |
| Economy, watt-hours per Btu | 450 | 340 |
| Ice-freezing rate, pounds per hour | 0.66 | 2.04 |
| Average kilowatt-hours per month | 55 | 28 |
| Pounds weight per Btu (unit only) | 0.662 | 0.258 |

**Fig. 9. Consumption of electricity in domestic service and average cost per kilowatt-hour, since 1913**

Similar advances have been made in electric ranges and water heaters, washing machines and ironers, radios, food mixers, toasters, and heating appliances.

Air conditioning is getting under way and will be greatly extended. One of the big problems in air conditioning is the quiet and efficient movement of air; this has stimulated fan research, the results of which already have effected remarkable improvements.

A new household servant has appeared in the disposal unit which macerates waste food from the kitchen, and discharges it into the sewage system. Some day, perhaps, this will be as compulsory as the sewage system itself is today.

The result of all this is shown in figure 9, which depicts how the power companies have taken advantage of these engineering achievements in power generation and transmission and distribution, and have passed them along to the user in the way of lower and lower rates so that the average rate to the domestic consumer today is but little more than half what it was in 1916. The consumer has taken advantage of the lower rates, and of the new and improved lamps and devices, and has increased the average domestic use from 260 kilowatt-hours per year to 709, or more than double. Furthermore the service has improved as to reliability, continuity, and constancy of voltage. What does the consumer pay for this service? If he uses the average 700 kilowatt-hours per year and pays the average rate, he pays just one week's wages for the average American workingman. What else can he purchase that does so much for him—a whole year's electric service for one week's pay? He can buy an electric refrigerator for one month's pay, a better refrigerator than the working man in Europe can buy for 3 months' pay.

In conclusion, then, it may be said that the research and engineering objective of power engineers is to obtain more and more electric power from each unit of fuel, to lose less and less of that power in distributing it to the user, and to have each unit of power do more and more for the user, all to the end that the maximum benefits may be obtained from our natural resources to the best social and economic interest of the nation.

# Employment in the Engineering Profession

**Between 1930 and 1934 there was a substantial net loss of employment among those engineers in the United States who entered the profession before 1930, and a considerable absorption in employment of newcomers to the profession. This is one important conclusion reached by the Bureau of Labor Statistics of the United States Department of Labor after analyzing reports from 52,589 professional engineers obtained in the 1935 survey of the engineering profession conducted by the Bureau at the request and with the co-operation of American Engineering Council. This article,* third in the series reporting the results of this survey, presents data pertaining to the employment of engineers during 1929–34.**

ANALYSIS has been made by the Bureau of Labor Statistics, United States Department of Labor, of reports from 52,589 professional engineers, showing the kinds of employment engaged in at specified periods. The study was undertaken in May 1935, at the request of the American Engineering Council. The following general findings were established by this analysis:

Over the 5-year period ending December 1934, the number of persons in the engineering profession increased by 25.3 per cent. This rate of increase was much in excess of available engineering employment opportunities. The growth among the several professional classes over the period 1930–34 ranged from 17.6 per cent for mining and metallurgical to 62.5 per cent for chemical and ceramic engineers.

The lack of opportunities for engineering employment differed markedly among the professional classes. Thus, over the 5-year period, and for the profession as a whole, private engineering employment declined by 8.2 per cent, but it increased by more than a third for chemical and ceramic engineers. There was little increase or decrease for electrical, mining and metallurgical, and mechanical and industrial engineers. In the case of the civil engineers, however, there was a decrease of about $^1/_8$ in private engineering employment.

All professional classes participated in the increases in employment of engineers by public authorities. The civil engineers were most affected. The proportion of this group employed by public authorities increased from 40.0 per cent in 1929 to 48.5 in 1934.

The fact that available engineering opportunities did not keep pace with the increase in the number of men trained to enter the profession brought about changes in the proportions of those who were unemployed or engaged in nonengineering work.

In 1929 private engineering furnished by far the greatest employment for engineers. For civil engineers this covered 54.3 per cent. There was a range of from 80.6 to 87.3 per cent among the 4 remaining professional classes. By December 1932 private engineering among civil engineers had dropped to 37.6 per cent, and by December 1934 to 31.8 per cent. There was also a continuous decline in this type of employment among electrical engineers; only 63.1 per cent reporting such employment in December 1934. There was only a slight improvement over 1932 for the remaining professional classes. In 1934 these 3 averaged 69.1 per cent.

Nonengineering employment increased sharply from 1929 to 1932 and in equal measure for all professional classes, absorbing many more engineers than did public engineering, in which employment also increased. But despite the fact that the proportions of all engineers in nonengineering employment rose from 6.3 per cent in 1929 to 12.0 per cent in 1932, there was an even larger increase in unemployment. This situation was common to all professional classes.

Between December 1932 and December 1934 there were further increases in nonengineering employment for all professional classes. The increases were not so great as between 1929 and 1932. Unemployment declined for all professional classes, except for civil engineers.

The sharpest increases in public-engineering employment occurred in the period 1932–34.

Of all engineers who reported being professionally active prior to 1930, only 46.2 per cent were in the employ of private firms in 1934; in 1929, 62.2 per cent were so engaged. Federal government employment provided for 10.1 per cent in December 1934; in 1929, this field gave employment to only 5.3 per cent.

Over the period 1930–34 there was a remarkable stability in the number of engineers classified as independent consultants, and those engineers engaged in the teaching of engineering subjects. This was also true of those in the employ of state and county, and municipal and other public authorities, especially if considered together.

The net new private-firm employment that developed between 1930 and 1934 was secured by newcomers who entered the profession in this period. In absolute number, 5,003, or 16 per cent, of the engineers active in the profession before 1930 suffered loss of engineering employment. Some 3,112, or 18 per cent, of the new entrants found engineering work with private firms. The increase in public engineering employment was shared by both older and younger engineers.

## Scope and Method of Study

The primary objectives of this analysis were to determine what kinds of engineering employment were most stable, and what types of substitute employment pro-

* An article prepared by Andrew Fraser, Jr. of the Division of Hours, Wages, and Working Conditions, Bureau of Labor Statistics, United States Department of Labor, which article was published in the April 1937 issue of *Monthly Labor Review*. Articles reporting other phases of this survey were published in ELECTRICAL ENGINEERING as follows: "Professional Aspects of Engineering Education," August 1936, pages 863–7; "Unemployment in the Engineering Profession," February 1937, pages 216–23. A detailed report of the survey will be published later in bulletin form by the Bureau of Labor Statistics.

## Table I—Distribution of All Professional Engineers by Employment Status Reported at End of 1929, 1932, and 1934

(Figures adjusted as explained on page 525)

| Employment Status | Number | | | Per Cent | | | Increase or Decrease in Number | | |
|---|---|---|---|---|---|---|---|---|---|
| | 1929 | 1932 | 1934 | 1929 | 1932 | 1934 | 1929 to 1932 | 1932 to 1934 | 1929 to 1934 |
| Grand total, United States | 31,252 | 35,691 | 39,161 | 100.0 | 100.0 | 100.0 | +4,439 | +3,470 | +7,909 |
| Engineering employment | 29,051 | 27,787 | 30,299 | 93.0 | 77.9 | 77.4 | −1,264 | +2,512 | +1,248 |
| Private[a] | 22,456 | 19,797 | 20,619 | 71.9 | 55.5 | 52.7 | −2,659 | + 822 | −1,837 |
| Public[b] | 6,595 | 7,990 | 9,680 | 21.1 | 22.4 | 24.7 | +1,395 | +1,690 | +3,085 |
| Nonengineering employment | 1,969 | 4,290 | 5,523 | 6.3 | 12.0 | 14.1 | +2,321 | +1,233 | +3,554 |
| Unemployment | 232 | 3,614 | 3,339 | 0.7 | 10.1 | 8.5 | +3,382 | − 275 | +3,107 |

*a.* Includes those engineers in the employ of private firms, independent consultants, reporting "any other employment," and teaching.
*b.* Includes those engineers in the employ of federal, state, county, municipal governments, and other public authority.

fessional engineers found during the depression years, 1930–34, inclusive.

The engineer was requested to check his employment status against only 1 of 14 items for each of the 3 years ending December 31, 1929, 1932, and 1934. In view of the small number reporting in some categories, similarity in the detailed distributions, and the desirability of discussing unemployment and related data as a whole, these 14 categories were reduced to 8 and are designated in this article thus: (1) private firm,[1] (2) independent consultant, (3) teaching, (4) Federal, (5) state and county, (6) municipal and other public authority, (7) nonengineering employment, (8) total unemployment.[2] In the ensuing discussion items 1 to 3 inclusive, and 4 to 6 inclusive are hereafter referred to, respectively, as private engineering employment and public engineering employment, and these 2 in combination as total engineering employment.

### Employment Status of Engineers, 1929–34

During the period 1930 to 1934, inclusive, the total number of engineers seeking employment was increased by almost 10,000 per year, largely through the addition of new college graduates. Thirty-two per cent of these recent college graduates reported to the bureau, in contrast to 15 per cent of those who were actively engaged in the profession prior to 1930. This disparity necessitated adjusting the sample to obtain the over-all distributions of employment status for 1932 and 1934, thus: The number of engineers graduating in 1930–34 and reporting employment status for 1932 and 1934 were reduced in the ratio of 15 to 32. These derived totals were then added to the remaining reports for 1932 and 1934. This was possible because for separate age groups among both the younger and older engineers the percentage of replies shows homogeneous sampling within these 2 groups. In determining the adequacy of these samples no allowances were made for deaths or severances from the profession occurring between December 1929 and December 1934.

These distributions for the years 1929, 1932, and 1934 are presented in table I for the profession as a whole.

Between December 1929 and December 1932 the total number of professional engineers in the sample increased by 4,439, from 31,252 to 35,691. There was a further increase of 3,470 to 39,161 by December 1934. The total increase from 1929 to 1934 amounted to 25.3 per cent.

This increase took place during 5 years of depression in which available engineering opportunities were insufficient to absorb the supply of engineers. For December 1932, 3,614 reported unemployment. The percentage of those reporting unemployment declined from 10.1 at the end of 1932 to 8.5 at the end of 1934. But in the face of the continuing influx of engineers, the absolute number of those unemployed declined only slightly to 3,339 at the end of 1934. Furthermore, while the presence of 6.3 per cent of the professional engineers in nonengineering employment in 1929 indicates this was even then an established and normal outlet for them, there was an enormous increase in such work between 1929 and 1932. There was a further, but smaller, increase in nonengineering work between 1932 and 1934. The number reporting themselves as engaged in such work increased from 1,969 in 1929 to 5,523 by December 1934. Among the engineers reporting, 12.0 and 14.1 per cent were engaged in nonengineering work in December 1932 and 1934, respectively. There is reason to believe, from a preliminary examination of income data, that the specific nonengineering work of many of those reporting in 1934 was much more frequently of a makeshift character than in 1929.

Engineering employment as a whole declined 4.4 per cent between 1929 and 1932. There was a rise by December 1934. The number in the adjusted sample engaged in engineering work increased from 29,051 in December 1929 to 30,299 in December 1934, but this was due primarily to the increases in the public employment of engineers. Private employment decreased by 11.8 per cent from 1929 to 1932. Despite some increase from 1932 to 1934, it was still 8.2 per cent below the 1929 level at the end of the 5-year period 1930–34.

The dependence upon public employment is further evidenced by the fact that although both classes of engineering employment increased between December 1932 and December 1934, the absolute increase reported in private employment was only half of that obtaining in employment with public authorities. Relative to the numbers so employed in 1932, the rate of increase in public employment was almost 5 times as great as that in private employment.

1. Includes also those reporting as employees of private consulting firms and under "any other employment" in question 6.

2. Includes also those reporting work relief and direct relief.

## Table II—Employment Status at End of 1929, 1932, and 1934 of All Engineers Reporting, by Professional Class

(Figures adjusted as explained on page 525)

| Professional Class | Number of Engineers | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Total | | | In Engineering Employment | | | | | | In Nonengineering Employment | | | Unemployed[c] | | |
| | | | | Total Private[a] | | | Total Public[b] | | | | | | | | |
| | 1929 | 1932 | 1934 | 1929 | 1932 | 1934 | 1929 | 1932 | 1934 | 1929 | 1932 | 1934 | 1929 | 1932 | 1934 |
| Total, United States | 31,252 | 35,691 | 39,161 | 22,456 | 19,797 | 20,619 | 6,595 | 7,990 | 9,680 | 1,969 | 4,290 | 5,523 | 232 | 3,614 | 3,339 |
| Chemical and ceramic | 1,470 | 1,931 | 2,389 | 1,217 | 1,322 | 1,640 | 103 | 122 | 143 | 143 | 320 | 459 | 7 | 167 | 147 |
| Civil, agricultural, and architectural | 13,786 | 15,330 | 16,365 | 7,477 | 5,760 | 5,191 | 5,510 | 6,620 | 7,941 | 694 | 1,413 | 1,556 | 105 | 1,537 | 1,677 |
| Electrical | 6,112 | 7,276 | 8,117 | 5,238 | 4,940 | 5,137 | 350 | 456 | 623 | 493 | 1,155 | 1,759 | 31 | 725 | 598 |
| Mechanical and industrial | 8,455 | 9,587 | 10,609 | 7,374 | 6,729 | 7,512 | 504 | 643 | 802 | 517 | 1,190 | 1,518 | 60 | 1,025 | 777 |
| Mining and metallurgical | 1,429 | 1,567 | 1,681 | 1,150 | 1,046 | 1,139 | 128 | 149 | 171 | 122 | 212 | 231 | 29 | 160 | 140 |

*a.* Includes employees of private firms, independent consultants, "any other employment," and teaching.
*b.* Includes federal state county, and municipal governments, and other public authority.
*c.* Includes direct relief and work relief.

The preceding analysis is concerned only with the engineering profession as a whole. Corresponding data for each professional class are presented on an adjusted basis in table II.

Over the 5-year period ending December 1934, the number of persons in the engineering profession increased by 25.3 per cent. The corresponding increases for the separate professional classes ranged from 17.6 per cent for mining and metallurgical engineers to 62.5 per cent for chemical and ceramic engineers (table III).

In no professional class did total engineering employment keep pace with the growing number of engineers. The closest balance between the increase in number of engineers and the increase in total engineering employment was 62.5 per cent to 35.1 per cent for chemical and ceramic engineers. That is, without displacement of such engineers in the profession in 1929 about half of their increase in number could have been absorbed in engineering work. The next highest increase in number, namely, 32.8 per cent, occurred among electrical engineers. This was met by an increase of only 3.1 per cent in their total engineering employment. Mechanical and industrial engineers fared somewhat better. Their numbers increased by 25.5 per cent, while opportunities for engineering employment increased by 5.5 per cent. Roughly, 1/6 of the total increase in number of all engineers between 1930 and 1934 was provided for by the growth of new jobs. Clearly, the wide variations in the rates of increase in these professional classes had an important bearing upon the nature of their employment distributions in the period 1929–34.

The data for private and public engineering in table III accentuate the differences in available engineering opportunities for each professional class. Thus, over the 5-year period, and for the profession as a whole, although private engineering employment declined by 8.2 per cent it increased by more than 1/3 for chemical and ceramic engineers. There was little increase or decrease for electrical, mining and metallurgical, and mechanical and industrial engineers; but for the civil engineers, there was a decrease of about 1/3 in private engineering employment.

By contrast, no professional class was excepted from the increases which took place in public engineering employment. It was the civil engineers, however, who were most affected. For them public employment was an important field in 1929 when 40 per cent of all civil engineers were so engaged. The 44.1 per cent increase by 1934 in the amount of such employment reported meant an absolute increase of 2,431 jobs over the 5-year period. In contrast, less then 6.0 per cent of electrical and mechanical engineers had been employed by public authorities in 1929. By December 1934, although the numbers of them so engaged had increased by 78 and 59.1 per cent, respectively, the absolute increases in jobs reported were only 273 for electrical and 298 for mechanical and industrial engineers. For chemical and ceramic, and mining and metallurgical engineers, the absolute increases were, respectively, 40 and 43.

Since the available engineering opportunities did not keep pace with the increases in men trained to enter the profession, there must obviously have been changes in the proportions, first, of those engaged in engineering and second, of those unemployed,[3] or engaged in nonengineering work. This is evidenced by considering the adjusted data presented in table IV.

## Table III—Per Cent of Change in Engineering Employment, by Professional Class, 1929 to 1934

(Figures adjusted as explained on page 525)

| Professional Class | Per Cent of Increase in Each Professional Class, 1929–34 | Per Cent of Increase or Decrease, 1929–34 in— | | |
|---|---|---|---|---|
| | | Total Engineering Employment | Private[a] Engineering Employment | Public[b] Engineering Employment |
| Total, United States | +25.3 | +4.4 | −8.2 | +46.8 |
| Mining and metallurgical | +17.6 | +2.5 | −1.0 | +33.6 |
| Civil, agricultural, and architectural | +18.7 | +1.1 | −30.6 | +44.1 |
| Mechanical and industrial | +25.5 | +5.5 | +1.9 | +59.1 |
| Electrical | +32.8 | +3.1 | −1.9 | +78.0 |
| Chemical and ceramic | +62.5 | +35.1 | +34.8 | +38.8 |

*a.* Includes employees of private firms, independent consultants, "any other employment," and teaching.
*b.* Includes employees of federal, state, county, and municipal governments and other public authority.

3. For detailed discussion, see "Unemployment in the Engineering Profession," ELECTRICAL ENGINEERING, February 1937, pages 216–23.

Private engineering employment furnished by far the greatest amount of employment to engineers. In 1929, even among civil engineers, 54.3 per cent were so employed. For the remaining 4 professional classes, the percentages ranged from 80.6 for mining and metallurgical to 87.3 for mechanical and industrial engineers. These proportions dropped sharply from 1929 to 1932 because of a decrease in the number of private jobs and an increase in the number of engineers. By December 1932, only 37.6 per cent of the civil engineers reported being in private engineering. The range for the remaining 4 professional classes was from 66.8 to 70.2 per cent. By the end of 1934, there was a further decrease in the proportions privately employed among both civil and electrical engineers. The former decreased to 31.8 per cent. Among electrical engineers, private engineering work had employed 67.8 per cent in 1932 as compared with 63.1 per cent in 1934. There was only a slight improvement over 1932 for the remaining professional classes.

In all classes, excepting chemical and ceramic engineers, the proportions engaged in public engineering increased from 1929 to 1934. The most pronounced shift occurred among the civil engineers, namely, from 40.0 per cent in 1929 to 48.5 per cent in 1934. This is some measure compensated for the large decline in the private engineering employment of this professional class. Indeed, as a result of public employment, the proportion of civil engineers in total engineering employment in both 1932 and 1934 was slightly higher than in any other professional class.

Lack of engineering employment opportunities in the period 1929–32 led to increases in both nonengineering employment and unemployment for all professional classes. In general, the loss of private employment occurred from 1929 to 1932. Nonengineering employment increased sharply, absorbing many more engineers than public engineering work, in which employment also increased. But despite the fact that the proportion of all engineers in nonengineering rose from 6.3 per cent in 1929 to 12.0 per cent in 1932, there was an even larger increase in unemployment. This situation was common to all professional classes.

There were further increases in the proportions engaged in nonengineering work among all professional classes in the period 1932–34. Among electrical engineers, the rate of increase in the proportion who were in nonengineering employment was $^3/_4$ of that which occurred in 1929–32. But for the remaining professional classes the corresponding rates of increase were only $^1/_3$ or less. In the case of civil engineers and mining and metallurgical engineers, there were almost no increases in the proportions engaged in nonengineering employment. For each of these groups there was a greater increase from 1932 to 1934 in public than in nonengineering employment. For civil engineers it was much larger. For mechanical engineers the proportions in public engineering rose from 6.7 per cent in 1932 to 7.6 per cent in 1934, whereas nonengineering embraced 12.4 per cent of all mechanical engineers in 1932 and 14.3 per cent in 1934. For mechanical engineers, therefore, the rate of expansion in public engineering employment was less than that which occurred in nonengineering employment.

## Employment Status in Comparable Age Groups

Comparison of the distribution of employment status in 1929 of all engineers who entered the profession in the period 1925–29, with that in 1934 of a comparable group who entered the profession between 1930 and 1934, reflects the pressures to which new entrants were subjected during the depression years. It also emphasizes the abnormality of the employment status of the latter in 1934.

In 1929 only 5.3 per cent of the most recent graduates with professional training were in nonengineering work and 0.4 per cent were unemployed. In other words, all but $^1/_{20}$ of those who entered the profession in these 5 years were employed in engineering work in 1929 (table V). But in 1934, $^2/_5$ of the comparable group of recent engineering graduates[4] were not in regular professional engineering work. No less than 10.6 per cent of them were unemployed in December 1934, while 29.4 per cent reported being engaged in nonengineering work.

Of all recent engineers, both in 1929 and in 1934,

4. The term "engineering graduate" is used interchangeably with "entered the profession." The tabulations cover predominantly those who received first degrees in engineering in the years specified, but also include all "other" engineers (such as those whose college work was incomplete) who were 23 to 27 years old at the date of reported employment.

**Table IV—Percentage Distribution of Engineers Reporting, by Employment Status and Professional Class, at End of 1929, 1932, and 1934**

(Figures adjusted as explained on page 525)

| Professional Class | Per Cent of Total in Each Professional Class Reporting— | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Engineering Employment | | | | | | Nonengineering Employment | | | Unemployment[c] | | |
| | Private[a] | | | Public[b] | | | | | | | | |
| | 1929 | 1932 | 1934 | 1929 | 1932 | 1934 | 1929 | 1932 | 1934 | 1929 | 1932 | 1934 |
| Total, United States | 71.9 | 55.5 | 52.7 | 21.1 | 22.4 | 24.7 | 6.3 | 12.0 | 14.1 | 0.7 | 10.1 | 8.5 |
| Chemical and ceramic | 82.8 | 68.5 | 68.7 | 7.0 | 6.3 | 5.9 | 9.7 | 16.6 | 19.2 | 0.5 | 8.6 | 6.2 |
| Civil, agricultural, and architectural | 54.3 | 37.6 | 31.8 | 40.0 | 43.2 | 48.5 | 5.0 | 9.2 | 9.5 | 0.7 | 10.0 | 10.2 |
| Electrical | 85.6 | 67.8 | 63.1 | 5.8 | 6.3 | 7.8 | 8.1 | 15.9 | 21.7 | 0.5 | 10.0 | 7.4 |

| Mining and metallurgical | 80.6 | 66.8 | 67.9 | 8.9 | 9.5 | 10.1 | 8.5 | 13.5 | 13.7 | 2.0 | 10.2 | 8.3 |

a. Includes employees of private firms, independent consultants, "any other employment," and teaching.
b. Includes employees of federal, state, county and municipal governments, and other public authority.
c. Includes direct relief and work relief.

approximately 1/6 were engaged in the 3 categories of public engineering. In so far as any differences existed, there appears to have been a slight decline in the proportions of the 1930–34 group that secured public employment. The decrease in the percentage in state and county employment was only from 8.8 to 7.5. But municipal and other public authorities in 1929 had employed 5.4 per cent of the 1925–29 engineers, whereas in 1934 they employed only 2.4 per cent of those who entered the profession in the period 1930–34. On the other hand, the federal government employed a larger percentage of the recent graduates in 1934 than it had in 1929. For 1929, 6.5 per cent of the 1925–29 engineers reported themselves as having been employed by the federal government, whereas 9.2 per cent of the recent entrants to the profession were so employed in 1934.

In 1929 nearly 3/4 of the recent engineers were in private engineering employment. Only 40.9 per cent of the 1930–34 engineers so reported for December 1934. Clearly, the abnormally large proportion of the new entrants to the profession who were unemployed or were compelled to find work of a nonengineering nature in 1934 was due primarily to the lack of opportunities in the principal field of engineering activity. A contributory factor of substantial importance, however, was that the number of those graduated from engineering courses in colleges was about 20 per cent higher from 1930 to 1934 than from 1925 to 1929. In number, this increase was about 10,000 individuals.

This dependence upon private engineering employment is common to the greater part of the engineering profession. A substantial number, however, is normally in the employ of public authorities. This is borne out by considering the distributions of employment status of all engineers reporting. These data are shown in table VI, divided into 3 broad classes, by age.[5]

Of all older engineers reporting for December 1929, it may be noted that 71.9 per cent were engaged in private engineering, 21.1 per cent in public engineering, 6.3 per cent in nonengineering work and only 0.7 per cent were unemployed. Of the 71.9 per cent in private engineering, 62.2 per cent were in the employ of private firms, 4.2 per cent in independent consulting work, and 5.5 per cent in teaching. In public engineering, the percentages for federal, state, and county, and municipal and other public authorities ranged from 5.3 to 7.4. This situation had an important bearing on the changes which occurred in the subsequent period, especially with regard to substitute employment.

Over the 5-year period there was a net change in the distributions of employment affecting 16.8 per cent of the "older" engineers; that is, of engineers who had entered the profession prior to 1930. In other words, out of every 1,000 engineers reporting, there were net changes in the employment status of 168 between 1929 and 1934. In absolute numbers, there were shrinkages of 5,255 jobs for engineers graduating prior to 1929. No less than 5,002 were separated from private firms. The remaining net losses of employment were distributed among those engaged in independent consulting (60), in teaching (16), and in municipal and other public employment (177). These decreases in employment opportunities for older engineers were not counterbalanced by increases in the other classes of engineering employment. In fact, 2,270 engineers reporting graduation prior to 1930 were still unemployed in December 1934, while 1,233 found employment in nonengineering work. Only 1,752 had been absorbed by increases in public engineering employment, 1/6 with state and county authorities, and 5/6, or 1,502, with the federal government.

The major part of the loss of employment for older engineers occurred from 1929 to 1932. In this period net shifts in employment had affected the status of 14.7 per cent of these men. The net change in the period 1932–34 involved only 4.0 per cent of them. Obviously, by December 1932 the engineering profession had suffered the major impact of the depression. Between December 1929 and December 1932 there were net losses of employment involving 4,608 engineers. Only 2 of the categories of employment were involved, namely, that with private firms, and that with municipal and other public authorities. But of the 4,608 positions concerned, the shrinkage of employment with private firms affected 4,530; the latter, only 78. Of these engineers, only 884 were able to find other types of engineering employment by December 1932; nearly 50.0 per cent of them entered federal-government employment, while 1/3 entered state and

5. Table VI presents the absolute figures for all reports received without adjustment. It deals with the older and younger engineers separately and, therefore, no adjustment was required in these broad age classifications, though allowance did have to be made for the relatively large number of reports received from young engineers when the groups were treated in combination.

Older engineers comprise all those who were active in professional engineering prior to 1930. The younger engineers are those who entered the profession in the years 1930–34, inclusive, and are divided into 2 broad age groups, each designated by the graduating classes which they embrace, namely, 1930–32 engineers and 1933–34 engineers. Furthermore, in tabulating the data on employment status, homogeneity of the older and 1930–32 engineers was maintained. That is, in the case of the former, only those reporting for the 3 years 1929, 1932, and 1934 were used; in the case of the latter, only those reporting for the 2 years 1932 and 1934 were included. Analysis shows that the percentage eliminated was small.

**Table V—Comparative Employment Status of 2 Groups of Younger Engineers**

| Age Group | Total | In Private[a] Engineering Employment | In Public Engineering Employment: Federal | State and County | Municipal and Other Public Authority | In Nonengineering Employment | Unemployed[b] |
|---|---|---|---|---|---|---|---|
| | Number of Engineers | | | | | | |
| 1925–29 engineers, who were 23 to 27 years of age in 1929 | 6,997 | 5,151 | 452 | 618 | 375 | 371 | 30 |
| 1930–34 engineers, who were 23 to 27 years of age in 1934 | 16,872 | 6,910 | 1,544 | 1,272 | 401 | 4,959 | 1,786 |
| | Per Cent | | | | | | |
| 1925–29 engineers, who were 23 to 27 years of age in 1929 | 100.0 | 73.6 | 6.5 | 8.8 | 5.4 | 5.3 | 0.4 |
| 1930–34 engineers, who were 23 to 27 years of age in 1934 | 100.0 | 40.9 | 9.2 | 7.5 | 2.4 | 29.4 | 10.6 |

*a.* Includes employees of private firms, independent consultants, "any other employment," and teaching.
*b.* Includes work relief and direct relief.

## Table VI—Distribution of Older and Younger Engineers Reporting, by Employment Status, at End of 1929, 1932, and 1934

| Employment Status | Number | | | | | | Per Cent | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Older Engineers[a] | | | Younger Engineers | | | Older Engineers[a] | | | Younger Engineers | | |
| | | | | 1930–1932[b] | | 1933–1934[c] | | | | 1930–1932[b] | | 1933–1934[c] |
| | 1929 | 1932 | 1934 | 1932 | 1934 | 1934 | 1929 | 1932 | 1934 | 1932 | 1934 | 1934 |
| Grand total, United States | 31,252 | 31,252 | 31,252 | 9,469 | 9,469 | 7,403 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Engineering employment | 29,051 | 25,327 | 25,548 | 5,248 | 6,057 | 4,070 | 93.0 | 81.1 | 81.8 | 55.4 | 64.0 | 55.0 |
| Private employment | 22,456 | 18,142 | 17,378 | 3,532 | 3,926 | 2,984 | 71.9 | 58.1 | 55.7 | 37.3 | 41.5 | 40.4 |
| Private firm | 19,424 | 14,894 | 14,422 | 3,247 | 3,748 | 2,892 | 62.2 | 47.7 | 46.2 | 34.3 | 39.6 | 39.2 |
| Independent consultant | 1,303 | 1,459 | 1,243 | 50 | 25 | 17 | 4.2 | 4.7 | 4.0 | 0.5 | 0.3 | 0.2 |
| Teaching | 1,729 | 1,789 | 1,713 | 235 | 153 | 75 | 5.7 | 5.5 | 5.5 | 2.5 | 1.6 | 1.0 |
| Public employment | 6,595 | 7,185 | 8,170 | 1,716 | 2,131 | 1,086 | 21.1 | 23.0 | 26.1 | 18.1 | 22.5 | 14.6 |
| Federal | 1,647 | 2,063 | 3,149 | 531 | 1,008 | 536 | 5.3 | 6.6 | 10.1 | 5.6 | 10.6 | 7.2 |
| State and county | 2,632 | 2,884 | 2,882 | 927 | 872 | 400 | 8.4 | 9.2 | 9.2 | 9.8 | 9.2 | 5.4 |
| Municipal and other public authority | 2,316 | 2,238 | 2,139 | 258 | 251 | 150 | 7.4 | 7.2 | 6.8 | 2.7 | 2.7 | 2.0 |
| Nonengineering employment | 1,969 | 3,047 | 3,202 | 2,651 | 2,655 | 2,304 | 6.3 | 9.7 | 10.2 | 28.0 | 28.0 | 31.1 |
| Unemployment | 232 | 2,878 | 2,502 | 1,570 | 757 | 1,029 | 0.7 | 9.2 | 8.0 | 16.6 | 8.0 | 13.9 |

a. Includes both graduates and "other" engineers who were professionally active prior to 1930.
b. Includes both graduates and "other" engineers who entered the profession in the years 1930–32.
c. Includes both graduates and "other" engineers who entered the profession in the years 1933 and 1934.

county employment. There were 156 additional engineers reporting themselves as being independent consultants and 60 as engaged in teaching. Of the remaining 3,724 engineers, 2,646 were unemployed and 1,078 were engaged in work of a nonengineering nature.

The shifts noted in the period 1929–32, therefore, are indicative of 2 trends affecting engineers who had been in the profession in 1929: (1) the pronounced increase in federal employment and the decrease in private employment; and (2) the comparative stability of the remaining classes of engineering employment. These trends are accentuated further by a consideration of the shifts which occurred between December 1932 and December 1934.

In 1932–34, all categories of engineering employment, with the exception of that with federal government, decreased. Thus, an additional net total of 472 engineers graduating before 1930 were separated from private firms. The decreases in jobs in the remaining engineering classes ranged from 2 in the case of teaching to 216 for independent consultants. Incidentally, it may be noted that the proportion engaged in the latter class was only slightly less than the proportion so engaged in 1929. This would seem to indicate that the increase which did take place by December 1932 was an artificial one. Altogether, the decreases in engineering employment affected 865 engineers. Despite these decreases in many types of job opportunity, there was also a decrease of 376 in the number of engineers reporting unemployment. Only 155 found opportunities in nonengineering employment. The federal government gave engineering employment to the remaining 1,086 (87.5 per cent) of those whose status shifted from 1932 to 1934.

The net result of the changes in employment status among the older engineers was such that by December 1934 only 46.2 per cent were in the employ of private firms, whereas 62.2 per cent had been so engaged at the end of 1929. Federal employment provided for 10.1 per cent in December 1934, as against only 5.3 per cent in 1929. All other classes of engineering employment remained comparatively stable over the period 1930–34, especially if state, county, and municipal employment are considered together. In December 1934 there were 8.0 per cent unemployed, but it is obvious that had not 10.2 per cent of the older engineers found work of a nonengineering nature, the proportion unemployed would have been larger by that amount. It is also obvious that by December 1934 it was primarily the increased engineering employment by the federal government that ameliorated employment conditions for these older engineers.

Among the engineers who entered the profession during the depression, certain outstanding shifts may be noted. In the first place employment opportunities increased from the end of 1932 to the end of 1934 among those who graduated in 1930–32. Slightly more than half the 16.6 per cent of this group who had been unemployed or on work relief in 1932 found employment by 1934. Furthermore, they had found nonrelief engineering employment. There was no change in the proportion engaged in nonengineering work. The gain was almost equally divided between private employment and public employment. Fewer engineers were teaching or engaged in consulting work. The increase in employment by private firms, however, absorbed 5.3 per cent of all engineers in these classes. Similarly, there was a slight decline in the proportions employed by states and counties, but this was much more than offset by an expansion of federal engineering employment that absorbed an additional 5.0 per cent of the total number.

A comparison of the distributions of employment of 1933–34 graduates in 1934 may be made with employment in 1932 of those graduating in 1930–32 to show how conditions had changed as regards the most recent graduates. This comparison is not perfect because in the one case 3 graduating classes are considered and in the other only 2.

From 1932 to 1934 there was almost no change in the proportions of the most recent graduates who found engineering employment. Unemployment was slightly lower, primarily because 3.1 per cent more 1933–34 graduates

were in nonengineering work in 1934 than had been true of 1930–32 graduates in 1932.

While recent graduates in 1934 had as much opportunity for engineering employment as a comparable group had had in 1932, this was because of an expansion in private employment and particularly employment with private firms. In 1934, 4.9 per cent more of the 1933–34 graduates were employed by private firms and 1.8 per cent fewer were in teaching or acting as independent consultants than had been the case in 1932 among 1930–32 graduates.

The total opportunities for public employment were less in 1934 among the most recent graduates than had been true of a similar group in 1932. The federal government did employ 1.6 per cent more of them in 1934, but this could not offset the decline of employment opportunities with states, counties, and municipal authorities from 12.5 per cent of the 1930–32 graduates in 1932 to 7.4 per cent of the 1933–34 graduates in 1934.

The preceding discussion has shown the barriers that the depression threw in the way of newcomers to the profession. It now remains to examine the effect that even the partial absorption of the newcomers had upon the employment opportunities of the older engineers.

This interrelationship is best studied in 2 different phases of the employment cycle: (1) during a period of an absolute contraction in job opportunities, and (2) during a period of expansion. These conditions are represented, respectively, by the 2 periods 1929–32 and 1932–34. In the first, it may be recalled that total engineering employment for the adjusted sample decreased from 29,051 to 27,787. In the second period, it grew to 30,299 by the end of 1934. The adjusted data are presented in table VII.

By December 1932 employment with private firms had declined by 15.5 per cent. The loss of employment by private firms among older engineers was even greater than this. In absolute numbers, 4,530 were put out of work. Despite the enormous drop, even at this period of the depression no less than 1,522 of those engineers who entered the profession in the period 1930–32 found opportunities for engineering employment with private companies. Thus, approximately $^2/_3$ of the loss of employment among older engineers was due to a decrease in the total amount of private employment available; $^1/_3$ of it was due to the fact that older engineers were unable or unwilling to take employment which newcomers to the profession secured.

By the end of the second period, private-firm employment increased by 1,118 or 6.8 per cent, over that reported for December 1932. Here again there was a repetition of the condition noted for the period 1929–32. Even in this period there was a reduction in employment with private companies, affecting 472 of the older engineers. In passing, it should be noted that this decrease did not affect those who entered the profession from 1925 to 1929, but was confined to those who graduated prior to 1925. Essentially, therefore, those who entered the profession in the years 1930–34 secured all the net new employment that developed with private firms and also continued to find some openings at the expense of older engineers. Over the entire 5-year period 1930–34, although 5,002 older engineers suffered loss of employment with private firms, no less than 3,112 of the new entrants found engineering work.

A considerable number of the younger engineers were able to enter engineering activity with private firms, apparently at the expense of the older engineers. But this was probably not the result of a direct displacement on a particular job of any one group of older by younger engineers. The explanation is to be found in the relative ease with which a younger engineer found a new job as compared with an older one who had lost a job. The older engineer inevitably had a greater concern with the suitability of the employment and remuneration offered than had the man without an established position. Furthermore, the enormous influx of new entrants to the profession caused keen competition for all kinds of engineering employment, which, under the then prevailing conditions, were very definitely not of the type to suit the older engineers and which further depressed salary rates for the more elementary types of work.

The changes effected by the depression upon the engineers in the employ of state and county, and municipal and other public authorities, are in striking contrast to those which occurred among older engineers in private firms. Between 1929 and 1932 there was a 14.7 per cent increase over the total of 4,948 who were engaged by state and county and municipal and other public authorities in 1929. The increase was shared by both the older engineers and new entrants. The number of the former increased by 174, the latter by 555. By December 1934 the total so employed had increased to 5,804. But in this second period only the new entrants increased—by 228—whereas the older engineers decreased by 101, a net change in favor of the younger engineers of 127. It may be noted, however, that 73 of the net number of older engineers who entered these fields of employment by December 1932 were retained.

Clearly, the older engineers in the employ of these particular public authorities held on to their jobs tenaciously

**Table VII—Increases or Decreases in Employment of Older Engineers and Younger Engineers, by Class of Employment, 1929 to 1934**

(Figures adjusted as explained on page 525)

| Employment Class | Total Number Reporting | | | Increase or Decrease | | | |
|---|---|---|---|---|---|---|---|
| | | | | 1929 to 1932 | | 1932 to 1934 | |
| | 1929 | 1932 | 1934 | Older[a] Engineers | New[b] Entrants | Older[a] Engineers | New[c] Entrants |
| All classes | 27,988 | 28,694 | 32,735 | −2,862 | +3,568 | +668 | +3,373 |
| Private firm | 19,424 | 16,416 | 17,534 | −4,530 | +1,522 | −472 | +1,590 |
| State, county, and municipal government and other public authority | 4,948 | 5,677 | 5,804 | +174 | +555 | −101 | +228 |
| Federal government | 1,647 | 2,312 | 3,872 | +416 | +249 | +1,086 | +474 |
| Nonengineering | 1,969 | 4,289 | 5,525 | +1,078 | +1,242 | +155 | +1,081 |

a. Includes all engineers who were professionally active prior to 1930.
b. Includes all engineers who entered the profession in the years 1930 to 1932 inclusive.
c. Includes all engineers who entered the profession in the years 1933 and 1934, and also came in during this period from classes of 1930–32.

during the depression. The most marked shift as regards this type of employment was the decrease in the proportion of younger engineers who found work with such authorities. The decrease in the number of older engineers so employed by December 1934 may not have been due wholly to the increase of new entrants. Many of the older engineers may have found this employment an easier passage to federal employment, which, in the period 1932–34, required a large number of engineers as administrators and supervisors for the work-relief programs then under way. These positions may have been more in keeping with the older engineers' previous training and experience.

This last statement is substantiated by the changes which occurred in federal employment. In both periods the absolute number of older engineers who found this kind of work was greater than that for younger engineers. Thus, by the end of December 1932, federal employment increased 40.0 per cent from 1,647 to 2,312. This increase covered 665 engineers, which comprised 62.5 per cent older and only 37.5 per cent younger engineers. In the second period, the total number in the employ of the federal government increased from 2,312 to 3,872, an increase over 1932 of 68.0 per cent. The absolute increase was divided in the ratio of 70.0 per cent of the older to 30.0 per cent of the younger engineers. Over the 5-year period, the respective total absolute increases were 1,502 and 723. It was also be noted that, while in the period 1929–32 the rate of increase of older to younger engineers was 2 to 1, it increased $2^1/_2$ times for the older by the end of December 1934. From this marked preference for older engineers in federal government employment, it can only be assumed that the nature of the work did more closely meet their criteria for re-employment, at least for such opportunities as were available.

Over the 5-year period the younger engineers also had a decided advantage in securing nonengineering employment. Thus, while 1,233 older engineers were so engaged, 2,323 of the younger were able to find work of a nonengineering nature. This is made clear from an analysis of age groups of the relative increase in the number of those engaged in nonengineering to the total number displaced from engineering. The ratio of those who secured nonengineering work decreased progressively with age. Thus, 15 per cent of the displaced engineers who were over 52 years old in 1934 secured nonengineering work. The remainder were unemployed. Among those who were 28 to 32 years of age, 52 per cent secured nonengineering employment. But even the ratio of 52 for engineers entering the profession in 1925–29 was very much less than either of those for the 1930–32 and the 1933–34 engineers; for the former this was 78 and for the latter 69.

This analysis indicates that, taking all factors into consideration, between 1930 and 1934 there was a substantial net loss of employment by the engineers active before 1930, and a considerable absorption in employment of newcomers to the profession. Some of this shift may have been due to direct displacement; some of it to the securing of newly created positions by the younger men. There is no evidence bearing on the proportions affected by these 2 tendencies.

# Unemployment as of February 1937

## Reported by National Industrial Conference Board

THE TOTAL number of unemployed workers in February 1937 was 8,914,000, according to estimates of the National Industrial Conference Board made public April 19, 1937. This is a decrease of 203,000 (2.2 per cent) from the revised estimate for January 1937 and a decrease of 1,865,000 (17.3 per cent) from February 1936.

Employment in all types of enterprise in the United States in February 1937 as reported was 43,881,000 workers, an increase of 252,000 workers (0.6 per cent) over January 1937 and 2,457,000 (5.9 per cent) over February 1936. The number of workers employed in February 1937 was reported as 3,395,000 (7.2 per cent) below the average of 47,276,000 workers employed in 1929.

From January 1937 to February 1937 the increases reported in employment, by industrial groups, were: manufacturing, 233,000; service, 49,000; transportation, 29,000; construction, 20,000; trade, distribution and finance, 17,000; mining, 6,000; and public utilities, 1,000. The only decrease, amounting to 113,000, was found in agriculture.

Compared with February 1936, according to the report, employment in February 1937 increased 13.4 per cent in manufacturing; 7.7 per cent in trade, distribution and finance; 7.5 per cent in transportation; 5.7 per cent in the public utilities; 5.4 per cent in mining; 5.2 per cent in the service industries; 1.7 per cent in forestry and fishing; and 0.9 per cent in agriculture. The only decrease, amounting to 13.2 per cent, was found in construction.

The accompanying table prepared by the Conference Board shows the number of employed workers in the various industrial groups in 1929, February 1936, January 1937, and February 1937.

### Number of Employed Workers (in Thousands) Reported by National Industrial Conference Board

| Group Division | 1929 Average | February* 1936 | January* 1937 | February** 1937 |
|---|---|---|---|---|
| Agriculture | 10,650 | 10,335 | 10,542 | 10,429 |
| Forestry and fishing | 268 | 172 | 175 | 175 |
| Industry | | | | |
| Mining | 1,087 | 725 | 758 | 764 |
| Manufacturing | 11,073 | 9,518 | 10,565 | 10,798 |
| Construction, public and private | 2,841 | 1,387 | 1,184 | 1,204 |
| Transportation | 2,416 | 1,754 | 1,857 | 1,886 |
| Public utilities | 1,167 | 888 | 938 | 939 |
| Trade, distribution and finance | 7,323 | 6,751 | 7,251 | 7,268 |
| Service industries | 9,070 | 8,620 | 9,016 | 9,065 |
| Misc. industries and services | 1,381 | 1,273 | 1,345 | 1,352 |
| Total employed | 47,276 | 41,424 | 43,629 | 43,881 |

# Police Radio Communication

By EDWIN LEE WHITE  E. C. DENSTAEDT

## Synopsis

The history and development of police radiocommunication is discussed and an outline given of the federal regulations under which this type of service is rendered together with reasons therefor. The problems arising in the selection of equipment and during the installation and operation of police radio systems are discussed. The methods of operation of the various classes of police radio services are described. The various uses of radio covered by this paper are:

1. By municipalities for one-way communication to mobile units and remote police stations
2. By municipalities for 2-way communication with mobile units
3. By states in the general dispatching of state police units
4. By states and municipalities for the ratiotelegraphic exchange of police information
5. By harbor police in connection with the dispatching of harbor police boats and general policing of shipping
6. By states for emergency radiotelegraphic use in the event of interruption of the wire teletype network

Illinois state police radio station, Chicago

## History and Regulation

A GENERAL study of the history of police communication systems indicates that the police of the United States have always been progressive in adapting new communication facilities to police uses. As new systems were developed they were pressed into police service to assist in the never-ending battle with crime. We thus find the wire telegraph used by New York City Police Department in 1847. In 1878 just 2 years after its invention by Dr. Bell, the Chicago Police Department installed a police telephone system. Emergency police dispatching systems with telephones for communication were in use before the automobile had replaced the bicycle and horse as a means of transportation.

Probably the first use made by any police department of radio was on June 2, 1916, when a private coastal station was established by the New York Police Department, using the call letters KUVS (now WPY) for communication with harbor police boats and for the general policing of shipping in the New York harbor. This station is still in existence, has been modernized from time to time, and is rendering a useful service.

In 1923 the State of Pennsylvania established a system of radiotelegraph stations to provide a means of communication between important police headquarters. With the growth of wire teletype communication the necessity of these stations has been greatly reduced and at the present time they are used primarily in emergencies when wire communications have been disrupted.

As far as is known the first use of radio in the manner in which we are now familiar was by the City of Detroit. Experiments were initiated in this city in 1920 when a radio receiver was installed in a police car and tuned to the broadcast station of the *Detroit News*, the only broadcast station in the city at that time and one of the first in the country. The result warranted further investigation and in 1921 a station was established using the appropriate call KOP.

The early Detroit experiments although partially successful, did not immediately result in a radio equipped police department. The cumbersome receivers and fragile tubes available at the time resulted in unreliability and a high cost of maintenance. However, in 1924, a regular broadcast of stolen automobiles and crime reports was inaugurated, primarily for the use of outlying police departments in the Detroit area.

During the next few years sporadic tests and experiments were made along various lines with a view to determining the most suitable manner of fitting radio into police department needs. For instance, about 1924 the City of New York conducted experiments and purchased some equipment for station house use with a view to establishing a system which would permit, by the use of a suitably designed dial call system, the transmission of a message to all stations simultaneously, to an individual receiver, or to a selected group of receivers.

The early experiments were conducted on the band of

A paper recommended for publication by the AIEE committee on communication. Manuscript submitted March 17, 1937; released for publication March 25, 1937.

EDWIN LEE WHITE is senior radio engineer for the Federal Communications Commission, Washington, D. C. E. C. DENSTAEDT is a lieutenant, and supervisor of radio, in the police department of Detroit, Mich.

frequencies now assigned to the broadcast service. With the growth of broadcasting it became evident that it would be necessary for a separate band of frequencies to be assigned for police activities. This situation resulted in the allocation of 8 frequencies between 1,700 and 2,500 kilocycles by the Federal Radio Commission, which were set aside for use by state and municipal police departments without distinction.

The development of the screen-grid tube and discovery of methods of reducing ignition interference simplified technical difficulties and in 1928 the first successful radio patrol was inaugurated. The remarkable success of this patrol caused the system to spread rapidly. Several cities added this equipment in 1929 and 1930. In 1931 the State of Michigan installed a 5-kw transmitter at Lansing to serve those cars of the Michigan State Police which operated over the lower Michigan peninsula.

At the time the Federal Radio Commission made its first allocation of frequencies it did not appear that specific provision of radio for state police would be a particularly serious problem. However, it quickly became apparent that the allocation of frequencies to municipalities must of necessity be carefully considered and the issuance of authorizations closely co-ordinated if radio facilities were to be made available to all municipalities throughout the country.

It was determined that any plan of allocation must meet the following conditions:

1. It must provide for the issuance of authorizations to any municipality regardless of its location within the United States, or the status with respect to radio of adjacent municipalities.

2. It must be capable of administration in congested areas, such as Philadelphia, Chicago, and New York as well as in sparsely settled districts such as Nevada.

3. Considering the number of frequencies available it must provide the maximum service with the minimum of interference.

In the consideration of the establishment of a system of allocation of frequencies the following principles were used as a basis:

1. It is not necessary that the police cars receive a high quality of service, as long as signals are sufficiently intelligible through interference to ensure accurate reception they are satisfactory.

2. There is a higher incidence of crime in densely populated areas than in sparsely settled districts. Consequently, more messages per thousand population would require transmission in large cities than in rural areas.

3. The poor transmission conditions of the congested areas and the level of electrical noise in such areas require more watts per mile than in the rural districts.

Considering these factors and after much study the United States was divided into areas, the size of the area depending upon the population to be served as well as the density of population. For instance, for all practical purposes the cities of New York and Chicago embody single frequency allocation areas while the whole state of Nevada likewise embodies a single allocation area. Under this plan all cities within a single area are required to co-operate in the use of the area frequency. The power is in general limited by the total population to be served. In order to limit interarea interference a maximum power limitation of 500 watts night, 1,000 watts day is placed on these stations.

It is desirable for adjacent municipalities to pool their radio activities. Provision was, therefore, made for the establishment of a station to serve a number of municipalities and the authorization of power necessary to serve the total area, provided that an agreement was submitted with the application for increased power showing the establishment of a metropolitan area type of system.

Referring again to the frequency-assignment problem, in 1933 as a result of a regional international conference held in Mexico City, frequencies were made available for police use by international agreement. At this time a general readjustment of municipal police area boundaries was made and in addition provision was made for the establishment of state police radio stations. A specific frequency was allocated for the use of the state police of each of the 48 states without reference as to whether the state was at the moment contemplating either the establishment of a state police or of a state police radio system.

Referring to figure 1, which gives the present allocation of frequencies to states, you will note that on an average each frequency is shared among 4 states. The frequencies allocated by the Mexico City conference have been, by agreement with Canada, further allocated as among the United States and adjacent nations. The allocation plan shown in this figure gives due weight to this situation and it is possible for Canada, Mexico, Cuba, and other countries adjacent to the United States to establish police radio stations in the recognized bands for such service and to receive the same quality of service as is rendered by these stations as established in the United States.

Figure 2 shows the existing plan of allocation of frequencies to municipal police stations. As in the case of the state police service shown in figure 1, the allocation shown in this figure also makes provision for the establishment of police stations in foreign countries.

Perhaps the most important effect of the use of radio has been in the growth of a co-operative feeling by the various police agencies of the nation. Possibly because of the necessity for co-operation in the use of radio frequencies a general feeling of co-operation has grown until at present every police officer is willing to give and anxious to receive all possible information which may be available with regard to crime in any adjacent locality.

In line with this co-operative feeling a need was felt for point-to-point communication between police departments. As a result many cities began exchanging communication at night using facilities allocated primarily for communication with mobile units. The service was found to be valuable and resulted in the rapid solution of many crimes which might otherwise have gone unsolved or have had the solution delayed for an extended period.

Approximately 2 years ago the organization "Associated Police Communication Officers" was established and practically the first action of this organization was to recommend to the Commission that steps be taken leading to the establishment of a police radiotelegraph communication system designed to meet the need of police departments for a means of exchanging information. After a

**An automobile equipped for 2-way police radio communication**

The system is operated on ultra-high-frequency channels. The transmitter weighs 20 pounds, has a power output of 5 watts, and its frequency is crystal controlled. To talk from the car, the patrolman merely lifts the telephone from the instrument board and the first sound of his voice puts the car's transmitter on the air. It switches off automatically the instant he ceases talking. The transmitter uses 4 pentodes; the receiver is a 6-tube heterodyne

Western Electric Photo

co-operative study in which not only the Communications Commission but also the police, the Army, and the Navy participated, a system has been established and is now in operation. It is based primarily upon the type of communication system employed by the military services. The same general procedure is used and the same type of control of communication is required.

Under this system the United States is divided into zones, each of which is under the jurisdiction, as far as the use of radio facilities by zone police stations is concerned, of a zone control station. In general, under the supervision of the zone control station, municipalities within the zone are permitted to exchange messages freely with each other. However, messages from zone to zone must be routed through the zone control stations involved for final dispatch. Figure 3 shows the extent to which this system had grown on March 1, 1937. A number of stations have been added since this illustration was prepared.

The Commission will continue its policy of co-operation with the using service in order that modifications may be made from time to time to best fit this new instrument to the hands of police officers.

A few years ago the frequencies above 30,000 kilocycles were deemed to be practically useless. As a result of the activity of amateurs in the band between 56,000 and 60,000 kilocycles it was demonstrated that these frequencies could be quite useful for many types of local communication. The Commission then received requests from certain police organizations for authority to establish stations for use by their police departments on frequencies in or adjacent to the amateur band. After considerable study and consultation with those interested and well informed with regard to the propagation characteristics of the frequencies above 30,000 kilocycles, the Commission authorized 4 frequencies lying between 30 and 40 megacycles which might be licensed temporarily to general experimental stations which were to be operated as municipal police stations. Although licensed experimentally, from the point of view of the police officer in the car these stations were not experimental since they were used for the regular dispatch of police officers in the same manner as if a regular license had been granted. They might perhaps be considered as units in a program of experimental research conducted by the Commission to determine the frequency in these bands best suited to police departments and to determine a number of other engineering questions such as the total number of frequencies necessary to serve the police, the mileage separation which must be maintained between assignments of identical frequencies, and the frequency separation which must be maintained between adjacent channels.

On the frequencies assigned to municipal police stations the establishment of 2-way communication between the police officer in his car and police headquarters has always been prohibited for various reasons, some of which are technical. However, the use of frequencies above 30,000 kilocycles offered an opportunity for the establishment of a 2-way communication system. Although initial installations on these high frequencies were identical in all respects to those on frequencies used by municipal police stations, very quickly a number of municipalities began the experimental use of 2-way police communication. The first authorization issued by the Commission for 2-way police radiocommunication was to the city of Bayonne, New Jersey, on December 22, 1932. On March 1, 1937, 226 cities were operating 1,367 mobile police transmitters providing for such 2-way communication. Of this number of cities 22 made new installations after January 1, 1937.

The experimental program of the Commission on frequencies above 30,000 kilocycles has practically completed one of its phases. On June 15, 1936, the Commission held an informal engineering conference at which time the needs of all the various services were discussed with particular

respect to their needs in the band of frequencies above 30,000 kilocycles. As a result of this hearing allocation plans have been studied and in the near future routine commercial licenses will be issued to various stations to replace experimental licenses outstanding.

## Installations and Equipment of Municipal Police Systems

The installation of police radio equipment in a city is essentially a radio-engineering problem but it is unusual for it to be handled upon a strictly theoretical basis, a compromise generally being made between the ideal and the most economical arrangement. A preliminary survey usually is made to determine if present city owned property or buildings are in a favorable position for a transmitter location and also contain the necessary connections to the police telephone system. Since the average police department has a number of precinct stations, all of course connected into the police wire system, it is generally possible to pick out a building that is in the proper geographical position with respect to the city boundaries and also not in too unfavorable a transmitting location. In 4 cities it has been found necessary to use more than one transmitting station to give adequate coverage. In those cases the transmitting locations cannot be decided upon by considerations of the territory each is to serve alone but also must be considered with respect to one another as well.

In some cases cities have been able to gain some of the advantages of an open location by erecting the transmitting station in a park within a few miles of the district in which a heavy field is desirable. In other cases transmitting stations have been erected in residential sections composed mainly of small homes and fairly clear of large buildings.

In the majority of the early police radio installations the equipment was of composite manufacture. At present, however, radio manufacturers are offering equipment that fits this field and the average installation today uses commercial equipment.

Police radiotelephone transmitters are in general designed for good speech reproduction, but do not need the high standards of fidelity that are built into modern broadcast transmitters. The relay and switching systems must be very sturdy, however, since some of these transmitters are turned on and off over 1,000 times in 24 hours. Standby voltages must be maintained upon the filaments and if rotating equipment is used it must run continuously, it being desirable to have those transmitters come on the air with a delay of not more than one second.

Since the transmitters are used primarily for emergency transmissions, delay in a message becomes serious and it is necessary rapidly to repair the transmitter. To avoid delay a number of cities have installed standby equipment.

The usual troubles encountered are tube, relay, or control circuit failures. Regular inspection and maintenance can reduce the relay and control circuit failures to a minimum.

Fixed receivers at stations offer no particular problems in municipal installations. Antinoise-type antennas are often necessary because of the electrical disturbances originating from call box and teletype circuits in the precinct stations. A simple doublet-type antenna with a twisted pair lead-in is usually satisfactory in such installations.

Automatic volume control may or may not be an advantage. The particular location at which the receiver is to be placed should be studied with respect to this factor. If the station is in an area having a low field strength it may be necessary to use automatic volume control in order to insure reception during periods of low signal. However, in such circumstances a carrier operated antinoise device should be embodied in the receiver in order that the occupants of the station house may not be annoyed by atmospherics and other forms of interference during the time no signal is being received.

The important thing in station receivers is to obtain equipment designed for continuous service. Most cities are using receivers designed for the job and are experiencing little trouble.

The mobile-unit receivers are, however, a different story and practically every department can furnish many woeful tales about their experiences. Troubles with mobile installations are divided between those caused by car ignition, battery, or antenna and those in the receiver itself.

Troubles in mobile police radio receivers are much more numerous than those experienced in broadcast receivers for automobiles. Police re-

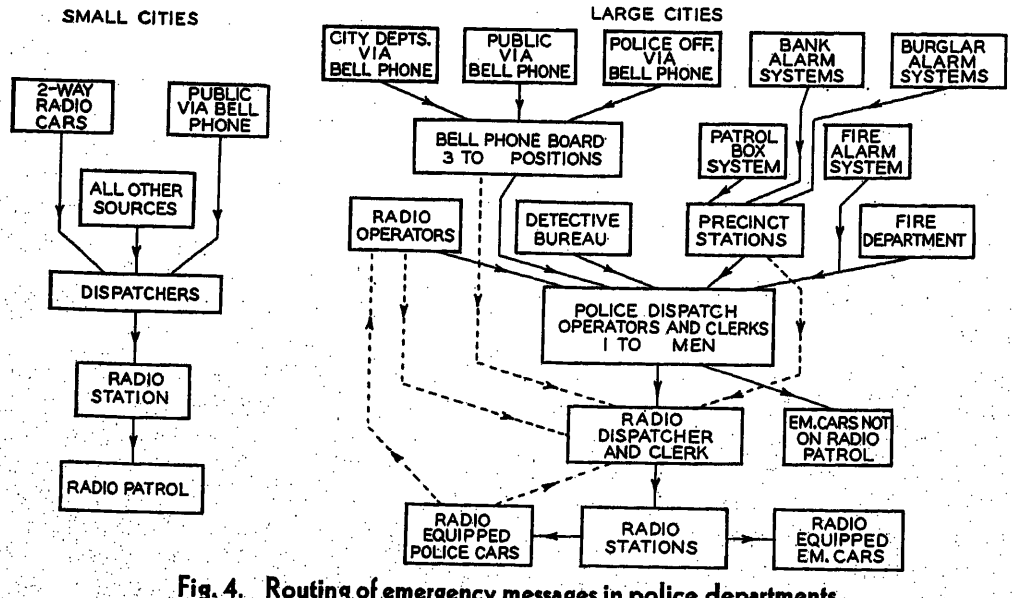

**Fig. 4. Routing of emergency messages in police departments**

ceivers operate 24 hours a day and are mounted in cars that will drive 50,000 to 75,000 miles in a year. Several attempts to modify standard broadcast auto receivers so as to be used in police cars have resulted in disappointment and today the great majority of police departments gladly pay the increased cost necessary to obtain receivers manufactured for police service.

Tube life in police mobile receiver service is now very good, particularly when the cars are equipped with voltage regulated generators.

A life of 1,000 hours is often used as a standard for tubes and vibrating equipment in radio work. While this may represent a life of over one year in ordinary passenger car service, it only represents a life of 6 weeks in police service.

The great majority of police receivers in service use dynamotors for *B* supply, a few using vibrating rectifiers. In general better life has been experienced from the dynamotor and it, in spite of its greater cost, is in greater use.

The detuning or drifting of police receivers, once the greatest single source of trouble, has been fairly well taken care of as far as municipal police work is concerned. State police organizations, however, needing greater sensitivity and selectivity in their receivers, are still experiencing

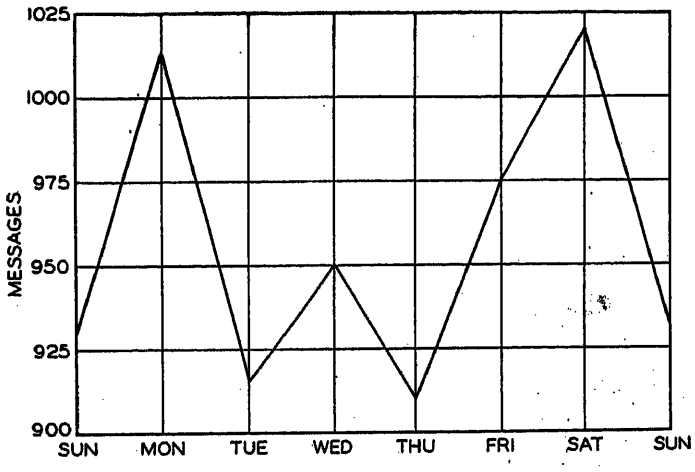

**Fig. 5. Average daily load chart of a representative municipal police radio station**

trouble. In some cases recourse has been made to the use of crystal-controlled receiving equipment.

The average police receiver draws from 4 to 7 amperes from the car storage battery. This drain when continuous and coupled with the fact that police cars cruise slowly would result in discharged car batteries unless special provision is made. Standard generator and battery equipment on automobiles has proved to be inadequate for police radio service and special voltage regulated generators are generally installed on cars for municipal police patrol.

The generator used should be able to balance the radio and ignition load on the car battery at the slowest cruising speed of the cars, usually about the slowest speed at which the engine runs evenly. This varies from 6 to 10 miles an hour. The generators should peak at a speed between 15 and 20 miles an hour and should have a peak current of

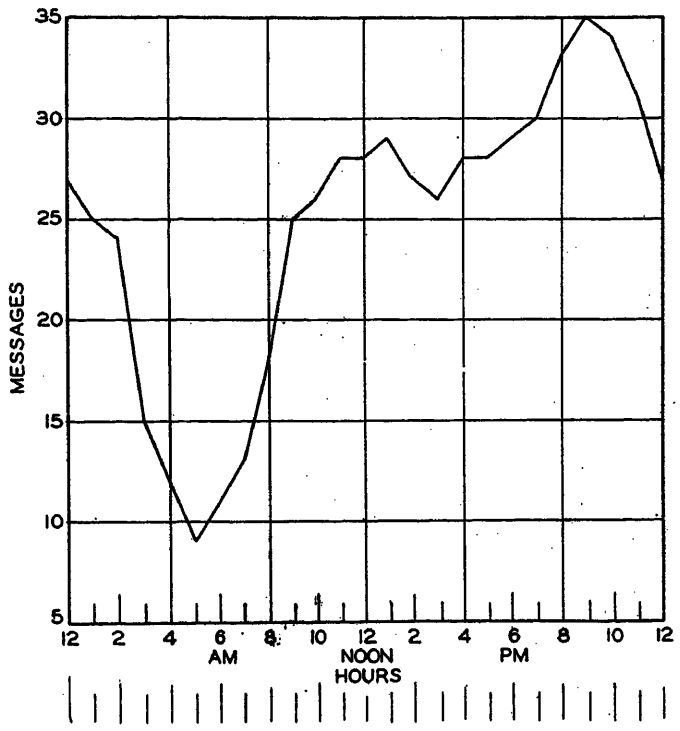

**Fig. 6. Average hourly load chart of a representative municipal police radio station**

from 18 to 25 amperes. They must be equipped with a voltage regulator. Such generators are now commercially available.

It is also considered desirable to advance the battery size in municipal patrol cars in order to carry over periods when it is necessary to leave the radio on but the motor off. Such cases happen quite frequently when car crews are "planted" to watch a car or house.

A screen antenna in the top of the car had proved to be the most satisfactory antenna for police radio work. However, with the advent of the steel top, police were forced to use various forms of undercar antennas, none of which are entirely satisfactory. A better antenna is provided by use of an insulated steel rod rising from the dash, either straight or curved back over the top. The rods, or "fish-poles," are flexible and no harm results from their hitting something.

The reduction of electrical noises set up by the ignition system is accomplished in much the same manner as is standard with broadcast receivers but, because of the higher frequencies used, it is a slightly harder job. Standard spark-plug resistors together with condensers on generators, gas, and oil gauges are used, bonding and shielding are carefully installed. If after an installation is made it is found that ignition noise remains at a high level, different things are tried until the noise is eliminated. As a general rule spark-plug resistors are kept as low in resistance as it is possible to use, since resistors of 25,000 ohms and up have caused some engine trouble.

Some police car receivers have a sensitivity control as well as an audio volume control to take care of the "carrier off" condition. If the sensitivity control is retarded sufficiently to reduce the electrical noise at points

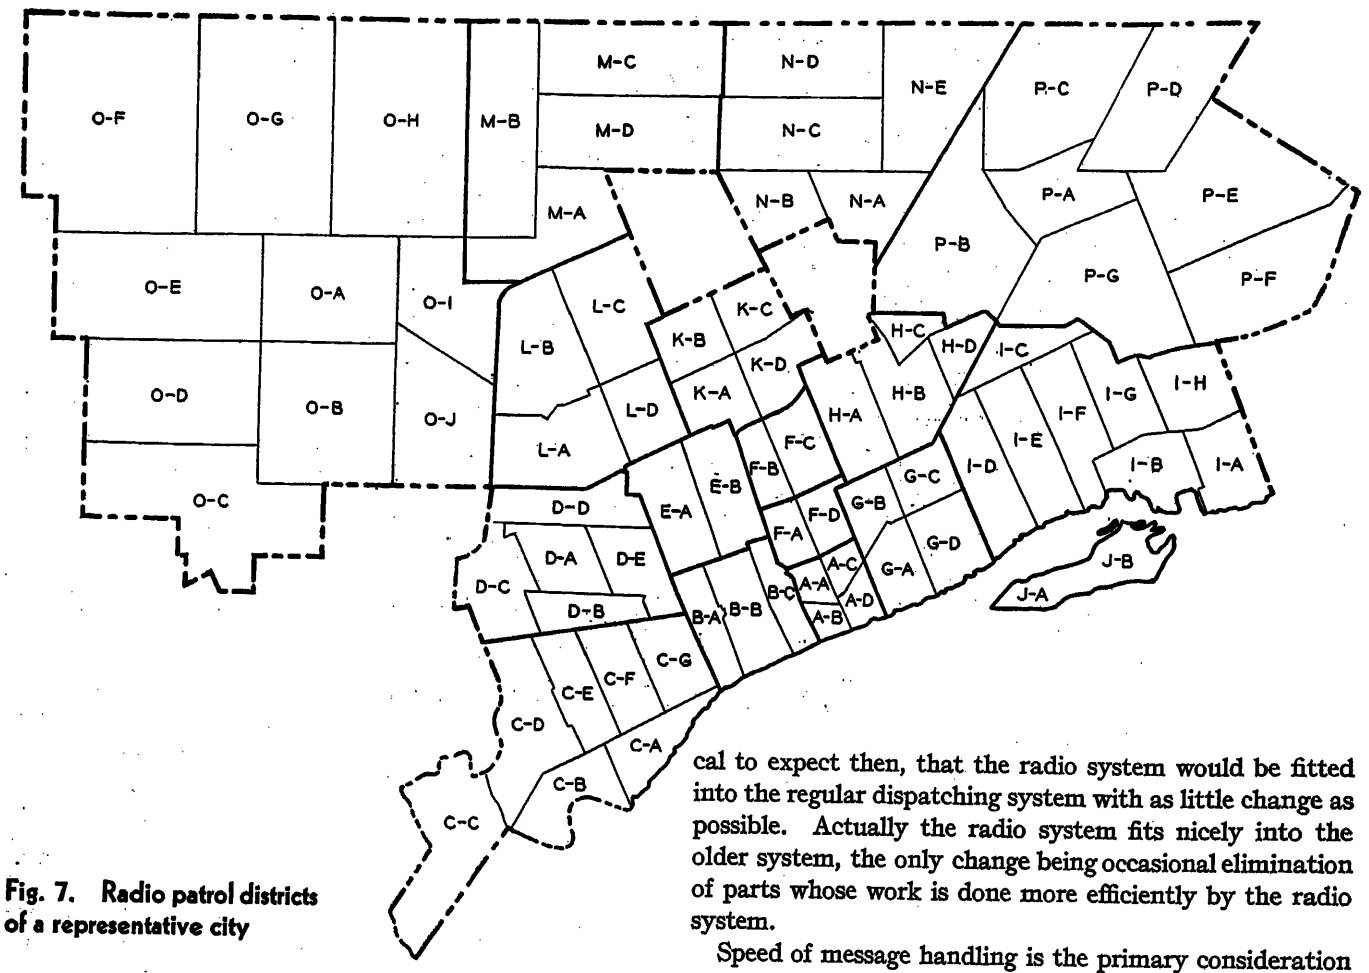

**Fig. 7. Radio patrol districts of a representative city**

in the city where electrical noise levels are high it may also automatically cut out the signal because of the relatively weak radio field from the police transmitter, a dangerous condition in police work. Antinoise circuits have aided in reducing the noise but at best police receivers in patrol cars on busy streets several miles from a transmitter, are rather noisy.

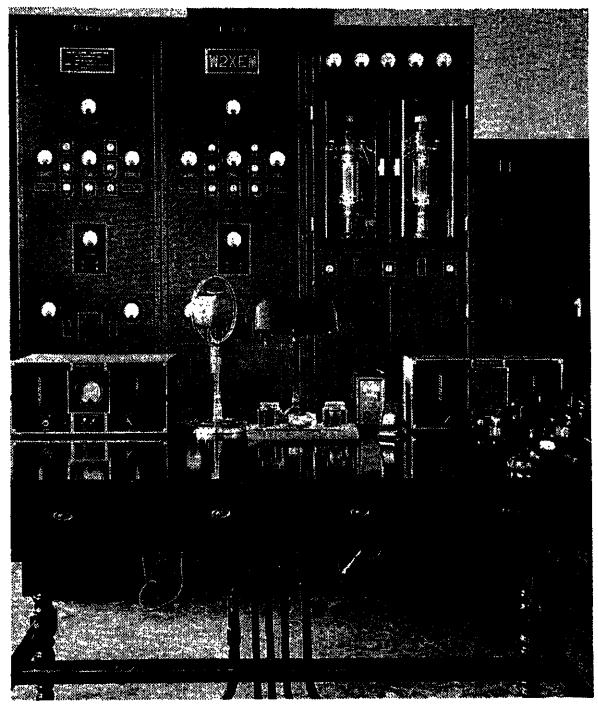
The crews of police cars shade into 2 general classes. One group who keeps the controls turned up and seem oblivious to the noise, the other who keeps the control retarded so much, that when street noises are high they have to turn up the volume to understand the broadcast. Observations indicate that this second group senses the presence of the transmitter carrier by the change of the background noises in the receiver, and, therefore, seldom miss any broadcast information due to the practice of carrying the receivers at low volume settings.

There are some types of men, usually of a nervous disposition, who should not be put on radio patrol cars. The combinations of noises, mental strain due to the presence of a receiver which at any moment may reproduce an order, and the lack of physical exercise have a bad effect on their health. In one of the larger cities the police medical division is at present quite concerned over the problem.

## Operation of Municipal Police Systems

The police radio system is simply a development and extension of previous communication systems. It is logical to expect then, that the radio system would be fitted into the regular dispatching system with as little change as possible. Actually the radio system fits nicely into the older system, the only change being occasional elimination of parts whose work is done more efficiently by the radio system.

Speed of message handling is the primary consideration involved, and of course, a system whereby the person wanting emergency police assistance could call directly to the policeman coming to his assistance would be the ideal method. Obviously this is impossible, yet in smaller towns only 2 intermediate persons are involved, one the telephone operator who makes the connection, second, the police dispatcher who sends the help, figure *4A*. In the larger cities this simple system, although just as desirable, becomes impossible because of the volume of the traffic. It becomes necessary to set up a system similar to *4B* which, while it may look complicated, is as simple as it is possible to arrange and still have a system that will operate smoothly and with rapidity during peak periods.



Figures 5 and 6 show the average load charts of a representative police radio station. Actually these average peaks are increased considerably upon such evenings as Hallowe'en, New Years Eve, etc.

The sources of police information of all natures are extremely numerous, however, the sources of information requiring emergency action are fewer in number. While the detective bureau is shown as a source of information in diagram *4B* the reference is to emergency cases only which are a small part of their activity.

By far the greatest number of emergency requests comes from the public over the telephone system. The incoming telephone switchboard in larger cities thus has to be used in multiple sections so as to allow any one of a number of operators to answer any incoming trunk line. In some cities all incoming calls come in on the one board, in New York, however, emergency calls and routine calls are seg-

regated by having the public call one telephone number when emergency service is desired, and another when making routine calls. Each board, of course, can handle emergency messages in cases where the public makes a mistake.

The switchboard operators handle all routine calls much as any telephone operator. They are trained, however, in proper handling of an emergency call and in how to get the most information from an excited person, and get it reliably. At best the information is none too accurate. The operators then pass this information along to the dispatchers who either broadcast the necessary order or in the largest cities pass it on to another man for broadcast.

**Transmitting equipment of the Newark, N. J., police radio system. Duplicate transmitters, one of which is a stand-by unit, are provided. The unit at the right is the power amplifier, which may be fed by either of the other sets**

The dispatcher's board besides receiving information from the general board may get information from several other points as noted in 4*B*. Bank alarm systems usually are terminated in precinct stations, sometimes in headquarters; fire-alarm systems also occasionally have a wire into the police department and policemen are dispatched simultaneously with fire equipment. Other sources of information include police, via the patrol-box system, precinct stations and substations, radio operators, and fire and other city departments.

It will be noted that the dispatcher has other facilities besides the radio patrol at his disposal. Patrol wagons and other emergency vehicles are kept at precinct stations and substations, and ambulances, pulmotors, etc., at other points. He decides as to what vehicle is to be used, dispatching it or passing the information to the person who makes the dispatch as the case may be.

The dotted lines on diagram 4*B* indicate routes taken by messages of 2 general types. First: routine unimportant traffic with which it is not desirable to load the dispatcher since the emergency dispatch is not involved; second: exceptionally important or "hot" information which must be transmitted without the slightest delay. Most systems are flexible enough to allow some deviation from regular routine in particularly important cases.

The majority of cities have centralized the dispatching authority into the dispatchers. These men and no others are responsible for the proper dispatch of policemen to the scene of a crime, fire, or disturbance. In some cities the dispatcher's word is absolute law in all precincts, and the commanding officer of a precinct cannot move a single emergency vehicle in his own precinct without permission of the dispatcher. This of course means that the dispatcher in addition to being a good police officer, must be familiar with the city, must know the territories patrolled by each car, and must have a continual accurate check upon the condition of each car. The dispatcher is often assisted by a clerk, while various check boards, maps, mechanical or electrical arrangements are used to keep track of the cars. The dispatcher must know where his cars are at all times, whether they are in or out of service, when they are on a run, and when they need radio or garage service. To the dispatcher and his assistants is delegated the job of keeping track of a large fleet of cars. This job is made harder by the fact that these cars are continually prowling about the city doing routine police work on their own initiative while waiting for emergency broadcasts or specific orders. The details involved in this position are considerable and a mistake may mean a missed run or possibly a lost life.

Messages broadcast by police radio stations fall into 4 general types:

1. Emergency dispatches: Orders to a particular car to proceed to the scene of a crime, fire, or disturbance. This is the most numerous and most important of the 4 types of messages
2. General broadcasts: Crime reports, stolen cars, missing person reports, descriptions of wanted persons, etc.
3. Station calls: Routine police work, orders to cars to call their stations, go for gasoline or repairs, take care of a detail or traffic, etc.
4. Intercity traffic: Messages of police nature transmitted to other police radio stations by radiophone

The police radio station exists primarily for broadcast of types 1 and 2. Type 3 is more or less routine and is handled if time permits, while type 4 is not handled at all by some cities. It is expected that police radiotelegraph will eventually handle most of this latter type of traffic.

An interesting point to note here is that because of the general unreliability of information coming from the public, very often a broadcast of type 1, sending a police car to the scene is made before a general broadcast of the crime (type 2). The actual descriptions, etc., are obtained by a policeman from the persons at the scene.

In municipal one-way systems the patrolmen, after having been sent on a run, call back over the police or city phone systems. The dispatcher or radio operator de-

pends entirely upon the car crew hearing the run and obeying instructions. If, however, the car crew does not report back in a specified time after the order is broadcast (from 5 to 30 minutes depending on the city), another car is dispatched.

No system is perfect and occasionally a run is missed. A follow-up is desirable on important runs, therefore, 2 or more radio cars are often sent. In some cities station cars are dispatched by telephone in addition to those dispatched by radio.

The efficiency of the radio equipment is attested by the fact that accidents, car failure, and mistakes made by the operating personnel each result in as high a percentage of runs missed as does failure of radio. Radio failure as a cause of missing runs is of course eliminated by the use of a 2-way system and most larger cities are now experimenting with 2-way equipment. In a 2-way system if the dispatcher does not get an immediate "OK" from the car crew dispatched, he dispatches another car.

As the radio system follows the plan of the precinct signal systems, so are the territories of the radio patrol cars influenced by the precinct boundaries. Each precinct is broken up into patrol territories and a radio patrol car assigned to each. In addition there may be other cars, usually better equipped and carrying a larger crew, who patrol through the whole precinct or through several territories and still other crews and cars that work more or less free lance or on special police problems. Each territory and car are assigned a number and this number alone is used in dispatching. Often individuals are assigned numbers to permit their being called without mention of names.

Figure 7 is a representative layout of the city of Detroit (neither correctly numbered nor accurate) that shows how cars may be arranged in a large city. In this case the actual car numbers are replaced by letters that have no significance.

The patrol districts are chosen systematically with the following factors in mind:

1. Density of population
2. The crime record of the territory under consideration
3. The traffic problem, in which account is taken of the density of traffic, of possible congested points, and of impediments such as railroads, canals, etc. The traffic problem affects the speed of police cars, and therefore, the time required to respond to a call
4. Other police protection. (Such as detectives, traffic officers, etc., in the business sections)
5. Records of the radio station as to the frequency and number of runs originating in the territory considered

By this mehod the available cars are placed where they will result in the most effective patrol.

## Two-Way Police Radio Systems

It seems unnecessary to justify the additional expense of the 2-way system, yet a number of departments have been hampered in obtaining funds for installation of 2-way equipment because of the fact that they have a one-way system in successful operation.

**A view of the equipment at station WRDP, of the Michigan state police, located at Paw Paw**

Certain types of crimes can be solved in many cases if rapid efficient communication can be maintained between the police dispatcher, or radio operator and a crew on the scene. This refers only in part to continuous pursuits, where other cars can be used to block off escape. These are spectacular and have attracted press notice but more important are the cases where information immediately furnished by the car crew on the scene results in a broadcast and a capture by another car crew before a clean getaway can be made. In hit-and-run cases it is often possible to obtain a hit-and-run license number from a crew on the scene, check registration and have another car waiting at the driver's home when he gets there. Since only a few minutes are available, by eliminating the time required for the patrolman to get to a phone and get a connection to the dispatcher or radio operator, 2-way often means the difference between success and failure. Seconds count in police work.

Two-way radio makes the patrol force more efficient. The efficiency of a police department depends considerably upon attention to details. Routine and uninteresting though they may be, they are important. As an example, a patrol car crew passes a parked car, something about it makes them slightly suspicious, if the patrol car is equipped with 2-way communication, in such a case they would call for a check on the license and sometimes find their suspicions are correct. Only once in 100 times possibly, but that once may be extremely important.

Consider now, that the cost of a 2-way system is but a fraction of the yearly salary cost of the patrolmen assigned to radio cars and we see why 2-way growth has been rapid.

Two-way radio systems divide into 2 types, one using ultrahigh frequencies exclusively, the other using a medium high-frequency station transmitter. Cities which are making an initial installation of a complete system now usually install the first type. The second type exists in those cases where cities already equipped with a one-way system add ultrahigh-frequency transmitters to their mobile equipment. There are also certain situations in which

installations of the second type are made due to the fact that the municipality involved has assumed responsibility for the rendition of service to surrounding areas, such as the county, which lie beyond the range of any ultrahigh-frequency transmitter which could be considered.

The method of operation of 2-way systems also varies and can be classified as follows:

1. Simplex operation: One frequency is used for both station and car transmitters. Only one can be on the air at a time, direct car-to-car communication, when the cars are not separated too far, is possible

2. Duplex operation: The station transmitter is on one frequency, the cars on another. Both can talk at once if necessary and operation is similar to ordinary telephone conversation. Car-to-car communications not possible except by rebroadcast through the fixed station (sometimes called triplex)

3. Voice break-in operation: A system using voice operated relays that control transmitter and receiver. In this case one station can break in on the other during pauses in speech. Direct car-to-car communication is also possible in this method under the same conditions as specified in the first case.

In its actual operation the 2-way system does not differ greatly from the one-way system. Calls are received and handled as noted in figure 4. The difference is that return calls from the car crews are made by radio instead of wire. The dotted lines in figure 4*B* from patrol car to dispatcher or radio operator indicates this communication channel. The only possible addition is direct car-to-car communication, which is not shown in the figure.

## State-Wide Radio Systems

The last few years have seen increasing interest in statewide radiotelephone systems and, while state-operated systems are not as yet in operation in the majority of states, the time is not far away when they will be. In some states teletype systems are used while in others a state patrol force does not exist. Parts of states are sometimes given the benefit of radio coverage by arranging with municipalities having transmitters for broadcast of necessary messages, all of which tends to delay state police installation.

The engineering problem involved in the installation of a statewide police radio system differs considerably from that in the municipal police system. Electrical noises, shadows of steel buildings, and high noise levels at certain points provide the major problems in the selection of a site for a municipal police station. However, the problem involved in a state police system is primarily the size of the area to be covered and the average conductivity of the ground within that area. The problem is so involved that it is doubted the selection of the most economic facilities can be based on anything less accurate than actual field strength surveys.

It is characteristic of the frequencies used by state police radio systems that at a more or less definite distance from the transmitter, depending upon the conductivity of the ground pronounced fading occurs which is usually sufficient to make the signals practically useless. Increase in power will not obviate this difficulty The distance at which this so-called fading wall appears is dependent upon the conductivity of the ground and the type of antenna in use. On the basis of a field-strength survey the location of the fading wall can be quite accurately determined, as can the amount of power necessary to place the minimum useful signal at the inner edge of the fading wall. The use of any power beyond this figure is wasteful. Thus some states have found from 3 to 7 transmitters necessary. Figure 8 illustrates the arrangement of the stations in the state of Illinois. This arrangement was determined on the basis of a field strength survey. The circles shown indicate the 100-microvolt contour which was estimated to be the inside boundary of the fading wall or the maximum range at which satisfactory service might be expected. At the present time it is possible to operate the cars at a considerable distance beyond this range.

In selecting transmitting locations for municipal police stations it is the usual practice, as stated above, to select city-owned property as a site for the transmitting station. However, in a state system it is often found economical to purchase new property, erect new buildings, and move existing state police headquarters to the location best

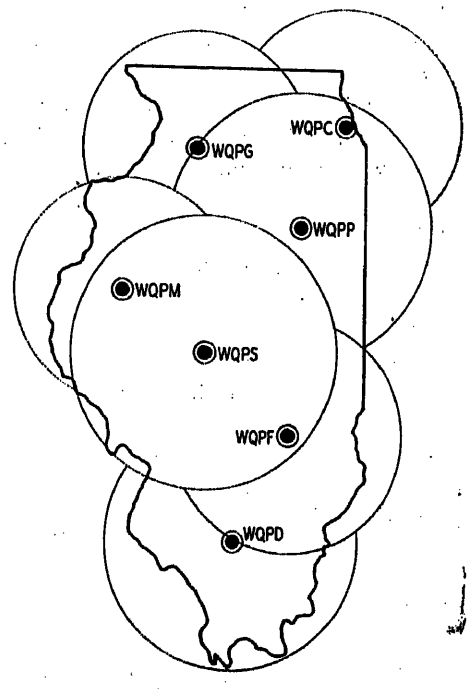


**Fig. 8. Arrangement of state police radio stations in the state of Illinois, showing coverage of each station**

suited for radio transmission. In selecting this location the primary factors to be considered are:

1. The most suitable location for statewide coverage with the minimum number of stations

2. The location of the property as nearly as possible to a highway network center

3. Availability of commercial power and wire communication circuits

The use of a number of transmitters for state police service has an advantage in addition to that of pure economics. Many of the situations that arise requiring the transmission of a message over state police radio stations are of restricted interest and may be handled by the local station. Each of these stations then becomes a unit in a statewide

system and each has its own sphere of activity. This feature results in a strengthening of the patrol, since in major crimes or statewide man hunts all departments act together, usually under the direction of one of the state stations. It may also provide a local police radio service to the county sheriff's officers, or the small communities that would of necessity be unable to afford a system.

Many states are providing, in addition to stations at fixed locations, state police stations located in trucks that can be moved to scenes of disturbance or disaster to operate with a temporary state police headquarters in order that the greatest facility may be had in handling the situation. The utility of this type of installation was amply demonstrated during the recent flood, in which the State of Ohio operated 4 such installations and the State of Indiana 13.

It is necessary where communications are exchanged for each state police station to monitor not only the transmission of the other state police stations within the same state but also those of adjacent states and of municipal police stations in the vicinity in order that in an emergency there may be a facility available for the most rapid distribution of crime information. As an illustration in certain police stations nine radio channels are continuously observed.

Figure 9 illustrates the importance of a state radio system in a communication network. This figure shows the extensive police communication system that has been built up in and around the state of Ohio. Columbus, the control station of the Ohio State Highway Patrol, is the focal point and radio circuits extend from there in all directions.

This figure shows all the various systems of police communication that are in use for intercommunication, including teletype, radiotelephone, and radiotelegraph. Long-distance telephone and wire telegraph are used in emergencies and as extensions of this system. Since ultra-high-frequency stations do not enter this network such installations are omitted as are receiving points not equipped with transmitters. These latter points are very numerous as sheriffs' offices and the majority of cities monitor the transmissions of the state system. There are additional city-to-city circuits in existence within this territory which are not shown since they do not clear messages through Columbus.

The use of radio to set up blockades so as to isolate an area in which a serious crime has occurred is a valuable point in a statewide radio system. The co-operative system in use by Michigan, Ohio, and Indiana is a splendid example; these 3 states have a planned system laid out on maps with which the dispatchers are familiar. Each police car, police post, sheriff, and municipal organization has a part to play in setting up a blockade and knows its duties in advance. Main highways and strategic points such as bridges, etc., are closed immediately, the border between states is sealed by cars and then the hunt in the territory begins. In the case above mentioned the 3 states act in unison whenever a crime is committed near the border, the cars of one state watching certain points while those of the other states watch others. Police organizations of

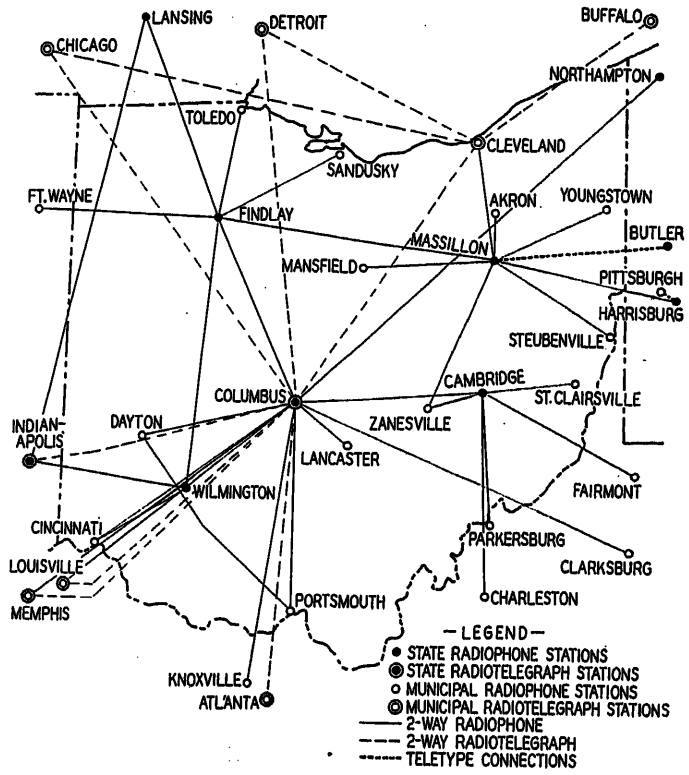

**Fig. 9. Police communication channels in and around the state of Ohio**

these states, numerous counties, and a score of cities participated in a recent successful man hunt and blockade.

As a general rule the state police radio system acts as a clearing house for information regarding automobile-license data and stolen- or wanted-car records. The cities having police transmitters depend upon the state police system to collect and maintain these records as well as to provide access to auto records of the state licensing authority.

In addition, it is generally considered the duty of the state police system to keep a crossfile on criminals working in the state and to advise individual departments of criminals' activities elsewhere.

Summarizing it may be stated that the police departments are using radio for 6 purposes:

1. By municipalities for one-way communication to mobile units and remote police stations
2. By municipalities for 2-way communication with mobile units
3. By states in the general dispatching of state police units
4. By states and municipalities for the radiotelegraphic exchange of police information
5. By harbor police in connection with the dispatching of harbor police boats and general policing of shipping
6. By states for emergency radiotelegraphic use in the event of interruption of the wire teletype network

All of these systems have their peculiar problems and uses. Therefore, no police radio installation should be made until adequate study has been given to the problem, in order that the equipment purchased and installed may suit the situation.

# A New Approach to the Industrial Lighting Problem
## Specific Lighting for Different Services

By H. B. DATES
FELLOW AIEE

Comprehensive surveys have shown the general inadequacy of artificial lighting in industry. The rapid increase of scientific knowledge on the relations of light and seeing has opened a new approach to the specification of lighting for industrial processes involving critical studies of the visual tasks, and the quality and quantity of the illumination needed. Results of the application of this new method are described in this paper.

## Introduction

FOR PERHAPS thousands of years manufacturing was a home industry, pursued only in daytime, and to a considerable extent out-of-doors—the forge under a tree; the loom in front of the cottage.

Learning was the special business for the few; the mass of the human race ignorant and poor, engaged in homely, coarse occupations.

Even after the art of printing was invented and books and periodicals became cheap and abundant, artificial light was costly and scarce.

In the evolution of industry, the change from home to group production in factories, manufacturing, in the absence of any but the most primitive of light sources, was of necessity a daytime occupation but carried on indoors under a tiny fraction of the light out-of-doors. Gains in learning and the supplying of material manufactured necessities were at the heavy cost of impaired eyesight—a large capital expenditure.

## Daylight

It is not generally appreciated, even today, how inadequate, in most cases, natural lighting is for indoor work requiring close, visual applications.

Daylight varies through an enormous range of brightness values. On a June day from as high as 10,000 foot-candles in the sunlight to 200 foot-candles or more just inside the window of a room. It also varies according to the time of day, the season of the year, and the state of the weather. But indoors, 25 feet back from the window, the light may be but $1/40$ or $1/100$ of that on the window sill. In interiors daylight decreases surprisingly fast as distance from the windows increases.

Consider then the conditions for seeing fine details, under natural light, in literally thousands of factories with but moderate window area, wide floors, and often with adjacent buildings shutting out the sky. It is not a question of needing artificial light only at night, but of needing it in most of the work places throughout the day.

## Development of the Lighting Art

The incandescent lamp for the first time in the history of illuminants opened possibilities for a safe, convenient, and inexpensive light.

The excessive brightness of the bare bulbs, with its accompanying discomfort, and fatigue, led to the shielding of the filament from the eye by crude shades which developed into open bottom, inverted glass bowls, metal reflectors, and enclosing glass globes.

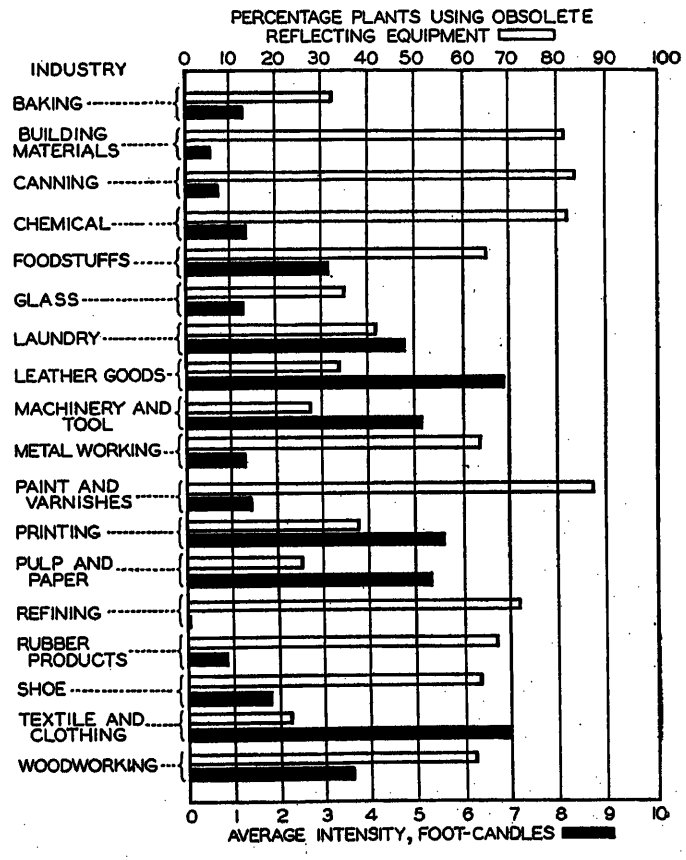

Fig. 1

Gradually as lamps improved and their use enlarged, the art of lighting developed and with it a large variety of fixtures and reflectors adapted to industrial applications.

A paper recommended for publication by the AIEE committee on production and application of light. Manuscript submitted March 8, 1937; released for publication March 18, 1937.

H. B. DATES is professor and head of the department of electrical engineering, Case School of Applied Science, Cleveland, Ohio, and chairman of the industrial and school lighting committee of the Illuminating Engineering Society.

Progress was made in lighting practice as a result of studies on the effect of better lighting on quality and quantity of output, on the prevention of accidents, and the efficiency of workers. However, lighting remained largely an *empirical art* rather than a practice resting on a scientific basis. Lighting specifications were formulated mainly from experience and opinions and tended to emphasize foot-candles, size, and spacing of lighting units, rather than lighting for the best seeing conditions for the visual tasks involved.

## Seeing

The physiology and pathology of the eye have been studied intensively by the medical profession over a long period of years. The correction of refractive errors of the eye has long been on a scientific basis, but only in relatively recent years has serious attention been given to the problems of seeing and the relation of seeing and illumination.

The act of seeing involves many factors; the recognition of outline; of size; of form and detail; the perception of light and shade; quickness of seeing as involved in the observation of rapidly moving objects; the brightness contrast of the object viewed with that of its immediate background and more distant surroundings; color and glare. In addition psychological reactions must not be overlooked.

The influence of illumination on each of these factors must be studied separately; the fundamental laws determined, and methods of measurement and of evaluation developed.

This science of the relations between light and sight has made large strides and while admittedly still incomplete, knowledge has so greatly increased during the last decade that many of the physical, physiological, and psychological factors comprising the complex process called seeing can be appraised and measured; thus there is building up a truly scientific background for the lighting art.

As has been the case in every important scientific advance, so in this field there is a reluctance to abandon old empirical methods. However, the last few years have witnessed a tremendous public awakening to the importance of eyesight and a rapidly growing recognition that the primary objective of light and lighting is to promote the most accurate, comfortable, and easiest seeing and that the production and control of light are but means to this end.

## Prevailing Industrial Lighting Conditions

Of the need for comprehensive studies in industrial lighting there is no question. During the years 1933 and 1934 extensive surveys were conducted throughout the United States to determine the lighting conditions in various industries as well as the average conditions in industry as a whole. In figure 1 and table I are summarized some of the findings of the surveys.

The Federal Census of 1930 listed 220,670 industrial plants in the United States.

It will be noted that as of October first, 1934, 54 per cent of the lighting equipment used in industry was of obsolete types. The average age of the lighting equipment, 8.74 years, and the average level of illumination in the work areas, 2.85 foot-candles.

However, it must not be inferred that all industrial lighting is inadequate. Much good lighting is in use providing excellent seeing conditions, though as yet it represents far too small a percentage.

The surveys further pointed out that there is a lack of proper standards for the satisfactory solution of specific lighting problems; that comparatively few industrial lighting problems have been solved to the mutual satisfaction of illuminating engineers and industrial executives, and indicated the need of fundamental studies to determine the illumination values adequate for all types of industrial processes and the best methods for supplying these values. These

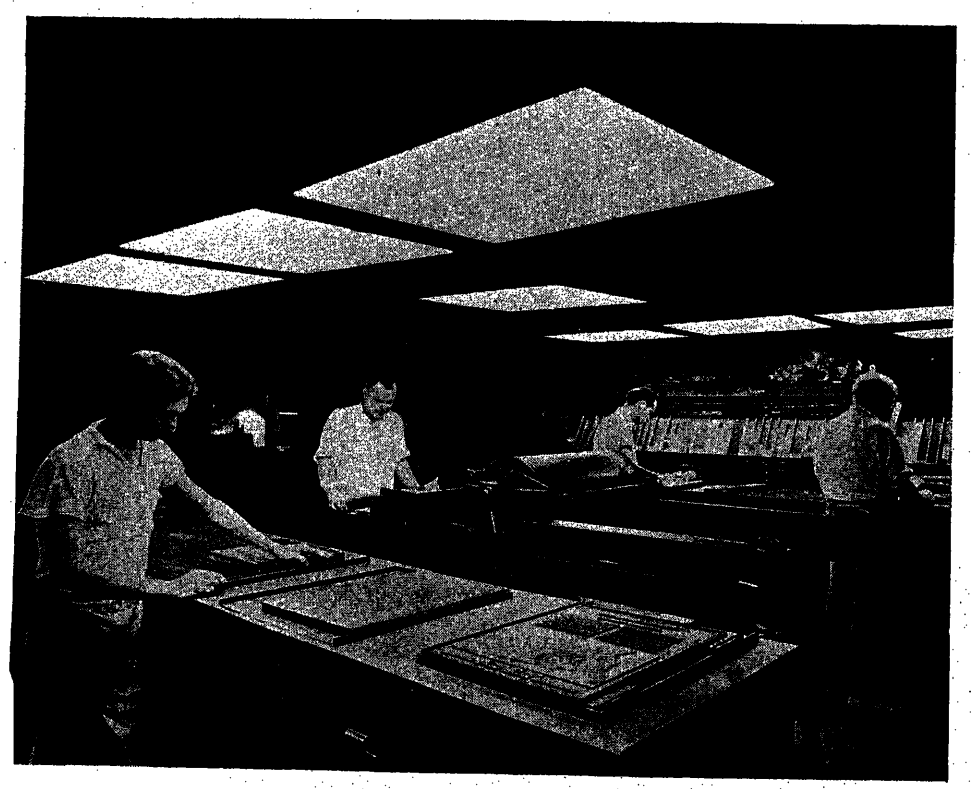

Fig. 2

studies definitely show that good lighting saves eyesight, minimizes accident hazards, reacts favorably on the morale of the workers, decreases spoilage and waste of materials, and is generally effective in improving the quality of finished products.

## New Approach to Industrial Lighting

Thirty years ago industrial plants if provided with any artificial illumination had a drop lamp over each machine or workplace. Sometimes reflectors were used, often lamps were bare and glaring. In those days if general illumination was used at all, there were a few high-powered arc lamps or clusters of carbon incandescent lamps under flat reflectors.

Fig. 3

This was followed by a more or less universal adoption of general illumination methods where medium and large size tungsten filament lamps in scientifically designed reflectors were symmetrically spaced throughout the working area and various levels of more or less uniform general illumination were supplied. Many times these levels were of a decidedly low order and on some occasions reasonably satisfactory for most types of work.

What then is this new approach to industrial lighting? It is to study for each manufacturing process in an industry the visual task; to appraise this task in terms of the fundamental factors of seeing: size, contrast, glare, etc.; to determine the quality of the lighting and the quantity of light needed to perform this visual task accurately and quickly with comfort and ease, and without abuse to the eyes or the frequent results of eye strain noticed as headaches, irritability, and general fatigue; thus is developed as a result—a lighting specification for the process in question, and there then remains the determination of light sources and equipment to produce the specified results.

## Researches in Industrial Lighting

To these ends the industrial and school lighting committee of the Illuminating Engineering Society, 2 years ago, initiated a series of comprehensive studies to determine adequate lighting solutions for industrial seeing tasks. It is the hope that as a result there may eventually be formulated, on as scientific a basis as present knowledge permits, lighting specifications for all of the important industrial operations.

To date studies have been made on:

1. Lighting in the printing industry

Table I

| Classification of Manufacture | Federal Census—Number of Plants of This Type | Average Age of Present Lighting Equipment in Years | Average Foot-Candle Intensity | Per Cent Increase in Light Necessary for Good Illumination | Per Cent of Plants Using Obsolete Reflecting Equipment |
|---|---|---|---|---|---|
| Baking | 15,684 | 7.5 | 1.24 | 195.0 | 32.1 |
| Building materials | 14,792 | 8.1 | 0.5 | 1500.0 | 82.0 |
| Canning | 2,917 | 11.7 | 0.6 | 1150.0 | 83.4 |
| Chemical manufacturing | 8,871 | 9.3 | 1.3 | 208.0 | 81.7 |
| Foodstuffs, candy, dairy | 46,113 | 8.9 | 3.1 | 271.0 | 65.2 |
| Glass | 8,478 | 5.6 | 1.2 | 460.0 | 35.0 |
| Laundry | 21,926 | 5.5 | 4.75 | 139.0 | 41.3 |
| Leather goods | 4,796 | 6.5 | 6.88 | 62.5 | 33.7 |
| Machinery and tool manufacturing | 11,807 | 6.57 | 5.1 | 106.5 | 27.3 |
| Metal working | 12,021 | 9.57 | 1.3 | 562.3 | 63.7 |
| Paints and varnishes | 923 | 17.1 | 1.4 | 494.0 | 87.3 |
| Printing | 22,725 | 5.4 | 5.5 | 109.8 | 37.6 |
| Pulp and paper manufacturing | 3,783 | 10.0 | 5.29 | 193.0 | 25.0 |
| Refining | 2,906 | 6.8 | 0.02 | 592.5 | 72.0 |
| Rubber products | 498 | 7.2 | 0.8 | 496.0 | 67.3 |
| Shoe manufacturing | 1,460 | 4.3 | 1.8 | 263.0 | 63.4 |
| Textiles and clothing | 24,443 | 5.3 | 7.0 | 115.2 | 21.3 |
| Woodworking | 16,527 | 4.0 | 3.6 | 367.0 | 62.4 |
| Totals and averages | 220,670 | 8.74 | 2.85 | 404.7 | 54.0 |

5. Lighting for radio assembly and inspection and small parts manufacturing

According to the complexity of the industry, these studies represent from 8 months to 2 years critical and painstaking study by very competent groups of engineers. It is not claimed that they are completely exhaustive for any one industry, but as more are completed, investigations of the processes in one industry begin to overlap into other industries and progress becomes more rapid —the coverage more complete.

The projects which have been completed have been exceedingly valuable to that particular industry. In each of the completed studies it has been found that by providing proper quality of lighting and quantity of light, the ease and speed of production have been enhanced. The better morale of the workers and their lack of eye fatigue have been manifested in the amount of work accomplished. The value of this method of approach is further evidenced by the rapidly growing application of these methods by competent, progressive lighting engineers, to the large number of industrial and other lighting problems which they are called upon to solve in their daily work.

In providing good quality lighting at adequate levels of illumination, it has often been necessary, for economic reasons, to supplement general lighting by localized installations. The status of the art at the present time indicates that where more than about 50 foot-candles are needed, it is often more practical and economical to secure and control the higher level of illumination needed for good vision, by the use of supplementary lighting for the relatively small work areas involved. However, where such supplementary lighting is used, seeing conditions are impaired rather than improved if the brightness of the area being illuminated by the supplementary units exceeds too greatly the brightness of the surroundings. The absolute permissible brightness ratio is still a subject of investigation, but current practice tends not to exceed a ratio of 10 to 1.

In making recommendations for lighting specific processes, instances occasionally arise where existing equipment is not adequate or adaptable to meet the lighting requirements. Equipment designed for a particularly difficult task often is found highly suitable for other applications not previously realized.

It is obviously impractical here, due to space limitations, to quote in detail from the Illuminating Engineering subcommittee reports. It is the author's principal desire to give the AIEE members a general picture of how the specialist or the illuminating engineer now tends to approach the problem. Lighting is a specialized branch of electrical engineering and much valuable data on the subject is to be found in the *Transactions* of the Illuminating Engineering Society. It is recommended, therefore, that the electrical engineer who is not a specialist in lighting refer to these *Transactions* when he wishes specific and detailed information on particular subjects. In the references are given some of the most recent and vital presentations along specific lines.

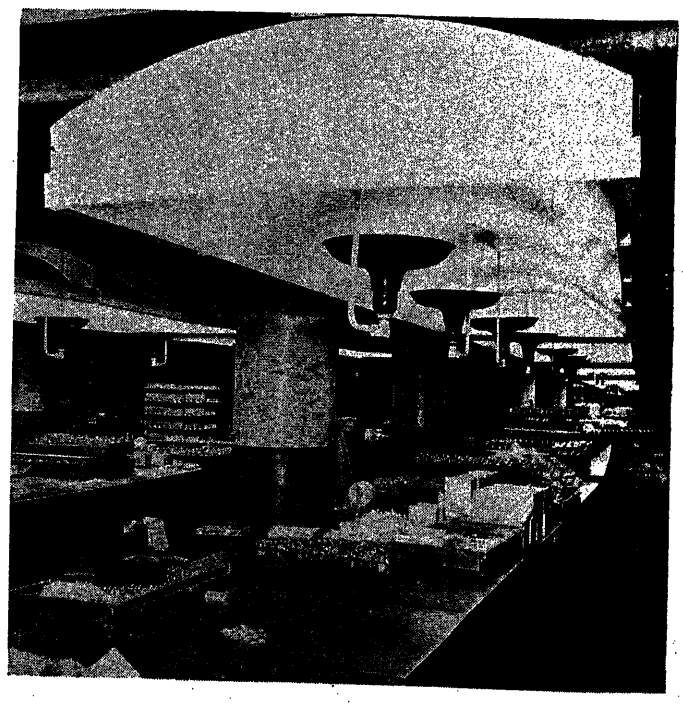

Fig. 6

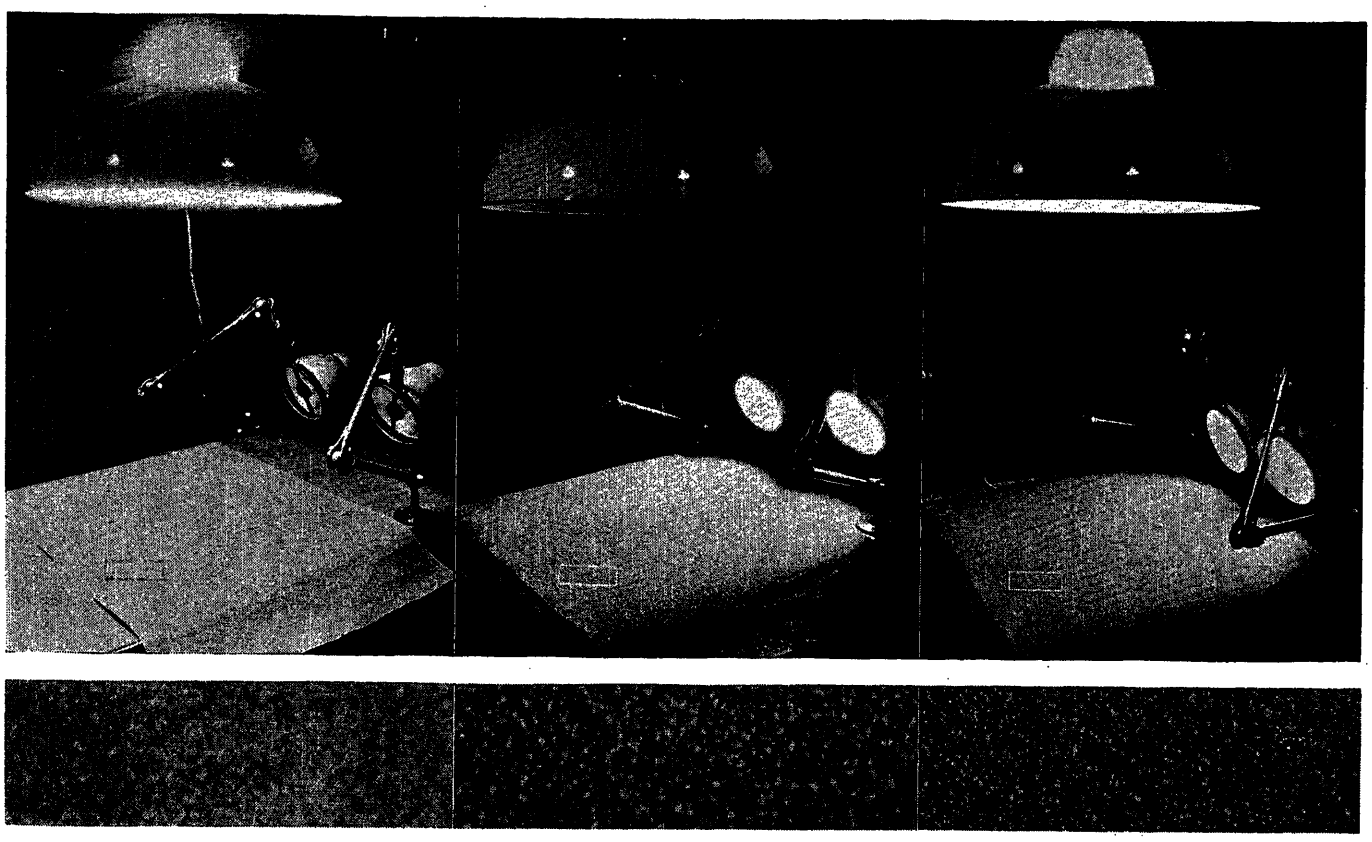

**Fig. 7A. Diffused quality of light, even though of 100 foot-candles intensity, does not show defects but washes out detail**

Diffused lighting, 100 foot-candles

**Fig. 7B. Directional light from an oblique angle and from one direction plainly reveals the wrinkle defects**

Oblique lighting, 13–15 foot-candles

**Fig. 7C. Combination general and oblique lighting. With considerable diffused lighting to approximate general daylight conditions in factory, defects still show up plainly under sufficient oblique component**

Diffused—30 foot-candles
Oblique—15 foot-candles

An appreciation of the value of this new approach may be enhanced by a few examples of its application to the solution of fairly difficult visual tasks.

In the printing industry critical studies of seeing type indicated that the ideal lighting should be from a large area, low brightness light source, giving a highly diffused light with an illumination of the order of 50 foot-candles. Figure 2 shows an application of this quality of lighting to the lighting of type cases, proof press, and page form, composing stones in a large newspaper plant, while figure 3 illustrates how a large light source of low brightness is effective in reducing the reflections from the surfaces of highly polished cylinders upon which are etched the various illustrations and type matter which will appear in a printed rotogravure page.

In the cotton textile industry, the weaving of grey goods presents difficult seeing tasks due to lack of contrast between the thread and the warp and finished cloth. The operator must locate and repair broken ends and see the finished cloth exceptionally well so as to locate defects and determine if all the factors contributing to the production of first-class cloth are functioning properly. Shadows on the work area are particularly annoying. The position of the lighting unit, and the quality of the emitted light have a tremendous effect on the clarity with which details are revealed.

Good general lighting is not always sufficient in itself to provide adequate seeing conditions where most needed and supplementary lighting must be supplied. Figures 4 and 5 illustrated the improvement in punch-press lighting by the addition of local lighting to the general lighting.

Inspection processes frequently present difficult lighting problems. For example: It was necessary to detect small defects such as scratches and buffed-through places on small chromium plated parts. To detect the defects rapidly it was found necessary to have the light highly diffused, with a minimum of glare and an illumination of the order of 50 to 60 foot-candles. The problem was further complicated by the large areas involved. The solution adopted is shown in figure 6.

A manufacturer of abrasives had a very difficult inspection problem, inability to detect defects in the finished product causing expense in rectifying mistakes and a considerable loss of business. In spite of rigid inspection of all the grades of sandpaper passing over inspection tables at a slow rate of speed, and being constantly watched by expert observers, the defects were slipping by, and not showing up until the eventual customer had installed this abrasive sheet upon his automatic machinery. Then an uneven abrasion appeared on the veneer or other

surfaces and caused no end of trouble in attempting to turn out a uniform product. This always produced a retroactive effect on the abrasive manufacturer by causing an expense in adjustment as well as a loss of good will. Many times, it meant an abrupt termination of a contract. Under the general conditions of factory lighting with a good daylight component, these defects were unable to be detected.

The problem consisted of seeing the small wrinkles in the abrasive sheet, which cannot be seen under ordinary general lighting. The wrinkles occur during the process of putting the abrasive on the cloth or paper background. Since the abrasive consists of small jagged particles, which have specular surfaces, general lighting, with its components of light from every direction, causes a multitude of reflections toward the eye, so that the net effect is to see a mass of abrasive surface without seeing any minute detail. Since the light penetrates into the slight hollows as well as on to the high spots, the reflections are uniform from the depressions as well as from the rest of the surface, so that the depressions or wrinkles cannot be distinguished. However, with very oblique lighting, with the rays of light just grazing the surface, the light impinges upon the higher surface, but completely misses the depressed wrinkles. This causes a shadow in the depressions, so that the wrinkles can readily be seen.

The 3 photographs (figures 7*A*, *B*, and *C*) illustrate 3 steps showing the procedure in solution of the lighting problem.

Figure 7*A* shows that even with a high intensity diffused quality of light, the defects did not show up, but on the contrary were obliterated.

Figure 7*B* demonstrates the fact that directional light from an oblique angle, and from one direction, plainly revealed the wrinkle defects.

Figure 7*C* illustrates the typical conditions under which the abrasive sheet will be seen under the proper lighting. It shows a combination of general lighting of a diffused nature, of about 25 foot-candles and an oblique component of light, of approximately 15 foot-candles. There is sufficient quantity of oblique light to still plainly show the defects, despite the tendency of the general lighting to fade them out.

If progress in industrial lighting has, in the past, been relatively slow, it may be attributed in part to a lack of proper standards for the satisfactory solution of lighting problems, and in part to the lack of appreciation of the value of good lighting not merely from the standpoint of production, but of its effect on human efficiency, human welfare, and eyesight conservation.

Much real progress is being made and the next few years will undoubtedly witness greater progress in industrial lighting than has resulted during the last 20 years.

## New 1,000-Watt Bipost-Base Lamp

A rugged 1,000-watt general service lamp, equipped with a medium bipost base and an inside-frosted tubular bulb, recently was developed. The bulb is made of special heat-resisting hard glass which resists shock; and because of an extremely low coefficient of thermal expansion, such temperature changes as result from rain, snow, and sleet have been found in tests to cause no breakage. The bipost base offers the advantages of more accurate focusing of the filament, a simplified socket, and more dependable electrical contact; production also is simplified. The comparatively small size of the lamp makes possible the design of luminaires of relatively high efficiency and small size. Two screens or grids mounted above the filament within the lamp collect much of the normal blackening which in usual lamps is deposited on the bulb; the lamp shown in the illustrations, of course, is designed to be burned base up. The simplified production is said to result in reasonable cost.

# Expulsion Protective Gaps

By W. J. RUDGE, JR. ASSOCIATE AIEE  E. J. WADE ASSOCIATE AIEE

EXPERIENCE with the expulsion protective gap since 1932, when the first commercial installation was made, has demonstrated the efficacy of this device as a means of improving service by preventing lightning outages on overhead transmission lines.

The expulsion protective gap (figure 1) consists of a weather-resisting "textolite"-wrapped fiber tube, whose ends are fitted with metal electrodes. The lower electrode has an opening through which the gases generated by the power arc are expelled. The breakdown voltage through the tube is less than that of the insulator which is in parallel, hence the lightning discharge is kept within the tube. This prevents damage to the insulator, either from the lightning or the power arc, which would result if the tube were not present. The lightning arc through the tube establishes a path for the power current which flows until the next normal current zero, at which time the expulsion action in the tube prevents further flow of current. The tube is isolated from the line by a series air gap which prevents full line-to-ground voltage being applied under continuous operation.

Expulsion gaps are particularly applicable on grounded-neutral circuits. Their ability to prevent lightning flashovers of insulators and the resulting outages and possible damage to the insulators is not dependent upon tower-footing resistance. They are equally applicable on low- and high-voltage lines. To date they have been applied on circuits ranging from 13.8 kv to 138 kv (figure 2). Experience is being obtained with installations on a 230-kv line.

Several of the major applications have been made on 138-kv systems which already had overhead ground wires and insulation consisting of 10 disk insulators. In these cases, the lines passed through areas where it was difficult to obtain the low tower-footing resistances, which are essential for proper operation of the ground wire, without considerable expense. Expulsion gaps were placed on each tower as a means of preventing insulator flashovers and subsequent experience has proved the application to operate as expected. They have also been applied to circuits varying from 13.8 kv upward, both on lines with and without overhead ground wires. Economic considerations show that in many cases they can be applied to each insulator string at a lower cost than that of lowering the tower-footing resistances by addition of counterpoises, ground rods, etc.

Expulsion protective gaps have been found particularly valuable as a means of protecting pole-top switches and river crossings. Often pole-top switches have a lower line-to-line and line-to-ground flashover than the adjacent structures on the line, making them a susceptible point to lightning flashovers. Also, pole-top switches are often used as emergency ties operated normally in an open position, which means that they are located at a reflection point and therefore subjected to higher voltages. River crossings frequently have taller structures and longer spans than normal, which means greater exposure to lightning. On several river crossings the use of expulsion gaps has not only eliminated circuit outages but has prevented damage to the insulators as well.

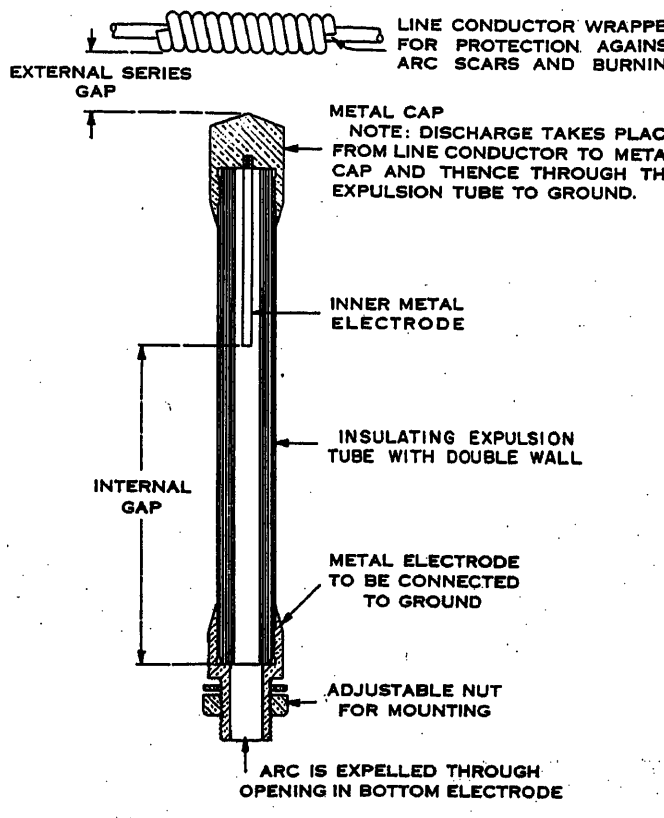

**Fig. 1. Construction of expulsion protective gap**

Where it is found necessary or desirable to obtain the best available lightning protection in important stations, expulsion gaps used at the line end of the shielded zone (approximately 2,500 feet long) adjacent to the station, serve to limit the magnitude of the surge voltage which can be transmitted over the conductors to the station lightning arresters. In some cases it is difficult to install an effective shielded zone for the distance of 2,500 feet from the station. Expulsion gaps installed on all structures out

A paper recommended for publication by the AIEE committee on protective devices. Manuscript submitted March 20, 1937; released for publication March 26, 1937.

W. J. RUDGE, JR., is an electrical engineer and E. J. WADE is a research engineer in the lightning arrester department of the General Electric Company, Pittsfield, Mass.

1. For all numbered references see list at end of paper.

from the station for a distance of approximately one-half mile will provide parallel paths to ground for the lightning currents and will reduce the severity of the stroke currents which must be handled by the station arresters. By using this means of discharging a part of the direct stroke currents to ground the voltage wave will be chopped and its length greatly reduced, so that protection will be secured for strokes which might otherwise result in damage to the station equipment. The gain which can be obtained in either of the above cases is greatest for lines with unusually high line insulation, such as wood pole lines having large spacings, and no guy wires.

Expulsion gaps give the best lightning protection when installed on every structure. However, in several instances it has been found that a material reduction in outages can be realized by equipping only the guyed poles. In other cases it has been found economical to equip a particular section of line or a feeder where lightning troubles have occurred frequently. When they are not installed on all structures, it is essential that the expulsion gaps have low-resistance grounds, to gain maximum effectiveness in reducing stress on the adjacent unprotected structures.

## Volt-Time Flashover Characteristics

Expulsion protective gaps have a somewhat flatter volt-time flashover characteristic than plain rod gaps or disk insulators. The volt-time characteristic of a 115-kv expulsion gap is compared with that of a rod gap in figure 3. It may be noted that the expulsion gap is equivalent to a rod gap having a 34-inch spacing on the full $1^1/_2 \times 40$ positive wave. However, when tested on a wave rising to flashover at the rate of 1,000 kv per microsecond, the expulsion gap is equivalent to a 22-inch rod gap. A similar situation exists with regard to disk insulators. When tested in parallel with a string of 6 disk insulators, the expulsion gap was found to give protection on the full $1^1/_2 \times 40$ positive wave. However, when tested on a wave rising at the rate of 1,000 kv per

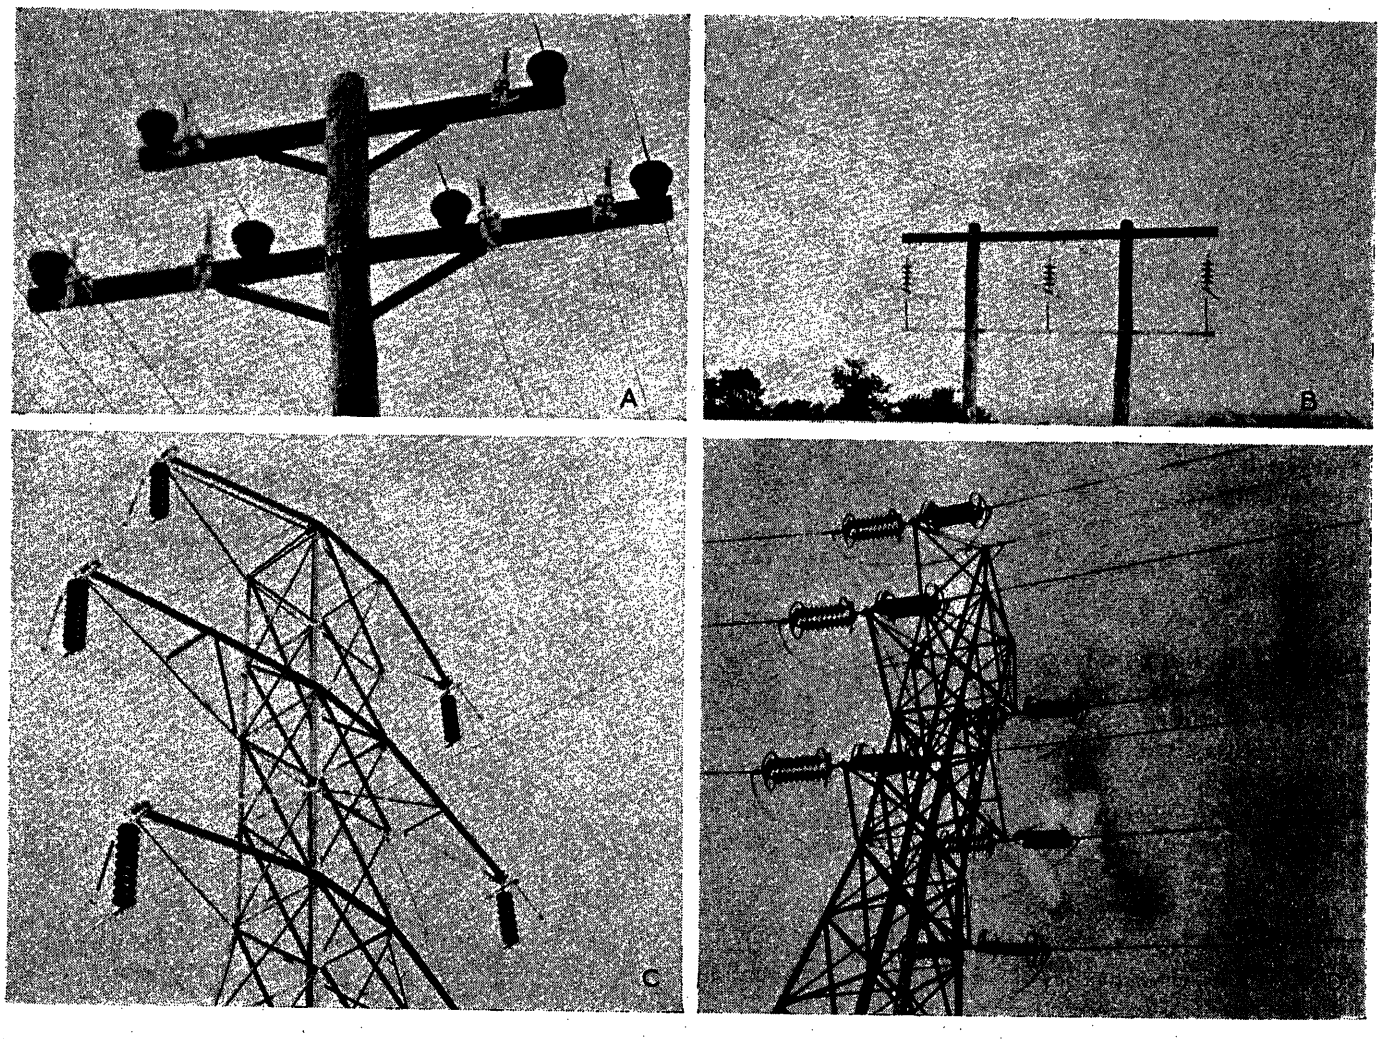

**Fig. 2. Typical installation of expulsion protective gaps**

*A*—13.8-kv system *B, C*—69-kv system *D*—138-kv system, gap on one phase during tests

second, the expulsion gap protects 5 disk insulators which have been made on various combinations of sion gaps and disk, pin, and pedestal insulators, te that where protection is obtained on the $1^1/_2$ x 1 positive wave, protection will also be obtained for ive waves and waves rising in shorter times. Wave ty has little effect on the flashover voltage of the sion protective gap.

e expulsion gap does not have a sufficiently flat ime characteristic to make it suitable for protecting ormer insulation. Comparative tests between the ver characteristics and the breakdown strength of tion pads such as used in transformers, show that ash over of the expulsion gap rises more rapidly than reakdown voltage of insulation pads, as the time to ver becomes less.

en installing expulsion gaps, it is necessary to allow iable tolerances in the settings of the series air Obviously, increasing the series gap raises the ver voltage. Figure 4 shows how the protection of a 115-kv expulsion gap is increased as the series s raised from 11 inches (the standard setting) to ches. To estimate the increase in flashover voltage, from a rod-gap curve, the spacing corresponding to expulsion-gap voltage ($1^1/_2$ x 40 positive wave). o this spacing the number of inches by which the gap is to be increased. From the rod-gap curve the voltage corresponding to the larger rod-gap ig. This will be a close approximation for the tion level of the expulsion gap with increased gap spacing.

## ulse Discharge Characteristics

view of the increased amount of data on direct e currents, it is of interest to speculate as to the bility of an expulsion gap tube being burst by direct e currents. Laboratory tests have shown that its in excess of 100,000 amperes are required to burst the tubes. Lewis and Foust have shown that only one per cent of the 358 strokes measured have tower currents exceeding 100,000 amperes. A similar investigation in Germany, in which 224 strokes were reported, showed a maximum tower current of 70,000 amperes. It appears, therefore, from these data that the probability of an expulsion gap being burst from lightning is very small. Furthermore, field experience with many thousand expulsion gaps over the past 4 years has yielded only $^1/_{40}$ of one per cent where the evidence indicated that the lightning current was great enough to cause bursting.

## Operating Characteristics of Expulsion Protective Gaps

In addition to providing a discharge path for lightning to earth, the expulsion gaps must be capable of interrupting the power current which flows after the lightning discharge. The maximum power current which they will safely interrupt depends upon the pressure generated in the fiber tube by the arc current. An extensive series of tests has established the relation governing the pressure generated as a function of the particular design, the physical dimensions of the fiber tube and the crest current. This makes possible the determination of the tube dimensions for any particular current (figure 5).

Since the test data is of necessity taken and correlated against crest current, it becomes necessary to convert the current values to corresponding symmetrical root-mean-square values when applying expulsion gaps to a given system. When making the conversion from crest current to the equivalent symmetrical root-mean-square value, it is necessary to apply a factor which takes into account the transient d-c component and the wave form occurring in the first half cycle of current flow. If the resistance of the circuit is zero, and the current

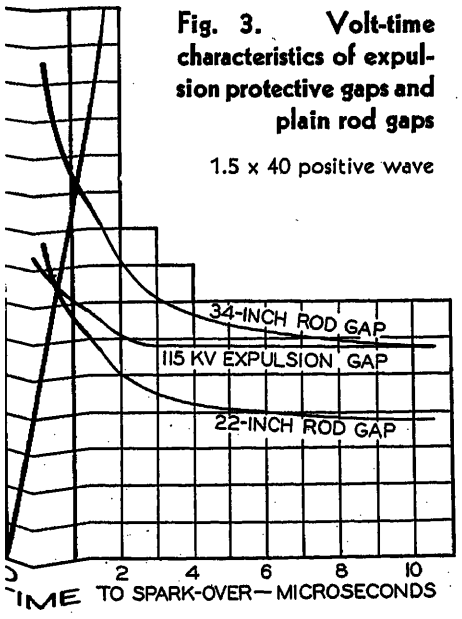

**Fig. 3. Volt-time characteristics of expulsion protective gaps and plain rod gaps**

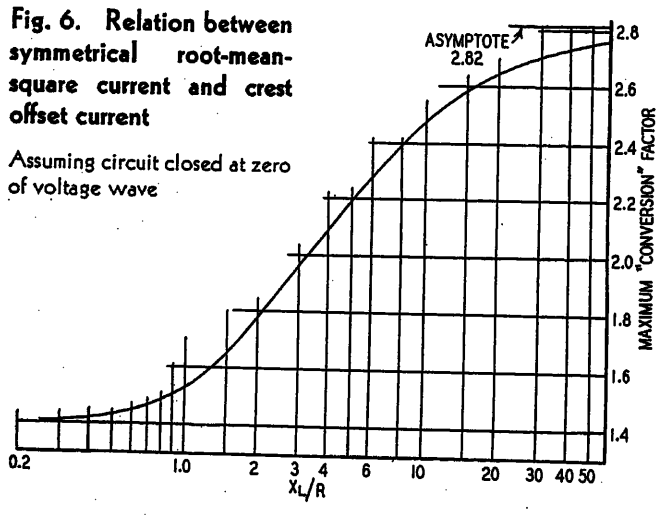
1.5 40 x positive wave

**Fig. 5 (right). Maximum currents for expulsion protective gaps**



flow starts at the zero of the voltage wave, this conversion factor has a value of 2.82. However, the resistance always has a finite value and if the lightning occurs exactly at the zero of the voltage wave, follow current will not be started. Therefore, this maximum conversion factor will never be obtained. The available data from systems on which short-circuit tests have been conducted indicates that the maximum conversion factor in service does not exceed 2.4 which corresponds to a ratio $x/R$ of 8.2 (figure 6). The ratio of $x/R$ is the relation between the inductive reactance (i.e., the transient reactance or that reactance which is effective during the first cycle of current flow) and the resistance of the circuit. The curve shown in figure 6 gives the maximum conversion factor in a single phase circuit where the current is assumed to start at the voltage zero.

It should be noted that measurements of short-circuit currents having a duration of $^1/_2$ cycle, using bushing-type current transformers whose ratings are satisfactory for metering and relaying are likely to be in error due to core saturation as the result of residual magnetism and overloading. Staged tests made where a special current transformer was used in series with a standard bushing current transformer showed differences greater than 400 per cent. This does not mean that differences of this order will exist in all cases, but it does indicate the necessity of eliminating this source of error when determining the current which is the basis for selecting the expulsion gap.

It is always advantageous to select the expulsion gap whose rated maximum current is only slightly above the maximum available system current, as by so doing the minimum or required clearing current can be kept to its lowest values, thereby extending the range of system conditions for which the expulsion gap is applicable. The advantages are twofold. First, the expulsion gap selected can be used in locations where the available short circuit current is lower, i.e., on structures having higher tower footing resistance, or systems with greater neutral resistance. Second, the expulsion gaps will be capable of a greater number of operations before erosion of the fiber raises the minimum or required clearing current beyond the point of successful operation.

**Fig. 6. Relation between symmetrical root-mean-square current and crest offset current**

Assuming circuit closed at zero of voltage wave

In a given circuit there are 3 factors which determine whether or not a particular expulsion gap will extinguish the arc in one cycle:

1. The current
2. The crest value of the (recovery) voltage which appears immediately following the power current zero
3. The rate of rise of the recovery voltage

Figure 7 shows the relation between the recovery voltage which an expulsion gap can withstand and the current during the preceding half cycle. It is apparent from these relations that the minimum current or the current required to clear depends upon the circuit characteristics. The application problem, therefore, becomes one of determining the short-circuit current and the recovery voltage of the particular circuit being considered.

## Circuit Characteristics

A number of papers dealing with the recovery voltage characteristics of circuits have been presented before the Institute.[1–6] However, most of these papers have dealt with this problem in connection with oil circuit breakers, in which very high rates of recovery voltage were encountered. In the case of expulsion gaps, the recovery rates obtained in service are much lower than those for breakers. This is true because the capacitance of the line or line to earth is always in parallel with the gap. In the case of simple 3-phase circuits a fair determination of the recovery voltage can be made by calculation, however, with an extensive interconnected network, the calculation of recovery voltage becomes very complicated. Much less effort and time are required to determine the recovery voltages by test. Furthermore greater confidence can be placed in the test results, as they do not involve any assumptions. Extensive tests on a number of systems form a background of knowledge for applying expulsion gaps. Therefore tests are not necessary in every case to insure a successful application.

## Field Tests

To facilitate the determination of recovery voltages on power systems, and to obtain other fundamental data on operating systems, a truck has been equipped with the apparatus suitable for field testing.

The truck is equipped with the following:

1. An automatic 3-element cathode-ray oscillograph shown at left on figure 8 which may be used to measure current or voltage on three phases of a system. The oscillograph utilizes a rotating drum type film holder, the speed of which can be varied, and a thyratron-controlled circuit which may be adjusted for different exposures. Records can be obtained from a high film speed corresponding to 25 microseconds per millimeter down to speeds which can be successfully recorded by the magnetic oscillograph.

The oscillograms are obtained by photographing the phenomena on the fluorescent screen of the cathode-ray tube using $f$ 2.0 lenses

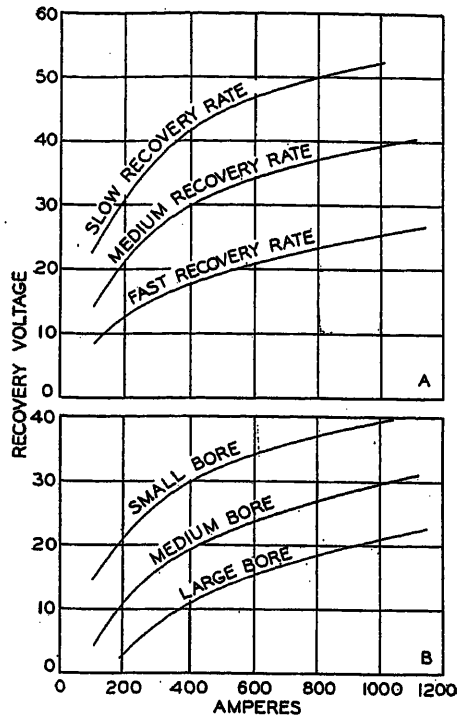


**Fig. 7. Effect of bore and recovery rate on clearing current**

*A*—Varying recovery rate—bore constant
*B*—Varying bore—recovery rate constant

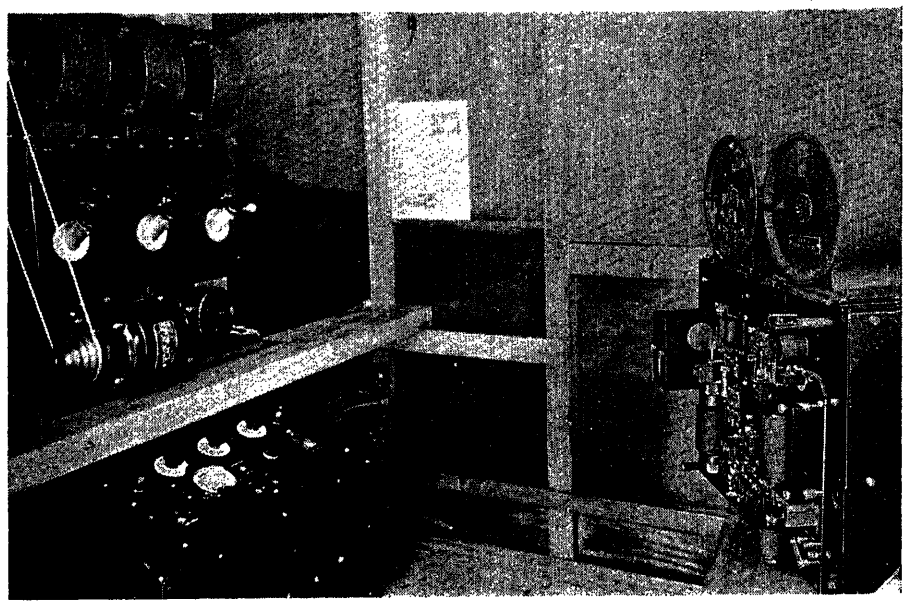

**Fig. 8. Interior of truck for making field tests. View showing 3-element cathode-ray oscillograph and 6-element magnetic oscillograph**

and 35-millimeter "cine" film. The magazine film drums hold 100 feet of film, and means are provided for cutting off the exposed portions after each test.

Porcelain-housed coupling capacitors are used as voltage dividers for the cathode ray oscillograph.

2. An automatic 6-element oscillograph is used for current and pressure measurements. This oscillograph is equipped with a mirror to provide the initial sweep motion, and a motor which brings the recording paper up to speed before the mirror reaches the end of its travel.

3. A pressure recorder is used for measuring the pressures developed in the expulsion protective gap and recoil forces developed during its operation. The pressure record is automatically recorded by the 6-element oscillograph during the test.

4. A ground resistance meter.

5. A dark room which enables film to be developed and examined in less than 5 minutes after the measurement.

6. A portable 110-volt power supply for operating the equipment where no such supply is available.

The equipment described above is so versatile that the effect of all circuit conditions on recovery voltage can be determined.

Figure 9 shows both the cathode-ray oscillograph and magnetic oscillograms obtained during a staged 3-phase test on a 26.4-kv system utilizing a 75-ohm neutral ground. It may be noted that the expulsion gap on phase 3 opened the circuit ahead of phases 1 and 2. The expulsion gaps on phases 1 and 2 opened simultaneously on phase-to-phase current as this current was much greater than the ground current. Had the system neutral been solidly grounded, the two last to clear would have operated on ground current at their respective current zeros.

## Mountings

Proper mounting arrangements are vital to successful operation of expulsion gaps. The series gap must be controlled to prevent its becoming either too great or too small. Where the series gap becomes too small, a greater percentage of line voltage is applied continuously to the tubing, which results in corona tracking and damage to the fiber. The limits for the series gap setting are determined by 2 factors:

1. The minimum setting allowable is that which prevents excessive continuous voltage being applied to the tube, or an unnecessary number of operations.

2. The maximum setting is that beyond which protection will not be obtained for the insulators in parallel.

It is preferable to have the series gap setting as large as possible and still protect the insulation as it reduces the normal operating voltage on the fiber tube and is in the direction to keep the number of gap operations at a minimum. The ionized gases must be properly directed, to avoid flashovers due to their conductivity. Figure 10 shows the length of the flame path as a function of the power current through the flashover protector. Obviously the circuit voltage and the expulsion gap dimensions should enter in such a relation. However, the curve can be used to estimate the safe distance for objects in the direction of the flame having a different potential from that of the discharge gases. Sufficient clearance should be provided between the expulsion gap and the structure to which it is attached to assure that lightning flashovers will be confined within the expulsion gap.

Recoil forces must be considered when designing the mounting hardware. The magnitude of the recoil force is a function of the velocity and pressure of the discharge

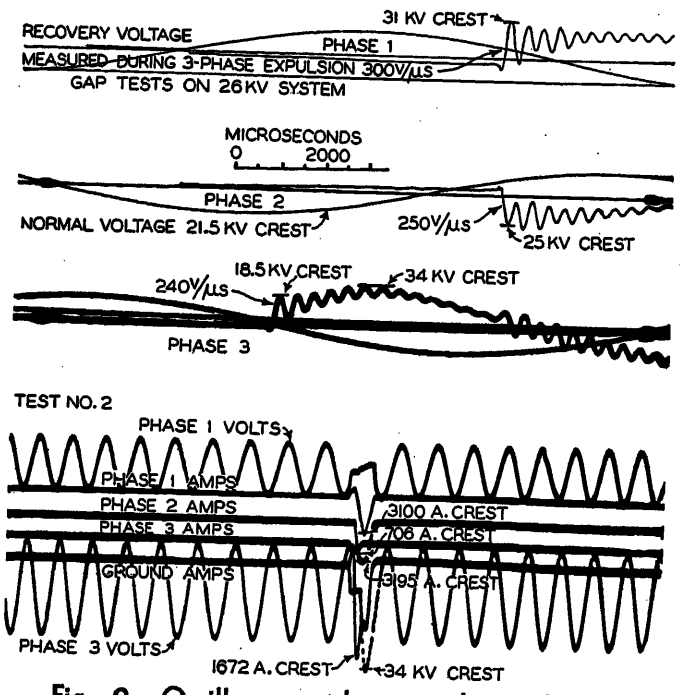

**Fig. 9. Oscillograms taken on the 3-element cathode-ray oscillograph and automatic magnetic oscillograph during staged tests on expulsion protective gap for a 26.4-kv system**

gases and the shape of the opening at the end of the expulsion gap. Tests have been made on flexible mountings which show that the recoil force is a function of the current and the design. The relation between these factors has been determined by an extensive series of tests and is taken into account in the finished designs. The pressure-time relation of the recoil force is of nearly the same shape as the current, although slightly lagging. While the recoil force may reach values in the order of 3,000 pounds, the time is so short that the expulsion gap and its mounting hardware does not move appreciably until the pressure has ceased. The acceleration imparted to the expulsion gap during this short period results in further movement and an oscillation whose frequency is determined by the mass of the expulsion-gap assembly and the rigidity of its mounting. The greater the mass of the assembly, the less the energy imparted by the discharge. The greater the rigidity of the mounting, the greater the stress in the mounting.

It is of utmost importance that the mounting hardware be designed to facilitate ease of installation. This results in a direct saving to the operator and broadens the field of application.

## Weathering

It is felt that insufficient time has elapsed to form any definite opinion as to the ultimate life expectancy of expulsion gaps. Past experience with plain fiber tubes for expulsion gaps as well as in other applications has indicated the real necessity of providing a weather resistant covering to avoid deterioration of the fiber and warpage.

While experience to date has shown the textolite-covered tubes to have excellent weathering characteristics, and to be free from warpage, organic materials cannot be expected to have a life comparable with inorganic materials such as porcelain. Periodic refinishing of the tubes with a weather-resistant paint, will increase the weather resistance, although examination of expulsion gaps from both service and accelerated life tests, have indicated that the textolite wrapping retains its dielectric and mechanical properties when subject to the weather under normal conditions, and that refinishing of tubes is not essential. There is a slight discoloration of the outer layer of the laminated paper after the original finish disappears. However, a careful checkup has shown this condition to have had no harmful effect on either the operating characteristics or life. The electrodes and all metal parts are of selected weather resisting alloys.

## Operating Experience With Expulsion Gaps

Operating experience where records have been obtained on expulsion protective gaps installed since 1933 is given in table I. It may be noted that they have been equally successful in overcoming the lightning outages for both low- and high- voltage systems. Care should be exercised, however, when interpreting the data regarding operations. The discharge indicator consists of a strip of soft copper bent across the open end of the tube. The escaping gases cause the strip to be moved from its position. Obviously this indicator does not count the actual number of operations. Usually the line is patrolled at intervals of from 1 to 2 weeks or only after lightning storms. Therefore a blown indicator can only be taken to mean that an operation has occurred since the last inspection of the line. Whether there has been one or more operations such as might occur with multiple lightning strokes will not be disclosed. It should be noted that every blown indicator does not necessarily mean a separate stroke to the line, as a severe lightning stroke may not only cause operation of all expulsion gaps on the structure nearest the point struck, but may cause operations on the adjacent structures as well. At present there is not sufficient data available to arrive at a factor which will permit determination of the number of strokes to the line in terms of indicator operations; however, it is expected that the number of strokes to the line will be somewhat less neglecting multiple strokes.

1. Gaps on every fourth structure.
2. Gaps on every third structure.
3. Gaps on every second structure.
4. Gaps on each circuit of structures equipped (double circuit lines). Multiplex connection neutral tube common to both circuits.

† The cause for these flashovers has been determined and remedied.
* Twelve operations due to improper relay settings.
** Double-circuit steel-tower line.
‡These records are incomplete.
#Operations for only one patrol of line.
§Part of tripouts due to towers being knocked down and other causes than lightning.

Field experience has indicated to date that the average number of times an expulsion gap will be called upon to operate will not cause sufficient erosion of the fiber tube to constitute a factor in its life. From table I the number of operations per year has been worked out for the 3 circuit voltages for which records are available: 13.8, 69, and 138 kv, for which the years elapsing between operations of a given expulsion gap are, respectively, 6.7, 5.12, and 9.75.

While the present data indicate that operations occur on the lower voltage circuits more frequently than on the higher voltage circuits, further experience may show otherwise. In general this appears logical as the flashover voltage is lower and less stroke current is required to cause operation.

The operating records which have been obtained over the past 5 years with many thousand expulsion protective gaps are in themselves proof that line tripouts and outages caused by lightning can be practically eliminated. Thus, expulsion gaps increase the reliability of the system, improve the system stability, and reduce maintenance by preventing damage to the line insulators.

# Empirical Method of Calculating Corona Loss From High-Voltage Transmission Lines

By JOSEPH S. CARROLL
ASSOCIATE AIEE

MABEL MACFERRAN ROCKWELL
MEMBER AIEE

## Synopsis

It is difficult to find a mathematical formula which will fully agree with observed data on corona loss under all conditions. Therefore, a purely empirical method of corona loss calculation has been developed, based on analysis and co-ordination of the experimental data which have been accumulated at Stanford University.

## Introduction

THERE IS great need for a method whereby the corona loss which will occur on a transmission line of any given description can be predetermined with a fair degree of accuracy. It is difficult to find a mathematical formula which will fully agree with observed data under all conditions. For this reason it has been thought desirable to develop a purely empirical method of corona loss calculation, based on analysis and co-ordination of the experimental data which have been accumulated at Stanford University over a number of years. These data are useful for such a purpose because they were obtained with considerable accuracy on sections of line erected out-of-doors in 3-phase configuration on actual insulator strings, and corresponding with present-day high voltage transmission practice in regard to the size, height, and spacing of the conductors.

The method developed is based on the experimental observation that the shape of the curve of corona loss versus voltage for cables of sizes used in high voltage transmission is virtually constant, and that the effect of variation in such factors as spacing, diameter, altitude, etc., is simply to shift this fundamental curve parallel to itself along the voltage axis. Having established the characteristic curve shape, the problem reduces to developing empirical rules for determining its location under any given set of conditions.

## Basic Data for Study

The results of the experimental work at Stanford University have been incorporated in a series of papers[1,2,3,4,5,6] which will be used as the basic material for the present study. The effect of incomplete removal of die grease was not at first fully appreciated, and puzzling inconsistencies resulted in some cases. Hence only certain curves of the references cited are suitable for use in the present analysis, and these with due qualification for the degree of cleanliness of the conductor surface. This matter is discussed in greater detail in appendix I.

The curves selected for use are assembled in figure 1, having been replotted to semilogarithmic co-ordinates from the original test points. It is readily seen that the relative positions of the curves, when considered with respect to conductor diameter, are somewhat inconsistent with one another. These apparent inconsistencies are largely due to differences in spacing, air density, and surface condition. It is the purpose of this paper to analyze the effect of these factors and properly co-ordinate the curves.

## Characteristic Shape of Corona Curve

The essential similarity in shape of the corona curves is apparent from figure 1. For calculations of ordinary accuracy any one of the curves (except that for the rope-lay cable) could be selected as typical with good results. However, close analysis shows divergencies which may possibly be of significance if very fine comparisons are being drawn or if the curves are to be extrapolated very far. Apparently the loss level at which the transition to the steeper slope occurs becomes higher as the diameter is increased. Apparently, also, the curves for the smooth segmental surface are slightly steeper than those for the stranded surface. In 2 cases the curves for stranded aluminum appear to be a little steeper than those for stranded copper, but this is believed to be largely a matter of experimental conditions. The curve for weathered stranded cable drops faster in the lower region, than does that for the same cable unweathered.

The curve for the rope-lay cable has a distinctive shape which should not be regarded as typical for any other cable. The corona characteristics of the rope-lay cable are notably poor.

For the convenience of the reader a few curves are assembled in figure 2 which are believed to be reasonably typical for various cases noted. For purposes of reproduction the numerical co-ordinates of several points on each curve are listed in table I. If any fine distinctions are to be drawn or comparisons made between the merits of different types of construction, however, the curves of figure 2 should by no means be accepted as basic, but the reader should go directly to figure 1 and use his own judgment as to what typical shape or shapes to select.

Turning to figure 3, the solid line represents the shape of a composite corona-loss curve for a cable $^1/_2$ inch to 2

A paper recommended for publication by the AIEE committee on power transmission and distribution. Manuscript submitted February 2, 1937; released for publication March 25, 1937.

inches in diameter, based on figure 2 but plotted in the more familiar rectangular co-ordinate form. The location with respect to the voltage scale is selected at random. If this curve is arbitrarily projected downward from a point $A$ corresponding to about 4 kw loss, it intercepts the voltage axis at a point $e_1$. The shape of this curve $e_1 AB$ then closely resembles that of the curve for a small highly polished wire ($^1/_4$ inch diameter or less), although the latter would of course be located farther to the left on the voltage axis. For the small polished wire, corona is of a fairly uniform character and begins at a definite voltage $e_1$ which in general is a function of the electrostatic gradient at the surface for a given impressed voltage, the nature and condition of the surface, and the air density. On the large cable, localized brushes of an unstable nature begin to occur at a relatively low voltage and cause the curve below point $A$ to diverge from the small-wire form. However, the upper part of the curve $AB$, corresponding to general corona, is the controlling element and fixes the location of the entire curve. Hence it is this upper portion or its projection $e_1$ on the voltage axis, which should be given consideration in analyzing the relative locations of various corona curves.

Analysis of many test curves for large cables shows that if the upper part $AB$ is projected to find $e_1$ the latter falls approximately at the voltage corresponding to one kw loss. This is a purely empirical observation of curve shape, but is very convenient for general use. Individual curves may deviate slightly from this general rule; but even so, the error resulting from such deviation is of second order magnitude. This is because in performing shifting operations $e_1$ is used merely as a basis for calculating the kilovolts shift corresponding to a certain percentage shift of the curve position. If the value of $e_1$ selected is, let us say, 10 per cent in error and the shift to be applied is 5 per cent, the curve after being shifted will be within one-half of one per cent of its correct position.

The curves plotted on semilogarithmic co-ordinates, figures 1 and 2, show a distinct "break" or increase of slope at about 2 to 9 kw loss. This break no doubt corresponds to the transition from the unstable brush pattern region to the region of general corona. The curves apparently follow the law $y = a^x$ fairly closely, with one or more changes in the value of $a$.

## Shift for Air Density

Air density is given by the expression

$$\delta = \frac{17.9\,b}{459 + t}$$

where $b$ is barometric pressure in inches of mercury, $t$ is temperature in degrees Fahrenheit. The denominator $459 + t$ represents absolute temperature.

With lowered density the air breaks down at a reduced gradient and $e_1$ is decreased, shifting curves to the left. Hegy and Dunlap[6] conducted experiments at Stanford University using number 2 B and S gauge copper wire in a tank which could be evacuated to simulate various barometric pressures. The curves for different pressures were found to be parallel, furnishing a striking demonstration of the constancy of curve shape. Owing to the small size of the wires there was virtually no brush-pattern region, but the wires went almost directly into regular corona. Hence it was easy to locate their intercepts on the voltage axis. These intercepts were found to be spaced in propor-

tion to a function somewhat under the first power of the pressure. Other tests have substantiated this conclusion.

The Hegy and Dunlap results also show that when the absolute temperature of the ambient air changes, producing an inverse change in the value of $\delta$, the intercepts follow the first power of $\delta$. However, studies made by Nuttall[7] indicate that when the cable temperature is higher than that of the ambient air, $\delta$ should be calculated on the basis of a temperature corresponding to the ambient plus $^2/_3$ the rise above ambient.

Although the Hegy and Dunlap tests were made on small-size conductor, they actually concern not so much the conductor itself as the mobility of the ions in the air around it. Therefore, the results should apply equally well to any conductor in full corona. Hence, if the upper or general-corona portion of a curve for large-size cable be projected onto the voltage axis, its intercept $e_1$ should vary with air density by a law similar to that demonstrated by Hegy and Dunlap for small-size conductor.

It will be convenient to reduce all the curves of figure 1 to terms of the normal barometric pressure at sea level (29.9 inches) and 76 degrees Fahrenheit, which makes $\delta = 1.00$. Since the tests were all made close to sea level the pressure changes involved are very small, and it will be sufficiently accurate to assume that the projected intercept $e_1$ varies as the first power of the pressure. As the intercept also varies inversely as the absolute temperature, this means that the intercept can be taken as varying in direct proportion to $\delta$.

In table II the air densities for each curve of figure 1 are computed, using in each case a temperature equal to the ambient plus $^2/_3$ the cable rise above ambient. These values of $\delta$ are reproduced in column 4 of table III. Column 5 of the latter table shows the kilovolts for one kw loss for each curve, which is taken as representing $e_1$. Then in column 6 the kilovolts for one kw loss is multiplied by $1.00/\delta$ to give a shifted position of $e_1$ for standard air density $\delta = 1.00$.

## Shift for Spacing

Curves (*f*) and (*g*), figure 1, are both for 1.49-inch copper conductor with stranded surface. The former is at 30-foot spacing, the latter at 22-foot. The curves appear quite parallel, with possibly a slight divergence at the higher losses. Column 6 of table III shows that the kilovolts for one kw loss on the 2 curves are respectively 307 and 295, after the shift to $\delta = 1.00$ has been applied. The curve for the smaller spacing is therefore to the left of that for the larger spacing. The reason for this is that with the smaller spacing the electrostatic capacitance between the wires is greater, and hence the concentration of stress at the conductor surface is greater with the same applied voltage. Since the amount of charging current is an index of the concentration of stress, we might expect the variation in charging current to be an inverse index of the variation in $e_1$.

The ratio of voltages, 30-foot spacing to 22-foot spacing, at the one-kw loss level is $307/295 = 1.04$. Charging currents at the 2 spacings, calculated by the method given in Pender's Handbook,[8] show an inverse ratio of 1.052 for the center conductor, and 1.037 for either outer conductor. These values agree with the actual observed values of charging current. Apparently the outer conductor charging current is the more accurate index of the variation in $e_1$.

Of course, the mere fact that the $e_1$ ratio checks the charging current ratio for one experimental point does not prove that the charging current is necessarily a correct index of $e_1$ for all other variations in spacing. It is merely the best hypothesis that is available in the light of present knowledge. It should be applied with caution, especially where the range covered is very different from that represented by the change from 22-foot to 30-foot spacing. Fortunately the curves in figure 1 are all at spacings of 20, 22, or 30 feet, and so in reducing them all to terms of a common spacing—say 22 feet—no correction need be applied greater than that of 1.04 already experimentally established for the change from 22 to 30 feet. For the small change from 20 to 22 feet an interpolation, direct or logarithmic, should be sufficiently accurate, giving in either case a correction factor of 1.01.

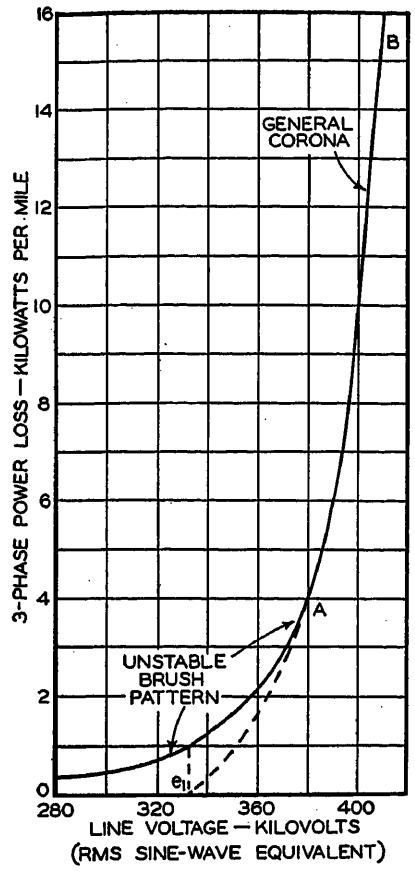

**Fig. 3. Composite corona curve for cables 1/2 to 2 inches diameter based on typical curves of figure 2, converted to rectangular-co-ordinate form**

If the transition from one spacing to another occurs with a conductor size different from the 1.49-inch diameter applicable to curves (*f*) and (*g*), the correction factor would not be expected to be affected much, as a study of capacitance tables indicates that the ratio of charging currents for two different spacings varies only slightly with conductor diameter in the range 1/2 to 2 inches.

In column 7 of table III are listed the factors for correcting each curve to terms of 22-foot spacing. Applying these factors to the kilovolts for one kw at $\delta = 1.00$ given in column 6, there are obtained the values of column 8. The latter represent the kilovolts at one kw for $\delta = 1.00$, 22-foot spacing. Comparing these figures with the corresponding points from the original curves, column 5, the difference (column 9) represents the net kilovolt shift to cover the corrections to standard air density and spacing. Since it has been established that changes in air density and spacing produce virtually parallel shifts of the curves, then the kilovolts shift at any other loss level will be the same as the kilovolts shift at the one-kw loss level. For instance, column 10 of table III gives the kilovolts for 4-kw loss on the original curves of figure 1, and column 11 gives the same figures with the kilovolt shift of column 9 added or subtracted as the case may be. Thus column 11 represents the kilovolts for 4 kw loss at 22-foot spacing, $\delta = 1.00$.

## Shift for Weathering

Curves (*e*) and (*i*) of figure 1 show the effect of weathering on a new 1.125-inch copper stranded cable after it had been dragged in loose gravel on level ground. In the original record (figure 5, Carroll and Cozzens[3]) the intermediate stages are also shown. It is there seen that the dragging moved the corona curve very sharply to the left, compared to its position just after the gasoline, soap and water wash of the new cable; but that almost at once, the curve started to move back to the right due to weathering. After 4 months it had returned approximately to its original location. In fact, in figure 5 of Carroll and Cozzens (and also in figure 1 of the present paper, where the initial and final curves are reproduced), the final curve lies actually to the right of the initial curve. However, the temperature was higher, and the barometric pressure lower, at the time the final curve was taken; hence the air density was appreciably less. When the curves are both placed on an equal footing of standard air density, as is done in table III, column 8, it is found that they become virtually coincident at the one-kw point. Observation showed that after the 4-month weathering period no further appreciable change occurred.

The weathered and unweathered curves differ in shape in the lower or brush-pattern region. Hence their true relationship is shown more clearly by focussing attention on a higher level of loss—say 4 kw, where the general corona region is entered and the 2 curves become nearly parallel. At this level column 11 of table III shows that under standard air density conditions the curve (*i*) for dragged and weathered conductor lies at 291 kv and the curve (*e*) for new conductor at 296 kv. This represents a correction factor of 291/296 = 0.983 to be applied to the kilovolts for 4-kw loss of any curve taken just after a gasoline, soap and water wash of the degree of thoroughness which prevailed in the experiments for the Carroll and Cozzens paper,[3] to represent the effect of dragging and weathering as described in the same paper.

It may be said at this point that despite the divergence in shape, the use of the kilovolts for one kw loss to represent $e_1$ in applying the spacing and air-density shifts to the curve for dragged and weathered cable introduced no ap-

* Estimated

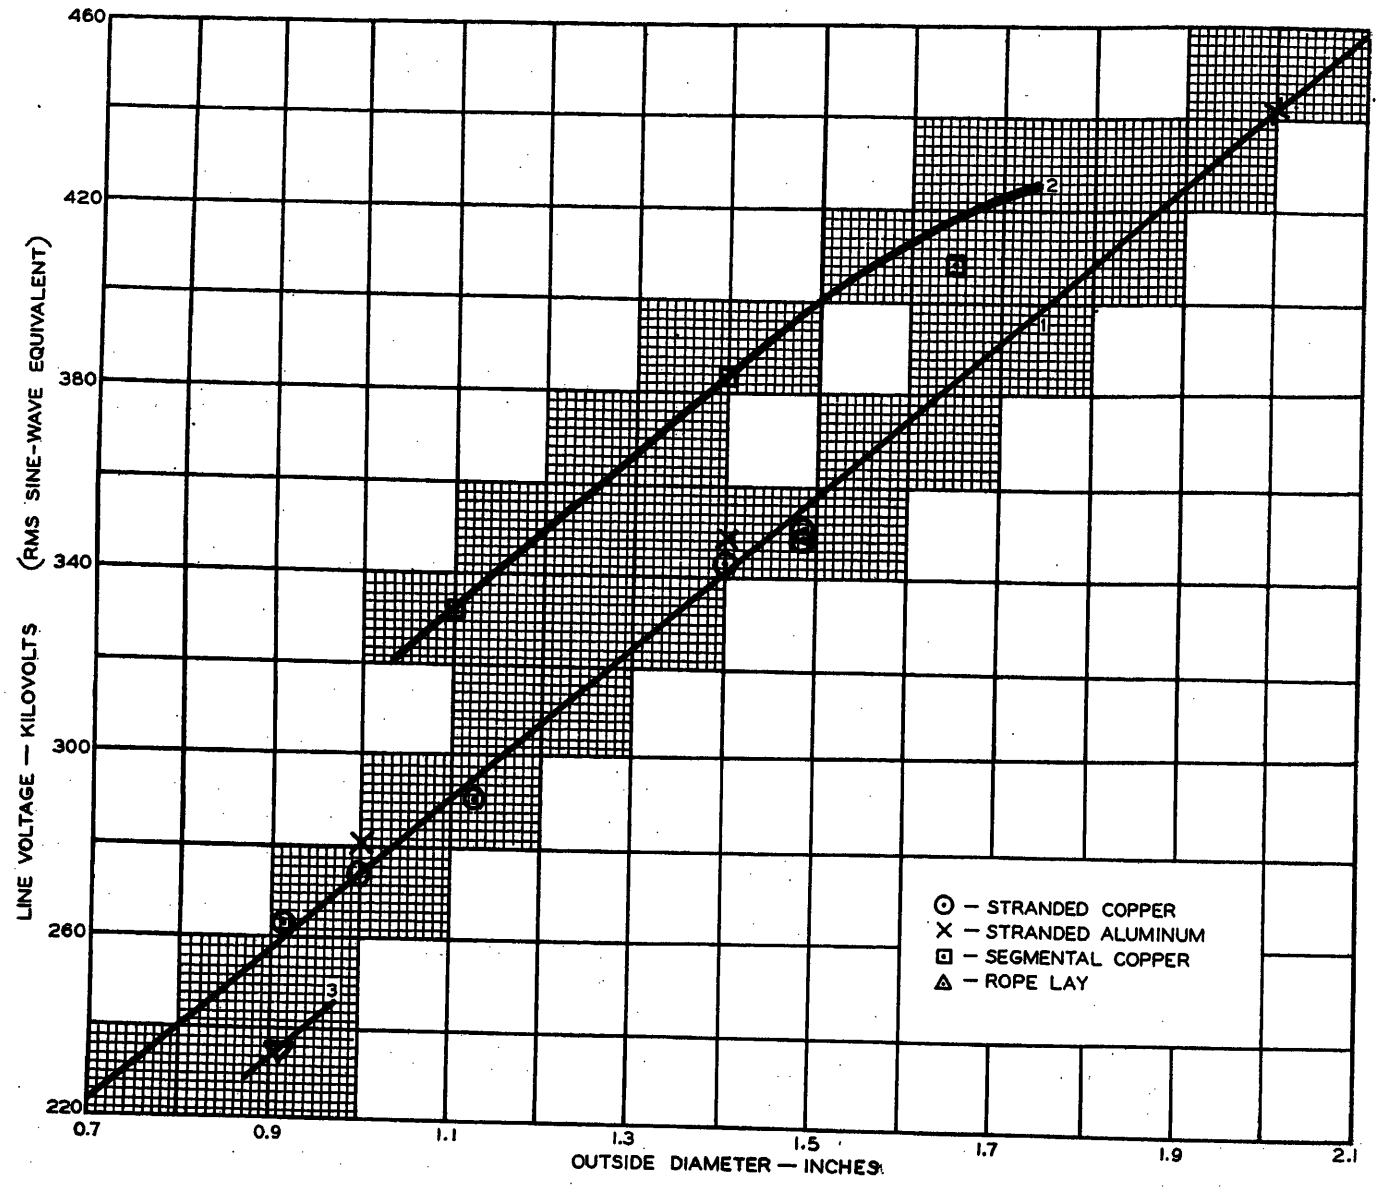

**Fig. 4. Co-ordination curves**

Kilovolts for 4-kw 3-phase corona loss per mile. Dragged and weathered conductor; 22-foot flat spacing; sea level; air density = 1.00; 60 cycles per second; Curve 1—Concentric strand; Curve 2—Smooth segmental; Curve 3—Rope lay

preciable error, because in that case the relation of a weathered to an unweathered curve was not under analysis. The one-kw point might have been a few kilovolts in error in representing the true $e_1$ of the dragged and weathered curve, but this would have a negligible effect on the amount of the shift obtained by applying the correction factors for air density and spacing.

It has been stated that the correction factor for weathering as determined from curves (*e*) and (*i*) applies only when the initial condition is similar to that just after a gasoline, soap and water wash of about the degree of thoroughness which prevailed in the experiments for the Carroll and Cozzens paper.[3] This covers only curves (*e*) to (*i*), figure 1. Curves (*j*) to (*n*) inclusive, which were taken from the Carroll, Cozzens, and Blakeslee paper[4] and the Carroll and Simmons paper,[5] represent a somewhat more thorough type of cleaning than do the curves of the earlier papers, and hence may be expected to lie relatively a little farther to the right than do the earlier curves. Hence it would not be reasonable to expect the weathering process to be able to return the cable, after dragging, to a condition having a curve as close to the initial one, as was true in the earlier cases. A weathering factor of 0.92 might be estimated for the later curves (*j*) to (*n*). Conversely, the very early curves (*a*) to (*d*), taken from figure 11 of Carroll, Brown, and Dinapoli[1] were not quite so well cleaned as the Carroll and Cozzens curves, and so would have a weathering factor of perhaps about 0.99.

It is recognized that the estimates of weathering factor, other than that for the curves of the Carroll and Cozzens paper where a definite experimental tie exists, are more or less empirical. However, they are believed to be quite

reasonable, because when the kilovolts for 4-kw loss under standard conditions given in column 11 of table III are corrected for weathering according to the factors derived above and the resulting voltages (column 13) are plotted as functions of conductor diameter, the points fall in such a way as to define a set of smooth curves (see figure 4).

## Co-ordination Curves

The curves of figure 4 represent the kilovolts for 4-kw loss for a group of conductors of various diameters and structures all reduced, so far as is possible in the light of present knowledge, to terms of the same air density, conductor spacing, handling, and weathering. As such they constitute a co-ordination of existing data and furnish a convenient means of interpolation for determining losses on conductors not covered by published corona-loss curves.

The points fall naturally into 2 groups—one for the smooth segmental cable (type *C* of the Carroll, Cozzens, and Blakeslee paper[4]) and the other for stranded cable. In addition there is a lone point for rope-lay cable which falls far below the curve for concentric strand. This rope-lay cable has an extremely irregular surface, as it consists of 7 large strands twisted together, each of these large strands being composed of 7 wires, 0.101 inch in diameter. Hence it is not surprising that its corona characteristics should be notably poor.

At the other extreme of surface smoothness lies the segmental cable, the 3 points for which lie well above the curve for stranded cable and appear to define a curve of their own. The authors have ventured to apply a curve shape for this cable which misses the point for 1.65 inch diameter, because the sample of the latter which was tested was of foreign manufacture and had been handled much more than the other cables.

That the curve for smooth segmental cable actually belongs above that for stranded cable is brought out especially well by the 3 points for 1.4 inch diameter. These were all taken from the curves of the Carroll, Cozzens, and Blakeslee group and hence the cleaning conditions were similar.

The transition from rope-lay to smooth segmental cable represents a variation between the extremes of very large strand size and zero strand size. Between these extremes lie the points for the ordinary concentrically stranded cable; and as already noted, these points all fall very close to a representative straight line. This is despite the fact that the strand sizes in the individual cables vary considerably. However, it is probable that the ratio of strand size to diameter is the really significant factor, because this is a measure of the degree of irregularity of the cable. In this respect the cables classed as "stranded" varied from a ratio of 0.065 to a ratio of 0.11. Attempts to find any reliable evidence of variation in loss with strand size ratio within this range were unavailing, and it is apparent that the differences, if they exist, are so small as to be masked by slight differences in surface cleanliness, etc.

The points for stranded aluminum might possibly be thought to define a curve of slightly different location than that for stranded copper; but it is believed that this is merely a matter of slight variations in experimental conditions and that no true distinction exists. Many attempts to establish a difference between the characteristics of the copper and aluminum surfaces have led to the conclusion that there is none. (See for example, Weidlein's paper.[2])

## Effect of Conductor Height

Nothing has been said as yet of the effect of conductor height above the ground. This can be neglected in most cases, because the height of the experimental lines at Stanford corresponded fairly well with general transmission-line practice. The minimum clearance to the earth was 30 feet, and the maximum 46 feet. No difference in the corona on the upper and lower parts of the catenary could be observed. A mean conductor height of 35 feet gave a

* Dragged and weathered; all other curves immediately after gasoline, soap and water wash

calculated value of charging current which checked well with observed values. In these calculations the ground plane was assumed to be at the surface of the earth, which appears to be true electrostatically for the normal balanced condition even where it is not true from the standpoint of return flow of ground fault currents. Thus the element of variation of ground plane level below the earth's surface is eliminated from corona calculations, and hence different transmission lines will not vary greatly in mean conductor height. Any correction that is to be applied will be quite small, as it enters logarithmically from the inverse charging-current calculation.

## Effect of Frequency

The curves of figure 1 were all made at 60 cycles. For other frequencies there will be no horizontal shift of the curves, but all ordinates should be multiplied by a correction factor. For frequencies not far different from 60 cycles this factor is given closely enough by $f/60$.

## Effect of Atmospheric Conditions

Humidity will have practically no effect on the corona loss if the conductor is absolutely clean. When the cable is dirty or greasy, however, increase in humidity tends to increase the loss.

A rainstorm increases the corona loss temporarily, due to the formation of brushes from the drops of water which adhere to the surface of the conductor. The same is true of a deposit of fog droplets or dew upon the surface.

Abundance of rain may be expected to accelerate the weathering process somewhat, especially if grease removal is involved.

## Summary—Determination of Corona Loss Under Any Given Conditions

To determine the corona loss to be expected from any conductor under any set of conditions, the procedure is as follows:

1. Read from figure 4 the root-mean-square kilovolts corresponding to 4-kw 3-phase loss per mile for the conductor in question. If the ratio of strand size to diameter is much above 0.11, interpolate a new curve between that for "concentric strand" and that for "rope lay."

2. Figure 4 represents the ultimate condition of a cable dragged over crushed rock in the manner described in the Carroll and Cozzens paper[3] and subsequently weathered for several months. If any departure from this condition is anticipated an appropriate correction should be applied to the kilovolts for 4-kw loss, as follows:

(*a*). It does not matter much whether the cable was originally clean or greasy, except that in the latter case it may take longer for the condition of figure 4 to be attained.

(*b*). If the cable is dragged very severely over jagged rocks which actually abrade the surface, it can never be expected to return to the condition represented by figure 4.

(*c*). If the cable is installed with no dragging at all the weathering process should gradually return it, even if it was originally greasy, nearly to the condition of a new clean cable. See (*d*). Much progress beyond this point seems unlikely.

(*d*). For a new cable thoroughly cleaned by the technique of the Carroll, Cozzens, and Blakeslee paper[4] the kilovolts for 4-kw loss will exceed the values of figure 4 by about 8 per cent (representing division by the factor 0.92).

3. Plot the kilovolts for 4-kw loss, corrected as above, on semilogarithmic co-ordinates representing loss vertically and voltage horizontally.

4. Draw through the point so plotted, a corona curve of appropriate shape. As a short cut this may be based on the "typical curves" of figure 2, though if any fine distinctions between different types of cable are to be drawn, it is recommended that the reader use his own judgment based directly on the experimental curves of figure 1. If a new clean cable is to be considered, the slope of the lower portion of the curve should be made a little less steep than is indicated by figure 2.

5. After the curve is drawn, it should be shifted at the one-kw loss point to correct for air density and conductor spacing. For the spacing shift use the following table:

22 to 30 feet—multiply kilovolts by 1.04
22 to 20 feet—divide kilovolts bo 1.01

Interpolate logarithmically. For extrapolations of any great range, correct in inverse proportion to the charging current on the outer wire. This method of extrapolation has not been completely verified, however, and should be used with caution.

For the air density shift, since the values of figure 4 are based on a density of 1.00, multiply the kilovolts for one kw by the anticipated air density, using a temperature equal to the ambient plus $^2/_3$ the cable rise. This will be sufficiently accurate where the change in barometric pressure is not very great. If a wide range is to be covered, as by going to a high altitude, the shift should probably be made more nearly in proportion to the $^2/_3$ power of the barometric pressure. Until experimental work can be carried out at high altitudes it is impossible to be completely certain of this rule, as it now rests largely on laboratory evidence.

A convenient way to perform the shift at the one-kw point is to compute the total net shift and determine the new kilovolts for one kw. Then make a movable voltage scale and slide it sidewise until this new voltage is directly under the one-kw loss point of the curve. Securing the movable scale in this location it is then possible to read off the loss at any desired voltage, as for example 230 kv. This method is especially helpful if a number of different conditions of altitude, temperature, etc., are to be investigated for a given line.

A numerical example of the loss calculation is worked out in appendix II.

## Conclusions

1. Experimental evidence shows that the shape of the curve of corona loss versus voltage for cables of sizes used in high voltage transmission is virtually constant

2. The major effect of variations in diameter, spacing, altitude, temperature, surface structure, and surface condition is to shift the

characteristic curve parallel to itself along the voltage axis

3. The amount of the shift which will result from any given change in conditions can be determined empirically on the basis of experimental data. Thus the characteristic curve can be placed in a location corresponding to any given set of conditions and the loss for any voltage determined

4. By this means corona-loss calculations for large conductors are placed on a foundation of carefully co-ordinated experimental evidence.

## Appendix I—Selection of Curves From References

The paper by Carroll, Brown, and Dinapoli[1] is the earliest of the references to be considered, and in this paper the importance of thorough cleaning was just beginning to be understood. Though some washing of conductors was carried on, it is now known that by later-day standards this cleaning was imperfect in many cases, leaving some die grease between the strands which kept oozing out, collecting dust, and giving erratic results. It is believed, however, that the curves of figure 11 may be accepted for comparison with later data, having been taken immediately after a fairly good gasoline, soap and water wash. Curve 1 of figure 11 is to be rejected, however, because the conductor had surface irregularities which resulted in abnormally poor corona characteristics.

The paper by Weidlein,[2] next in order of publication, contains no curves taken with conductor sizes and spacings used in high-voltage transmission lines, but is important in pointing out the effect of surface conditions and in showing that "corona losses from copper and aluminum conductors are the same after weathering."

In the next paper, that by Carroll and Cozzens,[3] the washing methods were fairly good. Curves 2, 4, 5, and 7 of figure 7, namely, those which are marked "washed," may be accepted for use in the present analysis. Those marked "new" cannot be used due to the grease present on the surfaces. Figure 5 of this reference is also very important because it shows clearly the relation between corona loss on a washed new cable and that to be expected after the cable has been dragged on crushed rock and then erected and allowed to weather for several months. Figures 4 and 6 are not particularly pertinent in the present study as they have to do with cable which has been buffed, scratch-brushed, etc.

In the paper by Carroll, Cozzens, and Blakeslee,[4] improvement was made in cleaning methods, as it had been learned that all grease must be removed from between the strands and inside the cable to avoid any traces of oozing afterward. All the earlier curves of this paper are summarized in figures 12 and 13. Figure 12 is for the cables after gasoline, soap and water wash; figure 13, after a clear water wash. The latter gets the cables a little cleaner for the moment but the results do not last any length of time at all, so that comparative measurements are most difficult. The gasoline, soap and water wash, however, leaves the conductor surface in a quite stable condition which is satisfactory for comparisons and which is modified only very gradually as weathering occurs. Furthermore, it is important to stick to the "gasoline, soap and water wash" curves to preserve the important tie-in between loss under this condition and that occurring after dragging and weathering, given by figure 5 of Carroll and Cozzens.

In figure 12 of Carroll, Cozzens, and Blakeslee, curves 5 and 9 are reproductions of curves 4 and 7, figure 7, Carroll and Cozzens. Curve 1 is to be eliminated due to incomplete grease removal and difficulty in obtaining smooth stranding with the multiple I-beam construction. Curve 2 is also eliminated because it was calculated from single-phase measurements and because the cleaning is believed to have been incomplete. Curve 7 is eliminated because it was made on a sample of cable produced before manufacturing methods had been perfected, resulting in surface irregularities. This leaves curves 3, 4, 6, and 8 of figure 12 as the only ones furnishing data pertinent to the present study.

In the Carroll and Simmons paper[5] the washing methods were of the best and curve 1 of figure 2 can well be utilized in the present study.

## Appendix II—Numerical Example

### Problem

Determine the corona loss to be expected on a 50-mile section of line located at 1,250 feet elevation, temperature 100 degrees Fahrenheit. The line is to be built of 0.95-inch concentric-strand cable and operated at 230 kv. The conductors will be arranged in a flat horizontal configuration with 25-foot spacing. They will be rendered reasonably free from grease at the factory.

### Solution

From figure 4, curve 1, the kilovolts for 4 kw = 267.

In the absence of any information to the contrary it is a fair assumption that the dragging and weathering conditions will be similar to those applying in figure 4 (except for the first few months when residual grease may be present to increase the loss). Hence the kilovolts for 4 kw read from figure 4 can be used directly with no correction applied.

Curve 1 of figure 2 may be used as a short cut to indicate the typical curve shape. The zero of the voltage scale then represents 267 kv. The curve passes through one-kw loss at minus 40 kv, which would then represent 267 − 40 = 227 kv. This can be taken as the approximate value of $e_1$.

The spacing is to be changed from 22 feet in figure 4, to 25 feet in the actual case. A change from 22 feet to 30 feet, or 8/22, gives a correction factor of 1.04. The change contemplated is from 22 feet to 25 feet, or 3/22.

By logarithmic interpolation the new correction factor would be:

$$c_s = 1.00 + \left[\frac{\log (3/22)}{\log (8/22)} \times (1.04 - 1.00)\right] = 1.00 + \left[\frac{\log 3}{\log 8} \times 0.04\right] = 1.00 + \left[\frac{0.4771}{0.9031} \times 0.04\right] = 1.02$$

The barometric pressure at 1,250 feet is approximately 28.5 inches of mercury. Hence

$$\delta = \frac{17.9 \times 28.5}{459 + 100} = 0.913$$

Hence net correction factor for $e_1$ is $0.913 \times 1.02 = 0.931$

Corrected $e_1 = 0.931 \times 227 = 211$ kv at one kw.

If curve 1 of figure 2 is considered to be so located that its one-kw loss is at the new $e_1$, or 211 kv, then −40 on the scale represents 211 kv. 230 kv will be 19 kv farther to the right or at (−40 + 19) = −21 kv. The loss for this point on the scale is seen to be about 1.9 kw per mile. Hence the loss for the 50-mile section of line will be $50 \times 1.9 = 95$ kw.

# Properties of Saturants for Paper-Insulated Cables

By G. M. L. SOMMERMAN
MEMBER AIEE

## Synopsis

The results of tests made on 9 viscous mineral oils of various types and on mixtures of these oils with 8 resins are presented. The physical and electrical properties, stability to oxidation, and stability to gaseous ionization are correlated with the viscosity index and chemical composition of the oils and resins. The catalytic effects of metals on oil oxidation are studied. Gaseous ionization in insulation voids is found to exert a physical pressure and to accelerate saturant oxidation.

## Introduction

IT is generally agreed that the selection of saturating compounds for impregnated paper insulation is a problem of great importance and one which requires considerable investigation. This problem has been reviewed in the past by Riley and Scott[1] and others. The saturants must meet a number of requirements concerning their physical properties such as viscosity, set point, coefficient of expansion, and surface tension. These are particularly important for materials used in solid-type, paper-insulated cables (the type commonly used at 66 kv and lower voltages). Here, correct physical properties are necessary to minimize migration of the saturant and consequent void formation caused by the combined action of gravity heads and cable operating temperature cycles. In addition, the saturants must meet certain requirements concerning electrical and stability properties, the most important of which are the following:

1. A reasonably low power factor.
2. A high oxidation stability (as measured by power factor change) so that the power factors of cables may be uniform notwithstanding unavoidable chances for oxidation in manufacturing operations, and so that possible exposure of the cable insulation to oxygen will not result in greatly increased power factor.
3. A low susceptibility to contamination (as affecting the power factor) so that possible exposure of the saturant to impurities both before and after it is absorbed by the paper will not result in greatly increased power factor.
4. A high stability to gaseous ionization (resistance to wax formation and gas evolution) caused by electrical stress in voids which may form in the insulation with use so that the amount of gaseous ionization will not increase cumulatively.

It is sometimes stated that it is better to expend effort in reducing the possibilities of oxidation and contamination than to mitigate them in other ways. Higher impregnating tank vacuums, inert gas flushing, and improved technique in both manufacturing and installing cables are steps in this direction. The users of cables, however, have obtained considerable evidence that the power factors of the most carefully made cables increase with time, even when the cables are stored. It is therefore still considered advisable to choose saturants which are resistant to oxidation and contamination, provided other properties are not sacrificed.

Cable saturants usually consist of mineral oils and mixtures of these oils with resinous materials. Materials of these classes have recently been considerably improved in certain respects. In this paper are presented the results of an extended research in which both the older and more recently developed materials have been investigated to determine their suitability as saturants for solid-type, paper-insulated cables. Much of it is also applicable to impregnated paper and insulating oils in general.

The general procedure followed in this investigation was to subject various prospective materials to a series of chemical, physical, electrical, and stability tests in order to determine how well they meet the requirements. The advantages of this procedure are several: (1) a great many materials may be investigated at comparatively small expense, leaving only the most promising materials to be tried out on the larger scale of fabricating test lengths of cable and subjecting them to load cycle life-tests; (2) small scale tests are subject to closer control than large scale tests; (3) the exact points of strength or weakness of a material are indicated and not merely the fact that it is good or poor; (4) the physical, electrical, and stability properties may be correlated with fundamental chemical properties. This last information can be used to indicate directions in which to look for better materials.

## Experimental Method

Measurements of power factor and dielectric constant were made on the materials at 60 cycles by means of a modified Schering bridge. The detector circuit of the bridge consisted of a 4-stage resistance-capacity coupled amplifier, 60-cycle band-pass filter, and an ordinary copper-oxide voltmeter which was not affected by mechanical vibrations. Magnetic pick-up was eliminated by connecting the amplifier directly to the detector terminals of the bridge, the entire detector circuit being shielded at guard potential. The power factor sensitivity was 0.00001 with 2,000 volts applied.

The electrical properties of the saturants were measured at 25, 45, 65, and 85 degrees centigrade at a stress of 15 volts per mil. The test cell was of nickel and glass construction, of the type described by Balsbaugh, Kenney,

A paper recommended for publication by the AIEE committee on research. Manuscript submitted February 23, 1937; released for publication March 23, 1937.

and Herzenberg,[2] but of larger dimensions so that the air capacity was 89 micromicrofarads.

The electrical properties of cable paper impregnated with the saturants were also measured at 25, 45, 65, and 85 degrees centigrade. The test cell pictured in figure 1 was used, the method of preparing the samples being as follows. Several sheets of paper were placed between the disk electrodes and subjected to a mechanical pressure of 15 pounds per square inch by means of the springs in order to ensure good contact between paper and electrodes. The paper was dried at 110 degrees centigrade and 1 millimeter mercury absolute pressure for several hours and the saturant was simultaneously degassed under the same conditions. The saturant was then admitted to the cell and allowed to impregnate the paper for 2 hours. After this period the specimen was cooled to 85 degrees centigrade and an inert gas was admitted until one-half atmospheric pressure was attained. With this procedure the moisture content of the impregnated paper was less than 0.2 per cent when measured by the ASTM method *D*95-24 using xylol. Variations in moisture content below 0.2 per cent were found to have no measurable effects on the power factor of the impregnated paper. That the procedure yielded a thorough impregnation was shown by the fact that the ionization factor (increase in power factor on raising the stress from 25 to 125 volts per mil at room temperature) was less than 0.00003.

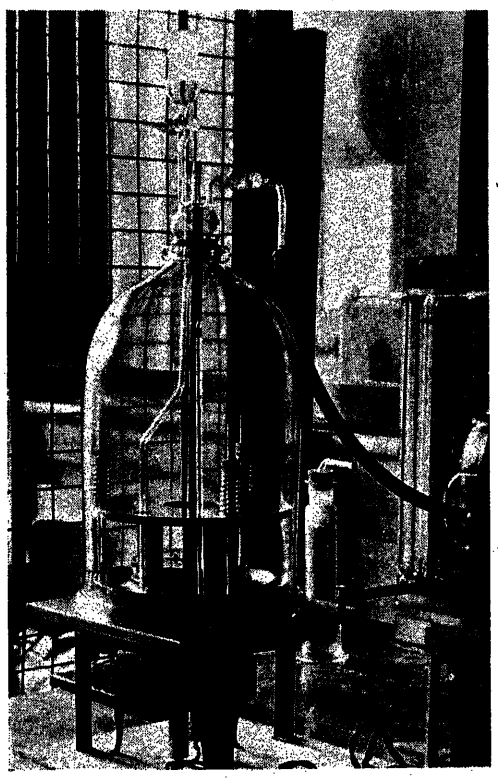

**Fig. 1. Cell for testing impregnated paper**

The relative oxidation stabilities of the saturants were determined by means of aging tests. Porcelain beakers containing samples of the materials were placed in an oven held at 120 degrees centigrade. The beakers were provided with loose fitting covers which kept dust out of the samples, but which did not prevent free access of air. The samples were removed at intervals for electrical measurements. This was accomplished with a minimum disturbance to the sample by immersing the measuring cell in the beaker, cooling them to 85 degrees centigrade, and placing them in a temperature-controlled box. After testing, the beaker and cell were removed from the box and heated to 120 degrees centigrade, the cell then removed, and the beaker placed in the oven for further aging. Oxidation tests made at various temperatures indicated that the rate of oxidation increased by 7 per cent per degree centigrade. The aging temperature was therefore maintained to within 0.5 degree centigrade of 120 degrees centigrade in order to minimize errors in oxidation stability results. Also, it was found that the rate of aging depended on the amount of the sample in the beaker, i.e., on the surface-to-volume ratio. A sample with a surface-to-volume ratio of 0.182 centimeter$^{-1}$ aged 1.60 times as rapidly as one with a ratio of 0.066 centimeter$^{-1}$. (This may mean that the rate of removal of dissolved oxygen by combination with the oil was comparable with the rate of diffusion and convection of the oxygen through the oil, resulting in a lower concentration of dissolved oxygen in the lower portion of the sample.) By close control of aging temperature and surface-to-volume ratio (at 0.066 centimeter$^{-1}$), it was possible to duplicate beaker oxidation test results to within 3 or 4 per cent.

The stability of the saturants to gaseous ionization was determined by applying an electric stress of 85 volts per per mil to saturated paper sheets in the cell shown in figure 1. In the preparation of the sheets, holes were punched in some of them and connecting slits cut between the holes and the edges of one of the sheets, so that artificial voids of known size were created in the sample after drainage of the excess saturant. (This scheme is similar to that developed at the Detroit Edison laboratory.) The cell was evacuated and a certain amount of inert gas was admitted so that the voids became filled with this gas. Carbon dioxide at 20 centimeters mercury absolute pressure was used in most of the tests, as this gas is extensively employed in flushing cables prior to saturation. The gas in the voids was ionized by the electric stress, the ionization factor of the sample being 0.04. After 96 hours exposure to ionization the sheets were removed and examined for wax formation. This was facilitated by extracting the saturant from the sheets and dyeing some of them as described by Robinson.[3]

## Materials Investigated

Results obtained for 9 mineral oils and 8 resins are presented in this paper. Descriptions of these materials and data concerning their chemical composition are given below.

### The Oils

The oils are the most viscous cylinder stocks made for commercial use by a number of different refiners. They were selected so that the principal fields of crude supply and types of refining procedures are represented. See table I.

In order to obtain information concerning the composition of the oils, various methods of analysis were used. One method was that of viscosity index developed by Dean and Davis.[4] In this method, an extreme Pennsylvania-type (paraffin base) oil having a relatively flat viscosity-temperature curve is assigned a viscosity index of 100, while an extreme California-type (asphalt base) oil having a relatively steep viscosity-temperature curve is assigned a viscosity index of 0. The viscosity indices of the 9 oils were calculated from their respective viscosity-temperature curves, and are included in table I.

**Table I—Description of Mineral Oils**

| Oil | Viscosity Index | Proportions of Basic Constituents | | |
|---|---|---|---|---|
| | | Paraffinic | Naphthenic | Residual |
| *O*-1 | −1 | 0 | 70 | 30 |
| *O*-2 | 4 | 0 | 65 | 35 |
| *O*-3 | 65 | 35 | 30 | 35 |
| *O*-4 | 84 | 55 | 35 | 10 |
| *O*-5 | 90 | 60 | 30 | 10 |
| *O*-6 | 96 | 55 | 35 | 10 |
| *O*-7 | 96 | 65 | 30 | 5 |
| *O*-8 | 100 | 65 | 30 | 5 |
| *O*-9 | 104 | 85 | 10 | 5 |

*O*-1 to *O*-3 Gulf Coast and East Texas crudes
*O*-4 to *O*-9 Midcontinent and Pennsylvania crudes
*O*-1 to *O*-4 Acid refined
*O*-5 to *O*-9 Solvent, fuller's earth or aluminum chloride refined

Further information on the composition of the oils was obtained by subjecting samples to selective solvent extraction processes. With the processes used, it was possible to separate an oil into 3 classes of constituents: (1) paraffinic, (2) naphthenic, and (3) residual. (These terms, commonly used in petroleum technology, will be defined on the basis of molecular structure in the discussion.) In this way the relative proportions of the basic constituents in the oils given in table I were obtained. It is seen that the oils of high viscosity index are rich in paraffinic constituents; these oils are hereafter called paraffinic oils. The oils of low viscosity index are rich in naphthenic constituents; they are hereafter called naphthenic oils.

**Table II—Description of Resins**

| Resin | Color | Acid Number | Saponification Number | Oxidized Resin Content |
|---|---|---|---|---|
| *R*-1 | Black | | | Large |
| *R*-2 | Red | 155 | 164 | Medium |
| *R*-3 | Yellow | 189 | 193 | Small |
| *R*-4 | Yellow | 174 | 185 | Small |
| *R*-5 | White | 186 | 186 | None |
| *R*-6 | Red | 15 | | Medium |
| *R*-7 | Yellow | 12 | | Small |
| *R*-8 | Yellow | 87 | 93 | Small |

### The Resins

A tabulation of the resins and their descriptive and chemical properties is given in table II. The resins *R*-1, *R*-2, *R*-3 are various grades of commercial wood rosin containing appreciable proportions of oxidized constituents (oxyabietic acids, aldehydes, ketones) and of nearly neutral oils. Resin *R*-4 was obtained by treating *R*-2 with solvents which removed most of the oxidized constituents and oils, while *R*-5 was obtained from *R*-4 by a further treatment which yielded a white crystalline form of pure abietic acid. By causing rosin to react with alcohols under special conditions, the resin esters *R*-6 and *R*-7 of low acid number were obtained. Resin *R*-8 was produced by a polymerizing reaction which also removed a large proportion of oxidized constituents.

## Solubility of Resins in Oils

When a resin is mixed with heated oil, a certain amount may fail to dissolve. Part of the insoluble matter settles to the bottom of the mixing container as a sludge, while part remains suspended in the oil. Data are given in table III. Resins *R*-1, *R*-2, *R*-6, which contain large percentages of oxidized constituents (table II) are highest in insoluble matter. Oils having a high content of certain types of residual constituents, such as *O*-3, dissolve much of the oxidized resin, while oils which are low in these constituents, such as the paraffinic oil *O*-9 or the naphthenic oil *O*-2, dissolve little of the oxidized resin.

The resins *R*-3, *R*-4, *R*-5, *R*-7, *R*-8 are practically entirely soluble in all the oils. When some of these oil-resin mixtures are allowed to stand at room temperature over a period of weeks, however, a gradual crystallizing out of some of the resin occurs. This behavior has also been observed by Kirch and Riebel.[5] It indicates that a certain amount of impurities is necessary in the resins in order that they may stay in solution in the oils. In the present work it was found that the optimum purity of the resin depends on the oil used. For example, resin *R*-4 is of greater than optimum purity for use in highly paraffinic oils *O*-7, *O*-8, *O*-9, as it crystallizes out when mixed with them, but this same resin mixed with oils containing more naphthenic or residual constituents, such as *O*-1, *O*-2, *O*-3, stays in solution perfectly, even when cooled to −10 degrees centigrade. *R*-5 is of greater than optimum purity for all the oils.

When oil-resin mixtures are oxidized, many of them form a resinous sludge. This is disadvantageous mainly in cable manufacturing as the impregnating tanks and pipe lines may become coated with sludge, and also the entrainment of suspended sludge on the outer layers of the cable insulation may hinder impregnation. The laboratory aging tests indicated that the sludge formation was large in mixtures made with resins which originally contained much oxidized material. Mixtures made with the purer forms of resin sludged somewhat when the oils used were predominantly paraffinic, but did not sludge in the other oils.

## Physical Properties

The principal requirements concerning the physical properties of saturants for solid-type cables are the follow-

ing. The surface tension must be fairly high to enable the saturant to be drawn into and held by the paper capillaries. The viscosity at the impregnating temperature (105 to 115 degrees centigrade) must be fairly low in order to obtain a thorough and economical impregnation. Throughout the temperature range in which cables may be installed or operated (−10 degrees to 80 degrees centigrade) the viscosity must be high to minimize saturant migration and, in case of injury to the lead sheath, bleeding of the saturant, yet the saturant must possess sufficient lubricating value to enable the cable to be bent. The coefficient of expansion should be low in order to minimize void formation caused by expansion and contraction of the saturant arising from temperature changes in service.

Data on the physical properties of the oils and oil-resin mixtures are given below.

## Viscosity

The viscosities of the oils at 100 degrees Fahrenheit are from 1,800 to 6,000 Saybolt seconds, and at 210 degrees Fahrenheit are from 100 to 180 Saybolt seconds. While discussing viscosity it is valuable to introduce the term *viscosity ratio*, which may be defined as the ratio of the viscosity at 100 degrees Fahrenheit to that at 210 degrees Fahrenheit. For oils of a given viscosity at 210 degrees Fahrenheit, the *viscosity ratio* is related to the viscosity index. Thus, for an oil of 140 Saybolt seconds viscosity at 210 degrees Fahrenheit, and viscosity index $\chi$, the *viscosity ratio* is $15 + 0.22\,(100\text{-}\chi)$.

From the viscosity requirements it follows that the viscosity-temperature curve of an ideal saturant for solid-type cables should exhibit a uniformly high value from −10 degrees centigrade to 85 degrees centigrade and then drop rapidly to a low value above 100 degrees centigrade. Unfortunately, no saturant having this characteristic has been found. The best compromise seems to be to select a saturant whose viscosity is fairly low at 110 degrees centigrade and which rises rapidly with decrease in temperature, but not so rapidly as to destroy the lubricating value at −10 degrees centigrade. Highly viscous saturants possessing *viscosity ratios* between 30 and 40 have been found very satisfactory.

**Table III—Percentage of Resin Insoluble in Oil**

| Oil | Resin R-1 | R-2 | R-3 | R-4 | R-5 | R-6 | R-7 | R-8 |
|---|---|---|---|---|---|---|---|---|
| O-2 | 6 | | | 0 | 0 | | | 0 |
| O-3 | 2 | | | 0 | 0 | | | |
| O-4 | 10 | 4 | 0 | 0 | 0 | 5 | 0 | 0 |
| O-9 | 7 | | | 0.3 | 0 | 8 | 0.3 | 0 |

The addition of resin to oil changes the viscosity characteristics as shown in figure 2. The effect is greater if the polymerized resin *R*-8 is used. It is seen that the addition of resin not only raises the viscosity, but also the *viscosity ratio*. This is due to the fact that the *viscosity ratio* of the resin itself is extremely high, about 10.[8] This effect of resin additions is advantageous if the oil alone does not possess a high *viscosity ratio*, as it leads to greatly reduced migration of the compound in service, without requiring a much longer impregnation period.

## Pour Point

The pour points of the oils are all below 0 degree centigrade, in some cases as low as −12 degrees centigrade. The oils do not set even at these temperatures because they are dewaxed. The addition of 15 per cent resin raises the pour point about 5 degrees centigrade. However, mixtures of resins with the most viscous oils possess sufficient lubricating value at −10 degrees centigrade for cable bending requirements.

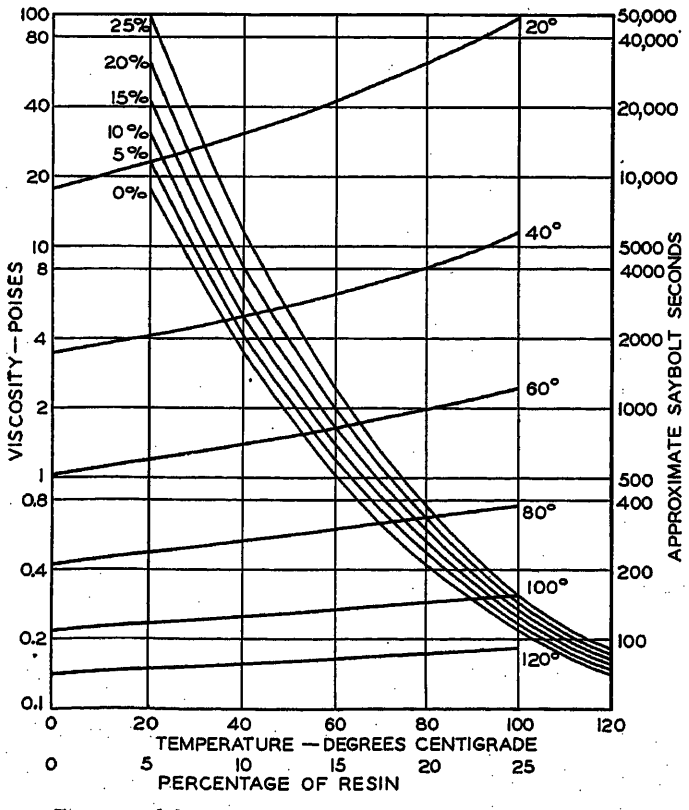

**Fig. 2. Variation of viscosity with temperature and viscosity with percentage of resin for mixtures of resin and oil O–4**

**Table IV—Specific Gravity and Coefficient of Expansion of Oils**

| Viscosity Index | Specific Gravity $\rho$ (at 25 Deg C) | Coefficient of Expansion $-(1/\rho)(d\rho/dT)$ (per Degree C) |
|---|---|---|
| High | 0.88 to 0.90 | 0.00070 |
| Medium | 0.90 to 0.92 | 0.00067 |
| Low | 0.92 to 0.94 | 0.00064 |

## Specific Gravity and Coefficient of Expansion

Oils of low viscosity index have higher specific gravities and lower expansion coefficients than oils of high viscosity

index as shown in table IV. The addition of 15 per cent resin to the oils increases the specific gravities and reduces the expansion coefficients 1 or 2 per cent.

### Surface Tension

The values for the different saturants at 110 degrees centigrade are from 28.5 to 32.5 dynes per centimeter. The variations in surface tension with temperature, type of oil, and addition of resin are similar to the corresponding variations in specific gravity.

## Electrical Properties

### Dielectric Constant

For well-refined mineral oils, the variations in dielectric constant $\epsilon$ with temperature and with type of oil are accounted for by the corresponding variations in specific gravity.[6] This may be seen by comparing the dielectric constant curves for oils *O*-2, *O*-4, and *O*-8 in figure 3 with the specific gravity data in table IV. The addition of resin to oil increased the dielectric constant as is also shown in figure 3. Part of this increase is caused by the increase in specific gravity imparted by the resin, and the remainder by orientation of the polar resin molecules. The data indicate that the dipole moments of the ester *R*-7 and the polymerized resin *R*-8 are larger than the moment of pure abietic acid *R*-5.

The dielectric constants of the materials increased slightly (less than 5 per cent) during the aging tests. The changes in dielectric constants were roughly proportional to the changes in power factor which are discussed later.

### Power Factor

The power factor-temperature curves of the oils are plotted in figure 4. Although there are large percentage differences in the values for the different oils, all the values

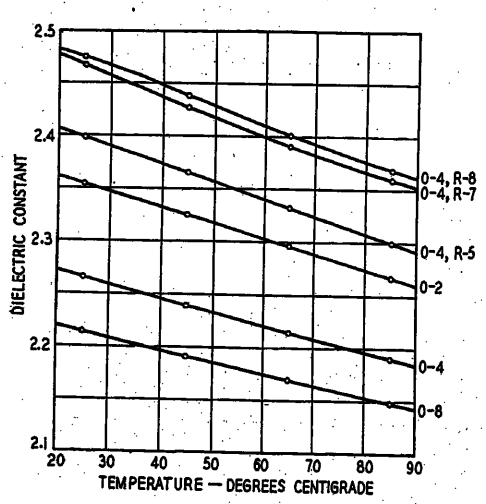

**Fig. 3. Dielectric constant-temperature curves of oils and oil-resin mixtures (15 per cent resin)**

are less than 0.004 at 85 degrees centigrade which is satisfactory for cable manufacturing purposes. These curves show that the relative increases in power factor per degree centigrade are about 6 per cent.

For a given oil, there is an approximately inverse relationship between the power factor and the viscosity, as has been shown by Kirch and Riebel[5] and Whitehead.[7] Compare figure 4 with figure 2. For this reason oils of high *viscosity ratio* often possess relatively steep power factor-temperature curves. It will be shown later, however, that relative steepness of the curve of the saturant has little effect on the curve of the saturated paper unless the absolute value of the saturant power factor at 85 degrees centigrade is high.

The effect of adding resins to oil on the power factor is shown in figure 5. It will be seen that if the resin contains oxidized constituents (*R*-2, *R*-6) or volatile constituents (*R*-3, *R*-7), the power factor of the resulting oil mixture is greater than that of the oil alone. This increase in power factor is especially large for oils which dissolve much of the oxidized resin as shown by the curve for *O*-3, *R*-2. If the resin has been largely freed of impurities (*R*-4, *R*-5), the power factor of the oil mixture is about the same as that of the oil alone. (Low power factors for purified resins in oils have also been reported by Kirch and Riebel.[5]) In some cases the addition of resin actually reduces the power factor, as may be seen by comparing the curves for oil *O*-9 with and without *R*-4. This may be due

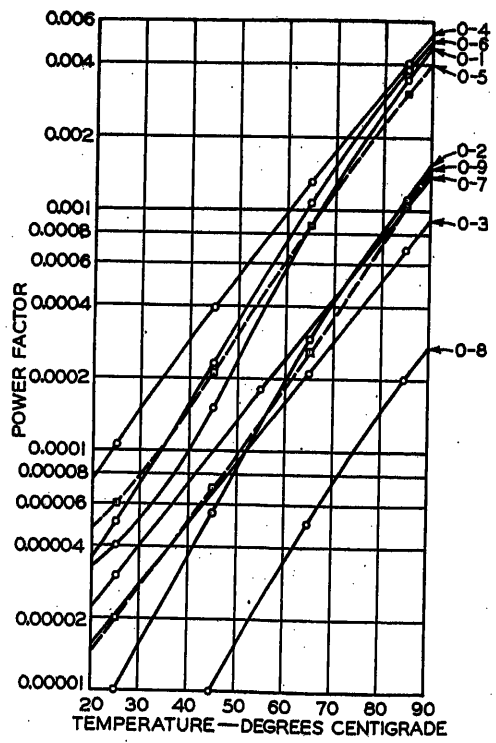

**Fig. 4. Power factor-temperature curves of oils**

in part to the fact that some volatile constituents are driven off in the mixing operation, and in part to the reduction of the mobilities of conducting ions existing in the oil caused by the increased viscosity imparted by the resin. The power factors of oil-resin mixtures bear no relation to the acid numbers.

### Conductivity

Values of a-c conductivity are related to the 60-cycle power factor thus, $\lambda_{ac} = 3.33 \times 10^{-11} \epsilon \delta$. Whitehead[7]

has noted that the ratio of a-c conductivity to long-time d-c (final) conductivity may be high for new oils, but is low for deteriorated oils. This has been confirmed in the present work, in which d-c measurements were made at 85 degrees centigrade on the saturants. Typical data are given in table V. Included in the table is the conductivity at one minute after voltage application, a measurement widely used in commercial insulation tests. This value lies between the a-c and final values, but at 85 degrees centigrade it is generally nearer the final value. The ratios of a-c to one-minute conductivity are from 1.2 to 3 for the new oils, but are usually only a few per cent greater than one for aged oils. For oils aged in contact with many metals, the ratios are also little more than one, but for oils aged with lead, the ratios are higher, often about 2. If the oil contains moisture, the ratio is high; if the oil is then aged

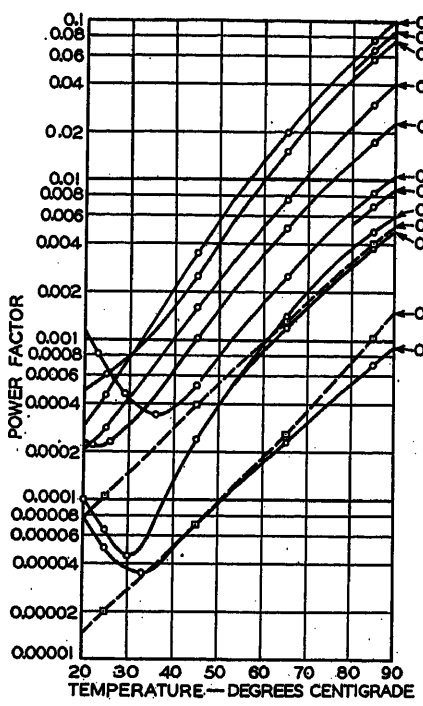

**Fig. 5. Power factor-temperature curves of oil-resin mixtures (15 per cent resin)**

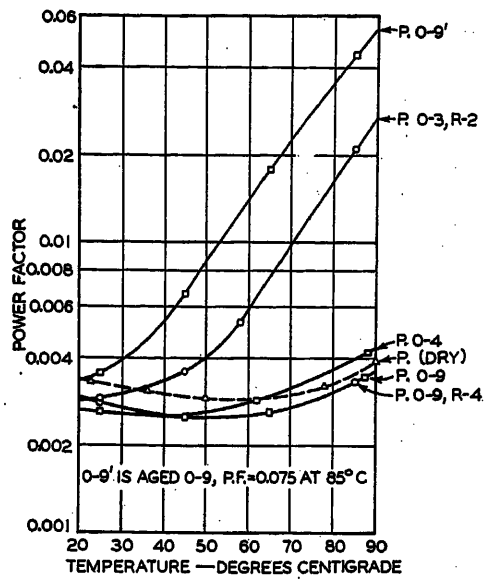

slightly, the a-c conductivity decreases while the final conductivity increases. The addition of resin to oil increases the final conductivity, even when it decreases the a-c conductivity.

### Power Factor of Impregnated Paper

The effect of variations in the saturant properties on the power factor of impregnated paper was investigated. Power factor-temperature curves of a high density paper impregnated with various saturants were determined, some of which are shown in figure 6. The typically flat power factor-temperature curve of the dried, unimpregnated paper is also shown. It is seen that if the saturant has a low power factor (either a straight oil or a mixture of an oil and a purified resin), the curve for the saturated paper is similar to that for the dried paper. If the saturant has a high power factor (either a straight deteriorated oil or a mixture of an oil and an impure resin), the curve for the saturated paper partakes more of the nature of the curve for the saturant, exhibiting high power factors at the higher temperatures.

The conditions necessary for the existence of a functional relationship between the power factor of a given type of paper impregnated with various saturants and the saturant power factors were deduced from Whitehead's work on dielectric loss.[7] These conditions are that the saturant

**Fig. 6. Power factor-temperature curves of saturated paper**

dielectric constants do not differ greatly and that *the saturants have equal viscosities*. For these conditions, values of saturant power factor $\delta_s$ and power factor of saturated paper $\delta_{sp}$ were read from the power factor-temperature curves. A family of curves of $\delta_{sp}$ versus $\delta_s$ was drawn, each curve corresponding to a certain saturant viscosity $\eta$, as shown in figure 7. It is apparent that $\delta_{sp}$ is not greatly affected by variations in $\delta_s$ below 0.003 at 85 degrees centigrade.

The curves in figure 7 are approximately of the form $\delta_{sp} = A + (B + C\eta)\delta_s$, where $A$, $B$, and $C$ are parameters. $A$ depends on the electrical properties of the paper, and $B$ and $C$ depend on the oil-to-paper ratio.

## Oxidation Stability

From the data presented in figures 4, 5, and 6, it is apparent that the power factor of impregnated paper is sat-

**Table V—Conductivities of Saturants at 85 Degrees Centigrade**

| Saturant | $\lambda_{ac}$ | $\lambda_1$ | $\lambda_f$ | $\lambda_{ac}/\lambda_1$ | $\lambda_{ac}/\lambda_f$ |
|---|---|---|---|---|---|
| O-9 New | 7.5 | 4.2 | 2.3 | 1.78 | 3.26 |
| Aged 50 hours | 6.8 | 4.1 | 3.0 | 1.66 | 2.27 |
| New + 10 per cent R-4 | 5.8 | 3.5 | 2.6 | 1.66 | 2.23 |
| O-4 New | 29.6 | 21.0 | 16.3 | 1.41 | 1.82 |
| Aged 100 hours | 117 | 115 | 112 | 1.02 | 1.05 |
| Aged 100 hours (lead) | 208 | 127 | 119 | 1.64 | 1.75 |

$\lambda_{ac}$ = a-c conductivity; $\lambda_1$ = one minute conductivity, $\lambda_f$ = final conductivity
Unit = $10^{-14}$ mho per centimeter

isfactory throughout the cable operating temperature range if the saturant power factor is satisfactory at 85 degrees centigrade. Consequently, in studying the oxidation stability of cable saturants, it is important to follow the changes in power factor at 85 degrees centigrade.

The oxidation test data are presented in the form of power factor versus time-of-aging curves. In these curves a slow rate of rise of power factor with time of aging indicates a high stability to oxidation.

The aging curves obtained for the 9 oils are shown in figure 8. Oils *O*-1 and *O*-3 (of the light acid refined type), which contain appreciable amounts of certain types of residual constituents, are seen to be poorest in oxidation stability. Oils *O*-5, *O*-6, *O*-7, *O*-8, and *O*-9 are more stable, the stability being proportional to the degree of refining. Most of these more stable oils were refined by recently developed processes which yield highly paraffinic oils (see table I). It should be pointed out, however, that naphthenic oil *O*-2 and paraffinic oil *O*-4, refined by similar acid processes, have nearly the same stability. This suggests that naphthenic oils are not inherently less resistant to oxidation, and that their stability might be improved if better methods of refining them were used.

The oils which are poorest in oxidation stability also have the greatest solvent powers for impurities, and are therefore most susceptible to contamination.

The effect of adding various resins to oil *O*-4 on the oxidation stability is shown in figure 9. The power factor of the oil mixed with the impure resin *R*-2, although higher than that of the oil initially, changes but little with aging, and is much less than that of the oil alone after aging. The power factor of the oil mixed with the purified resin *R*-4 increases but slowly from its low initial value with aging. Such stabilization of the oil is also produced by additions of the resin esters *R*-6 and *R*-7 and the polymerized resin *R*-8, although to a lesser extent.

In the series of resins *R*-2, *R*-4, and *R*-5, the stabilizing value decreases somewhat with increased purification. The partially purified resin *R*-4, however, is nearly as effective as the unpurified resin *R*-2, for part of the apparent effectiveness of *R*-2 is due to the fact that some of the originally dissolved oxidized constituents sludge out during aging.

The oxidation stabilities of all types of mineral oils is improved by the addition of resins, as may be seen by comparing the aging curves for the mixtures of *R*-4 with the oils, figure 10, with the curves for the oils alone, figure 8. Each oil-resin mixture has a useful life which is about 5 times that of the corresponding oil alone.

There are often large and varying departures from linearity in the power factor versus time-of-aging curves shown in figures 8, 9, and 10. If, therefore, the power factors before and after 100 hours of aging are analyzed alone, as is often done in evaluating the oxidation stability of liquid dielectrics, false conclusions may be drawn.

1,100 cubic centimeter samples of oil aged at 65 degrees centigrade for 176 days. Surface area of metal strips = 105 square centimeters

## Catalysts

When the oils were aged in contact with copper, lead, and steel strips, the catalytic effect of the metals accelerated the rate of power factor change for most of the oils, as may be seen by comparing the aging curves in figure 11 with those in figure 8. The rates of deterioration of the 2 oils of lowest viscosity index, *O*-1 and *O*-2, were not accelerated, but slightly retarded. This result was carefully checked.

The presence of metals in oil-resin mixtures did not change the rate of deterioration. This may be due to the fact that the dissolved oxygen was consumed near the surface of these mixtures. It at least indicates that the resins do not readily form harmful compounds with metals.

A study was also made of the relative catalytic powers of metals on the deterioration of oil. In these tests the aging temperature was reduced to 65 degrees centigrade so that the ordinary chemical combination of dissolved oxygen with the body of the oil would be reduced to a low value, and so that most of the oxidation would take place at the

metal surfaces. The differences in catalytic effects of the metals were thus accentuated. It was found that the power factor versus time-of-aging curves were nearly linear and so only the initial and final values are given in table VI. It is of interest to note that the catalytic effect of copper is 21 times that of tin. The presence of dissimilar metals in contact causes little or no additional effect through battery action, because the absolute conductivities of the oils are very low.

## Effects of Gaseous Ionization

In the tests for the determination of stability to gaseous ionization, the applied electric stress produced highly energized gaseous ions in the voids. These ions, on striking the saturated paper at the ends of the voids, caused chemical changes in the materials. The changes were chiefly polymerization and condensation of the saturant molecules, leading to the formation of the familiar "*X*" or wax and to the evolution of gas. Chemical changes involving gas molecules also occurred under certain conditions.

### Wax Formation and Gas Evolution

Some of the wax patterns obtained in the tests are shown in figure 12. It is apparent that there is a large variation in the tendencies of the oils to form wax. A correlation was found between the wax formation, expressed in arbitrary units, and the viscosity index of the oils. This is indicated in figure 13. The correlation is nearly as close as the probable error in estimating wax formation, some 10 per cent, even though the oils studied are of different types and methods of refinement. Oils rich in naphthenic or residual constituents are much more resistant to gaseous ionization than the highly paraffinic oils. Figure 13 indicates also that the addition of resin to oils increases the stability to ion bombardment, at least for the more paraffinic oils.

The data plotted in figure 13 are the amounts of wax at

the ends of the artificial voids. For most of the compounds this was the only wax formed. But for oils of very low viscosity index, both with and without resin, wax was also present on the surfaces of the paper sheets at other places. If the total wax were considered, the wax formation versus viscosity index curves would be U-shaped, the values at very low viscosity indices being too ill-defined to be indicated.

No gas evolution was detectable in the ionization tests performed with hydrogen gas present. A small amount

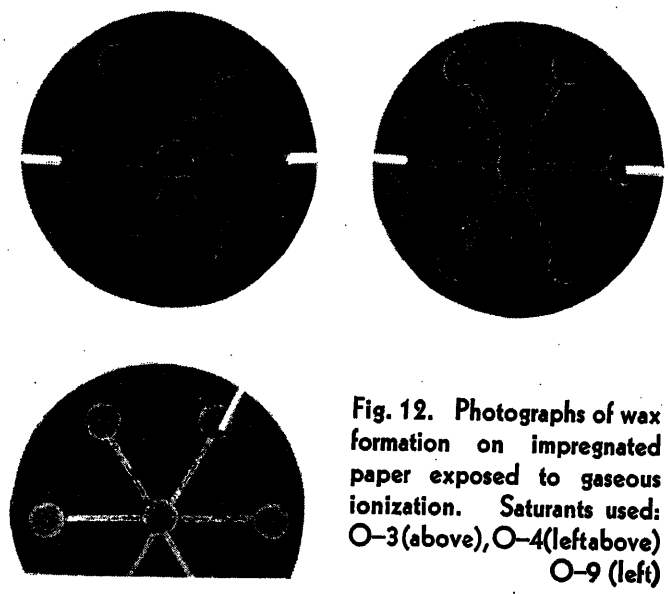

Fig. 12. Photographs of wax formation on impregnated paper exposed to gaseous ionization. Saturants used: O–3 (above), O–4 (leftabove) O–9 (left)

was observed when $CO_2$ was used, but this was independent of the saturant. There is evidence that this gas evolution was due to the breaking down of $CO_2$ into CO and O in the regions of very high stress at the electrode edges. Part of the evolved oxygen entered into the wax formation at the electrode edges, but not in the artificial voids. No significant changes in power factor of the saturated paper occurred in the ionization tests carried out under $CO_2$ or hydrogen.

The results of preliminary tests in which saturants in a glass cell under high vacuum were subjected to electric stress indicate that the gas evolution varies with the viscosity index of the oil and the addition of resin in a manner similar to that depicted by the curves in figure 13, except that the range of variation is much less.

### Combined Ionization and Oxidation

When gaseous ionization tests were carried out under reduced air pressure instead of under an inert gas, it was found that the gas pressure in the cell decreased with time. This took place at room temperature only when voltage was applied and ionization occurred. This indicates that the glow discharge facilitates the combination of oxygen with cable saturants by what might be termed an "electrocatalytic" action. This is substantiated by the fact that the wax formed in these tests was much greater in amount and darker in color than that formed in the tests with inert gases. Also, the power factor of the impregnated sheets increased markedly during the tests under reduced air pressure, although this effect was much smaller for resin-containing saturants than for straight oils. The data are given in table VII.

### Gaseous Ionization Pressure

Gaseous ionization in insulation voids, in addition to promoting chemical changes, was observed to exert a physical pressure on the insulation surrounding the voids. One manifestation of this pressure is that much of the wax formed in the oil films on the paper surfaces at the ends of the voids was forced to the edges of the voids where the ionization was less severe. This can be observed in the wax patterns in figure 12. Another manifestation, which was most pronounced after very long periods of ionization, is that some wax was forced through the paper sheets in the direction of the field. It is likely that ionization pressure was responsible for the effects observed by Proos,[8] namely, that the displacement of saturants away from regions of high stress in cables was greater with simultaneous application of voltage and heat cycles than with application of heat cycles alone. It is also likely that the ionization pressure, by forcing the saturant from the paper, facilitates the formation of the microscopic carbonized paths through paper which have been found by Robinson[3] to be sufficient to initiate a "treeing" mechanism resulting in eventual breakdown of the cable insulation. In order that the tendency of the ionization pressure to force the saturant through the paper may be resisted without the application of hydrostatic pressure, as in the oil-filled cable, it is necessary that the paper be dense and that the saturant be high in viscosity and surface tension, and strongly adsorbed by cellulose.

## Discussion

The observation made in the ionization stability tests that the gas evolution from oils of low viscosity index is less than that from oils of high viscosity index may be explained by the fact that the former oils contain more residual constituents than the latter (see table I). The residual constituents of the oils include aromatic compounds. Compounds of this type, although simpler in character, were found to evolve less gas than simple paraffinic compounds in the early tests carried out at the Detroit Edison laboratory.[9] It has also been recently shown by Nederbragt[10] that additions of small amounts of aromatic compounds to mineral oils are sufficient to lower the gas evolution considerably. The explanation usually given for this is that much of the gas, chiefly hydrogen, which is evolved instantaneously is reabsorbed by the double bonds in the molecules of the aromatic compounds. Since the molecules of the resins discussed in this paper also contain 2 double bonds, the reduction in gas evolution by resin additions to oils is also explained.

The majority of the molecules comprising the paraffinic and the naphthenic constituents of oils do not contain double bonds. It is possible that, on exposure to ionization, it is easier for hydrogen atoms to be detached from the open chain groups which form a large part of the structure

of the molecules of the paraffinic constituents than from the ring groups which predominate in the molecules of the naphthenic constituents. This would be a basis for explaining why the oils of very high viscosity index polymerize to form wax more readily than the oils of lower viscosity index, and why petrolatum, the molecules of which consist almost entirely of open chain groups, waxes even more readily than highly paraffinic oils.

The effect of resin additions in reducing wax formation is more difficult to explain. It is known from lubrication theory that a very small percentage of polar material added to a mineral oil can, by becoming adsorbed on metal surfaces, give a preferred orientation to the majority of oil molecules (non-polar) in the vicinity of the surfaces. Resin molecules, being polar, undoubedly become adsorbed by paper. This probably causes a similar preferred orientation of the oil molecules in the vicinity of paper-oil interfaces. The direction of this orientation may be such that those portions of the oil molecules which are exposed to the gaseous ion impacts are less vulnerable to their effects.

A comparison of the oxidation stability curves presented in figures 8 and 11 with the composition of the oils given in table I indicates that most of the paraffinic and naphthenic constituents and some of the residual constituents are stable to oxidation. The aromatic constituents are probably stable. The unstable residual constituents, which are usually dark in color, also render oil more susceptible to contamination.

The solvent refining processes commonly used in America in the production of lubricating oils of high viscosity index remove naphthenic and residual constituents which are stable to oxidation in addition to those which are unstable. These processes improve oxidation stability at the expense of greatly reducing the stability to gaseous ionization. In refining cable impregnating oils, processes should be used which remove only those constituents which are unstable to oxidation.

Oil oxidation products are hydrophilic, as shown by the spreading of aged oil on water. Many of them are acidic. They cause the high power factor of aged oils by dissociating to form conducting ions. Since all these properties are possessed by the oxidation products, it is sometimes concluded that all hydrophilic substances, especially acids, also have the property of causing high power factor, and that such substances should not be added to insulating oils, at least not in large amounts. It has been shown in this paper, however, that certain purified resins, which are hydrophilic and acidic in character, are important exceptions to this hypothesis, for their presence in oils has little or no effect on the power factor. Moreover, the addition of these resins has been shown to be beneficial from the standpoint of stability.

The basic parent substance of the resins is abietic acid, which has the empirical formula, $C_{20}H_{30}O_2$. This substance is far less reactive than most organic acids, partly because of its high molecular weight and partly because of the way in which the acid group is attached to the molecule. This is why purified resin does not esterify readily or form harmful compounds (soaps) with metals, and why it has a low ionic dissociation constant (low power factor) in oil solutions.

There are several indications in the oxidation stability tests of oil-resin mixtures (for example, the data given in table VII) that the stabilizing influence of the resin is not due to a reduction in oxygen absorption, but to the fact that the resin oxidation products dissociate to form fewer conducting ions than do oil oxidation products. The data in figure 9, which show that crystalline abietic acid is nearly as effective as commercial resins in stabilizing oil power factor, indicates that most of the oxygen absorbed by the resins is taken up by the double bonds of the resin molecules.

## Correlation With Cable Life

It may be well to consider a few results of cable life studies in connection with the results presented in this paper. Life tests made by Whitehead[11] and more recently by Race,[12] although under oil-filled cable conditions, showed that, other things being equal, specimens saturated with naphthenic oils had longer lives than those made with paraffinic oils. The saturants used in the solid-type cables having good service records have been found to be very stable to gaseous ionization. Resin-containing cables have established good service records, although the older types of resin-containing cables did not appear to advantage in some of the load cycle life tests made in the past. The writer believes this was mainly due to the exaggeration of the higher dielectric loss of these older cables under the accelerated test conditions which led to thermal instability, a fault of the test rather than of the cables. With an improved, less accelerated life testing technique, Halperin and Betzer[13] have lately found that

the use of resin in cables of recent manufacture has resulted in increased stability and life.

## Conclusions

The results of the investigation may be summarized as follows:

1. Much valuable information can be obtained by subjecting cable saturants to various simplified tests and by correlating the results with viscosity index and chemical composition.

2. The addition of resin to mineral oils reduces migration of the saturant in cable operation without correspondingly increasing the time required for impregnation.

3. Oil-resin mixtures are not high in power factor unless the resin contains oxidized or volatile constituents.

4. The power factor of paper impregnated with mixtures of oils and properly purified resins is approximately the same as that of straight oil saturated paper.

5. For a given type of paper and for saturants of the same viscosity, the power factor of impregnated paper is a function of the saturant power factor.

6. Both naphthenic oils (low viscosity index) and paraffinic oils (high viscosity index) may possess good oxidation stability. The most stable oils now available are paraffinic.

7. The catalytic effect of metals on oil oxidation is greater for paraffinic oils than for nonparaffinic oils. The catalytic effect of copper is much greater than that of lead which in turn is much greater than that of tin.

8. The addition of resin to all types of mineral oils improves the oxidation stability as measured by power factor change.

9. Highly paraffinic oils are less stable to gaseous ionization than oils low in paraffinic constituents.

10. The addition of resin to oils containing some paraffinic constituents increases their stability to gaseous ionization.

11. Gaseous ionization in insulation voids exerts a pressure which tends to force the saturant from the paper.

12. Gaseous ionization in the presence of oxygen exerts an "electrocatalytic" effect on the oxidation of cable saturants. This results in a copious, dark wax formation and an increase in power factor which is less for resin-containing saturants than for straight oils.

# Distribution Lightning Arrester Performance Data

THE intelligent application of lightning arresters requires a knowledge of their performance characteristics under conditions which are likely to be encountered in service. Data have been presented relating to the impulse characteristics of insulation both as used on lines and in transformers. In order to know what protection may be secured with certainty in service, data are also required concerning the rates of voltage rise to be expected on distribution type arresters and the current encountered as a result of natural lightning. These data are being obtained, in some measure at least, through the use of impulse current measuring devices in series with arresters in service. Very little satisfactory information is available, however, with respect to the actual rates of potential rise, in fact most of such information is based on deduction rather than actual measurement.

It was necessary, some years ago, to arrive at a reasonable basis for comparing the operating performance characteristics of arresters, and standards were finally set up which admittedly are on a basis which is somewhat empirical. The test wave for arresters having a maximum permissible line to ground voltage of 6 kv or less is specified as 50 kv per microsecond, while the test wave for arresters having a maximum permissible line to ground voltage above 6 kv and including 15 kv is specified as 100 kv per microsecond.

Lightning arresters have not only a breakdown characteristic, but they also have in general a potential drop across the arresters due to the flow of current through the resistance in series with one or more gaps provided in the arresters. With all types of distribution arresters this potential drop, or *IR* drop as it is usually called, increases as

A paper prepared by the lightning arrester subcommittee of the AIEE committee on protective devices, and recommended for publication by the committee on protective devices. Manuscript submitted March 23, 1937; released for publication March 25, 1937.

| | Min | 12 0 | 7.5 | 8.5 | 9.5 |
| 6 | Max | 45.0 | 27.0 | 30.0 | 32.5 |
| | Ave | 34.5 | 20.5 | 23.0 | 25.0 |
| | Min | 24.0 | 14.5 | 16.0 | 17.5 |
| 9 | Max | 64.0 | 40.0 | 44.0 | 48.0 |
| | Ave | 49.0 | 30.5 | 34.0 | 37 0 |
| | Min | 34.0 | 21.5 | 24.0 | 26.0 |
| 12 | Max | 75.0 | 52.5 | 58.5 | 62.5 |
| | Ave | 58.0 | 40.5 | 45.0 | 48.0 |
| | Min | 41.0 | 28.5 | 31.5 | 33.5 |
| 15 | Max | 86.0 | 65.5 | 73.0 | 78.0 |
| | Ave | 66.0 | 50.5 | 56.0 | 60.0 |
| | Min | 46.0 | 35.5 | 39.0 | 42.0 |

Gap breakdown taken on rate of voltage rise of 50 kv per microsecond for 3 kv and 6 kv arresters, and 100 kv per microsecond for 9 kv, 12 kv, and 15 kv ratings.
All arresters tested with a 10 x 20-microsecond wave.
The 60-cycle spark potential of all arresters shown in this tabulation will not be less than 150 per cent of the arrester rating.
* These ratings are maximum permissible line to ground root-mean-square voltages.

the current increases, but not linearly. Therefore, data relating to the potential across the arrester during the time of current flow are necessary for the proper evaluation of the long time protective ability of the arrester.

The present Standard requires a test current having a crest value of 1,500 amperes, with a rate of current rise of 150 amperes per microsecond and a decay to half value in a time not less than 10 microseconds. Certain tolerances are, of course, permitted. Since, however, the current values to be expected in practice are known over a considerable range of values, performance data at other current magnitudes than those specified in the Standard are required.

To make these necessary data generally available to the industry, the lightning arrester subcommittee has asked the manufacturers of arresters to submit information on their products, with respect to breakdown characteristics under standard rates of rise as outlined and *IR* drops for crest values of current of 1,500, 3,000, and 5,000 amperes. The manufacturers have supplied this information together with the expected tolerances in production. With these data available, table I and the accompanying graphs have been prepared showing the protective characteristics of line type arresters rated 3 kv to 15 kv.

The impulse breakdown data from table I are plotted in figure 1, showing not only average values, but also the maximum and minimum. Figure 2 shows the maximum, minimum, and average *IR* drop characteristics for the standard current wave of 1,500 amperes crest. The corresponding potentials across the arrester for 3 values of current are shown on figure 3. In each case where average values are given, they are the numerical average of the average value given by the manufacturers. The maximum and minimum values for each make of arrester were obtained by applying the tolerances given by each manufacturer to his average value. For each rating, the highest and lowest values of the maximums and minimums were selected as representing the total spread in performance characteristics.

It is hoped that these data as here presented will be of material assistance in determining the proper place of the lightning arrester as a protective device. The comparison between the surge voltages allowed by an arrester under various conditions and the performance characteristics of other apparatus associated with the arrester should lead to an intelligent evaluation of the protection provided by the arrester.

# Coincidental Electric Drives

By L. E. MILLER
MEMBER AIEE

A "coincidental electric drive" may be defined as a drive consisting of several units of one machine, or a group of machines; each unit or machine driven by a separate motor. For successful operation, each unit or machine must have a speed bearing a definite relation to the speed of each of the other units. This speed relation may be constant or varying.

In operating a coincidental drive, 2 classes of speed must be considered, designated as primary speed and secondary speed. The primary speed is the speed of a group of motors as a whole. The change in this basic speed is of greatest importance, since the speed must be changed in order to change the output of material from the machine.

The secondary speed is that speed of any of the individual units, differing from the primary basic speed, and which accomplishes a successful degree of coincidence between the various units or machines in the drive. In operating a group drive, it is desirable to separate the means of accomplishing primary speed changes from the means of accomplishing secondary speed changes. With a-c motors, primary speed changes can be readily accomplished by changing the frequency, and, therefore, the basic speed of the whole system. On d-c drives, the primary speed change can readily be accomplished by changing the applied voltage, thus changing the basic speed of the whole system.

Secondary speed changes are much more easily accomplished in d-c drives than in a-c drives, since changes may be accomplished by change in field strength of individual motors. Due to the ease with which this secondary change may be accomplished on d-c motors without affecting primary speed changes, d-c motors are used more frequently in coincidental drives than are a-c motors.

To consider drives consisting of 2 or more motors which must operate in a different speed relation to each other, a review is desirable of that which basically determines the speed at which any motor, a-c or d-c, will operate. A clear understanding may be possible if the subject is approached from the standpoint of torque required and torque produced by the motor. If, at any instance, the torque produced by the motor exceeds the torque required, the excess torque will result in acceleration of the motor. If the torque required is in excess of the torque produced, the motor will decelerate. The acceleration or deceleration will continue until the torque balance is established.

If there is a change in certain of the electrical values, such as the voltage on d-c motors, or the frequency on a-c motors, the speed will certainly be affected, because these changes in electrical values will have an effect upon the torque produced. This change in speed, either upward or downward, will continue until the torque balance is again established. If the torque demand changes, an unbalance will result and there will be a speed change either upward or downward, which will result in such a readjustment of the electrical factors as to accomplish the torque balance; at which point there will be no further change. This method of approach requires no distinction between a-c or d-c motors, and is universal in its application.

The torque of either a d-c or an a-c motor is represented by the following equation: Torque = a constant × number of conductors in the rotor × flux per pole × the current per rotor conductor × the cosine of the angle between the stator and rotor flux. (In the case of a d-c motor this cosine is 1.)

In either an a-c induction motor or a d-c motor, a reduction in the speed of the rotor results in an increased rotor current with a consequent increased torque, other conditions remaining the same. (In the case of an a-c motor, this resulting increase in torque continues only until the breakdown torque of the motor is reached.)

Coincidental electric drives are very largely used in the handling and processing of material. If, during the handling or processing, there is no elongation or contraction of the material, it is quite obvious that each unit or machine must operate at such a speed as to handle the same length of material per minute. If there is elongation, each following section or machine must handle a longer length of material per minute. If the speed of the following section is too slow, loops will develop. If the speed of the following section is too fast, excessive tension will be produced in the material, possibly resulting in slippage or breakage. The process may require the reeling of material on a spindle with a constant rate of delivery of the material in the reel. The speed of the reel must decrease in proportion to the increased diameter of material and reel.

Considering again the definition previously given for coincidental electric drives, it can be seen that this definition may be expanded to cover a number of drives used in industry. For convenience, such coincidental drives may be grouped under 4 headings:

### True or Exact Coincidence

In such a drive, the various motors may operate at exactly the same speed. The electric clocks throughout the country may be considered as an illustration of this type of coincidental drive. Another illustration is the use of 2 motors, each driving one-half of a leaf bridge. Still another and quite interesting illustration is the remote control of a steering gear on a ship by means of a synchrolock.

A paper recommended for publication by the AIEE committee on general power applications. Manuscript submitted March 5, 1937; released for publication March 31, 1937.

L. E. Miller is electrical engineer with The Reliance Electric & Engineering Company, Cleveland, Ohio.

### Adjusted Coincidence

This group covers those drives where some modification of true coincidental relation is required, but after this relationship has been established, it becomes fixed and does not change. This may be illustrated by a sectionalized paper machine drive where there is some draw or shortening of the paper due to the drying process.

### Approximate Coincidence

This heading is used to cover those drives where various units operate at approximately a fixed speed relation, but where for short periods there may be a considerable departure from coincidental speed with the final recovering of the over-all coincidental relation. A textile range with storage boxes furnishes an illustration of this type of drive, as does also a continuous pickling line with storage pits.

### Instantaneous Coincidence

Under this heading may be classed a drive where the desired speed relationship between the different units is constantly changing at a predetermined rate of change. One of the more interesting cases of instantaneous coincidency in practical application occurs in the winding of strip material on a reel and maintaining approximately constant tension at the time. In such cases, coincidency between the mill and the reel must be maintained from the time the strip is first drawn taut by the reel until the strip leaves the mill, but as can readily be seen, the relations required for coincidency change inversely as the diameter of the roll of material changes.

In drives of this type, it is not only necessary to obtain coincidency in speed, but it is also desirable to obtain uniform tension during the reeling of the material. This uniformity of tension has been especially stressed in the reeling of metallic strips in order to obtain more accurate strip and to obtain this result with less annealing between rollings. Slipping clutches have been used in the past on many such drives, but since they fail to function as well as desired, and since they do not even approach uniform tension, there has been a constant demand for other and more accurate means of accomplishing the results desired.

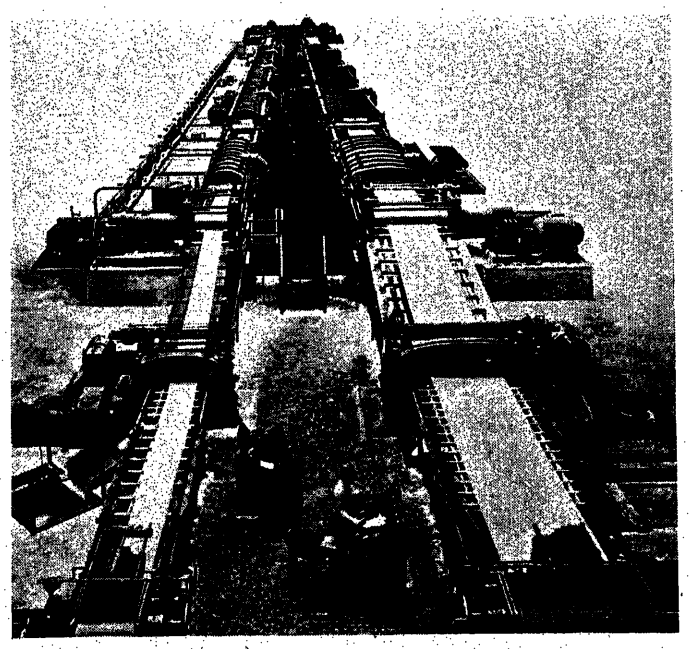

**Fig. 1. A continuous pickling line illustrating an application of approximate coincidence**

The ideal condition for an application of this sort is obtained when the torque produced by the driving unit varies directly with the diameter of the roll on which the material is being wound, and since the diameter of the roll varies inversely with the speed at which the roll must rotate, we arrive at the conclusion that the torque of the driving unit must vary inversely with the speed at which the driving unit operates.

A d-c motor, having its armature current maintained constant by varying its field, fulfills this requirement for all practical purposes, since as is shown in the torque equation, its torque varies directly with its field strength, and its speed varies inversely with its field strength. The problem in producing such a drive, therefore, becomes one of producing a regulator which will automatically maintain a constant current in the armature of a d-c motor by adjustment of the field strength.

An ideal type of regulator should:

*a.* Respond rapidly to changes in current, and adjust its rate of response to the current change required.

*b.* Continue its change in the field strength until current change is entirely corrected.

*c.* Respond to small changes of current.

*d.* Respond properly to either an increase or decrease in current.

*e.* Make minimum change in field strength to get proper correction in current.

*f.* Be sufficiently dampened in action to prevent causing surging.

Various types of regulators have been used in maintaining constant current on such applications. Of these, the following four are the most common. Each has given satisfactory results.

1. The vibrating type relay having one or more contacts connected across fixed resistors was probably the first type used.

2. A motor-driven rheostat, with the direction of armature rotation of the regulator controlled by relays responsive to the current in the reel driving motor armature, was developed as early as 20 years ago.

3. A regulator consisting of vertical stacks of graphite or carbon plates with silver inserts near one end arranged to tilt by the action of a torque motor, which is responsive to the current of the armature of the driving motor, has been used on many applications.

4. The regulator with which the author is most familiar is sufficiently different from the regulators previously mentioned, to merit a more detailed description. It is felt that in this regulator are incorporated those features of a good regulator previously mentioned. This regulator consists of a control motor and a rheostat which is in series with the shunt field of a driving motor. The rheostat is made up of a number of resistance tubes having a large number of taps. These taps are connected to a commutator. A slip ring is mounted at one end of this commutator and this ring is electrically connected to the last tap of the rheostat. Thus it can be seen that the commutator and ring form parallel electrical paths.

The control motor, in its mechanical construction, is quite similar to a small d-c motor except that it has 2 separate and distinct windings on the armature; each

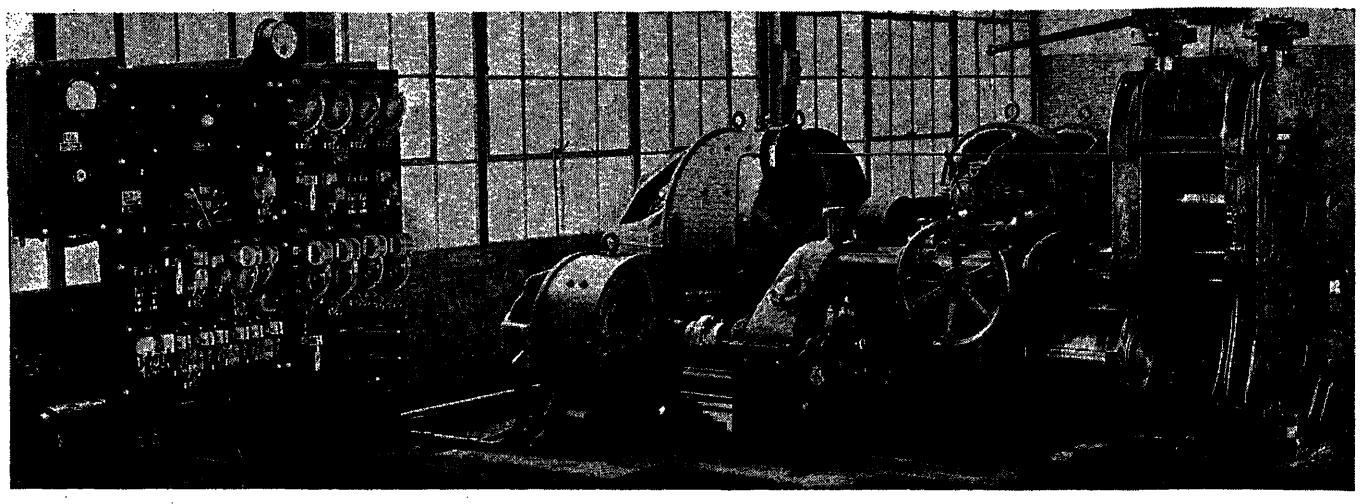

**Fig. 2. A mill and wind-up reel illustrating an application of instantaneous coincidence. Strip is delivered directly from the mill to the reel**

winding being connected to its own commutator. One winding, referred to as a spring or reference winding, consists of a large number of conductors of a small cross-sectional area. This might be considered as a very slow speed motor winding. It is connected in series with a resistance across a constant potential line. It gives the effect of a very long spring capable of being extended an infinite distance without changing the force produced.

The second winding is referred to as the torque winding, and consists of a fewer number of turns of a larger cross-sectional area. This winding might be considered as an ordinary high speed motor winding. It carries a definite proportion of the current passing through the armature of the motor being regulated.

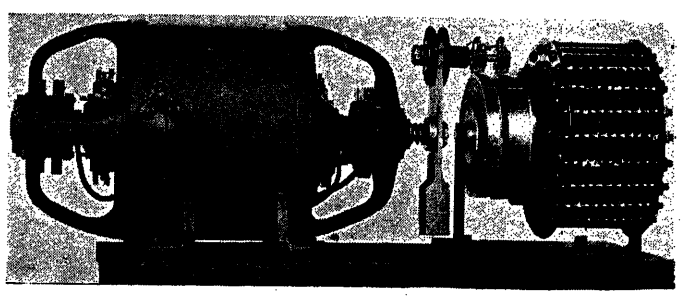
The armature with its 2 windings operates in the flux field of a conventional d-c motor, and hence, current passing through either or both of the windings tends to produce rotation of the armature. The shaft of this combination armature has an arm mounted on it which carries 2 brushes electrically connected to each other, but insulated from the arm. One of the brushes rides upon the commutator of the rheostat mentioned before, and the other rides upon the slip ring which is electrically connected to one end of it. The result of one complete revolution is to change the condition of the rheostat, step by step, from a condition of full resistance to a condition of zero resistance.

The windings of the control motor are so connected that the current passing through the torque winding causes rotation in a direction tending to reduce the resistance in the rheostat, while current passing through the spring or reference winding causes rotation in a direction tending to increase the resistance in the rheostat. Thus, it can be readily seen that a condition of balance can be obtained which will cause a stationary condition of the armature, but when this condition of balance is disturbed by a change in the current in the torque winding, a rotation causing a corrective change in the rheostat will be produced. This rotational correcting action will continue until correction is established.

In regulating devices performing a function similar to that described there is frequently a tendency to hunt or to cause hunting on the part of the motor they are controlling. This is especially true of devices which tend to give true correction, and where the strength of the response to change is, as it should be, proportional to the change in current. This, of course, can be eliminated by dash pots, frictions, clock escapements, and other mechanical means. All such means, however, introduce friction which reduces the sensitivity of the regulator, since the frictional part of the retarding force is the same regardless of whether a small or large correction is indicated.

To remove this possible cause of trouble, a copper cylinder surrounding the armature of the control motor is introduced. This serves as an effective dampener and does not reduce the sensitivity for small changes in current. When the change in current is small, the rotation is slower, and the dampening action is negligible. When the change is current is large and the tendency to respond is greatly increased with the possibility of over-running and causing hunting, the dampening action from the cylinder is increased as the square of the change in speed of the control motor.

Referring to figure 4, we have a simplified schematic diagram showing the connections for a typical application making use of a regulator such as described. A generator $G$ is connected mechanically to a mill for processing material. This generator $G$ supplies a source of potential



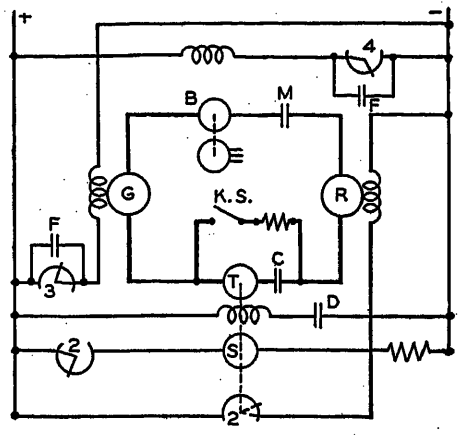


**Fig. 3. A constant-current regulator of the type described in the context. The cover has been removed from the rheostat to give a clearer view**

*R*—Reel motor

*D*—Regulator field rheostat
*F*—Field rheostat shorting contactors

**Fig. 4. Simplified schematic diagram of connections as used with the regulator described**

to operate a reel motor *R*. Connected in series with the generator *G* and reel motor *R* is an independently driven booster generator *B*. This generator *B* supplies current to the reel motor when the generator *G* is stationary, and thus maintains a tension on the material between the mill and the reel, when the mill is shut down while material is still being processed.

Since the generator *G* operates at the same speed as the mill, the normal speed of the reel motor *R* will be such as to give the same lineal speed of take-up material as is being delivered by the mill. Adjustments from the normal speed of the reel motor *R* to accommodate the build-up of material on the reel are automatically produced by the regulator rheostat.

The torque winding *R* of the regulator, parallel with an adjustable resistance, is connected in series with and between the generator *G* and the reel motor *R*. The spring winding *S* of the regulator is connected in series with a fixed resistor and an adjustable rheostat across a source of constant potential. The regulator rheostat 2 is connected in series with the shunt field of the reel motor *R* and across a constant potential. Major changes in tension, produced by changing the current at which the regulator functions, are caused by changing the adjustable resistance paralleled with the torque winding, and minor or vernier changes are accomplished by changing the rheostat in series with the spring winding.

The operation of the regulator is such that once the balanced condition is predetermined and set, an increase in current will cause the torque of the torque winding to overcome the torque of the spring winding, and the rheostat arm will be moved in a direction to increase the field strength of the motor being regulated. This motion will continue until correct current is established. A decrease in current will have an opposite effect, and motion will be in the direction of decreasing the field strength.

In studying regulators, such as the one described and others, we should not be misled into thinking that we have absolute accuracy of tension at all times. A motor is not a meter, and even a meter is not absolutely accurate. By this we do not refer to the calibration inaccuracy which is common with most meters, but rather, due to its dampening and inertia, to its lack of instantaneous accuracy. In a motor we have similar inaccuracies considerably magnified. For instance, in a motor we have a dampening action due to the inductance of the armature circuit. Also, we have present an inertia not only of a motor armature, but also of the mandrel on which the material is being wound, as well as the material on the mandrel.

No method has as yet been developed that will maintain constant tension by the use of a regulator or other device during the accelerating or decelerating period. It should be pointed out that extra current is necessary during the accelerating period. However, since the accelerating rate will vary from time to time, and the frictional losses will be more or less variable, the extra torque for acceleration can bear no fixed relation to the torque required to produce tension; and the current cannot be determined with any degree of accuracy. On the other hand, it is generally desirable to cause, either by the regulator or other control devices, extra current to flow during the accelerating period. The reverse of this is true during the decelerating period.

In view of the fact that it is difficult to determine by watching meters just what is taking place in one of these wind-up drives, it would seem that a better study could be made by the use of undamped oscillograph readings. Such readings have been made on a typical application of a drive of this sort.

Oscillogram figure 5 shows the speed, armature voltage, armature current, and field current. The film was taken during the final period of winding a coil from strip steel. The armature voltage is apparently quite steady. The speed shows, as it should, a steady decrease. The field current shows indications of vibrations of small amplitude and a steady increase in value. This again is more or less normal. The armature current shows variations of small amplitude, and the maximum change in value is about 5 per cent. This does not come, as can be noted, in the form of a gradual increase from the beginning to the end of the process, but occurs only as infrequent peaks or valleys. The mean change appears to be not exceeding 3 per cent.

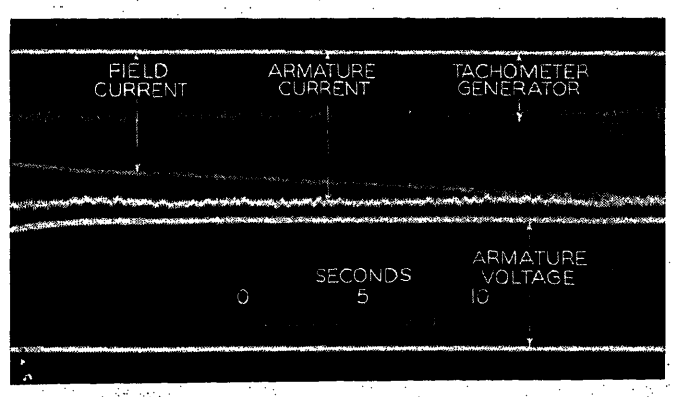

**Fig. 5. Oscillogram obtained during the winding of strip steel into a coil. Shows gradual rate of change of motor field current and speed, and approximately constant armature current and voltage**

Oscillogram figure 6 is a continuation of oscillogram figure 5 carrying the build-up to very close to its final value. The characteristics are the same as in figure 5. It is impossible to see the rheostat steps in the field current curve, since there are 180 steps in the rheostat, and the change per step is only about 0.04 inch on the original 6-inch wide film. From the film we find that the regulator responded rapidly enough to keep the current from varying to any great extent from the predetermined value, and the response was not so rapid as to give any tendency toward a hunting condition. Visual observation bore out the fact that the regulator did not over travel, and, therefore, did not have to correct itself by returning from a too advanced position. This test was made on a reel driven by a 100-horsepower 3- to 1-speed range motor. The build-up on this particular coil was such as to cause the motor to operate through a speed range of 2 to 1, and required about $^3/_4$ of the normal full load rating.

In attempting to get as much of a complete run as possible on one oscillograph reading, the film was, of necessity, run at a very slow speed. In doing this, however, as can be noticed, the peaks and valleys of the armature current reading were so bunched together as to make an almost solid line. A further study was desired in order to bring more plainly into view the actual fluctuations of the armature current. Figure 7 shows the results of this study. In this case the film speed was increased to about 6 inches per second, as can be seen by the timing wave made from a 60-cycle power supply. Here the curve of armature current was sufficiently elongated to give a very definite view of the peaks and valleys separated from each other. On this curve, the armature voltage shows 2 very definite frequencies, one a comparatively low frequency with a change of not very great amplitude, and another a quite high frequency with a change of an even smaller amplitude. The ripple of vibration in the voltage curve does not seem to bear any particular relation to the ripple found in the armature current curve, but no doubt, has some influence on it. Another fact which may have had some influence in causing a variation in the armature current was noted in watching the actual winding up of the strip upon the mandrel. The catch for securing the strip to the mandrel projected beyond the periphery of the mandrel, causing an eccentric shaped coil. This was only a minor eccentric-

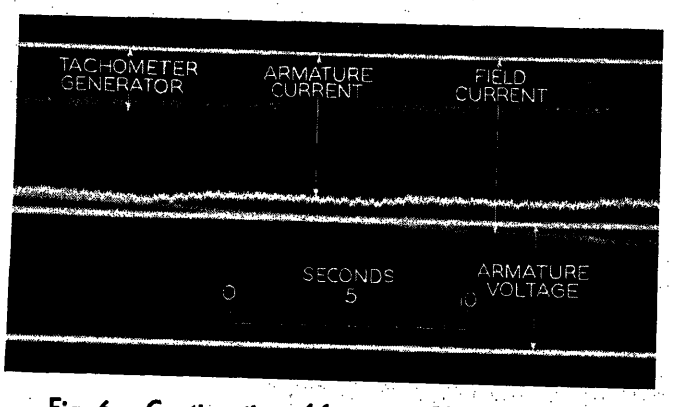

**Fig. 6. Continuation of figure 5. The coil has now approached its maximum size**

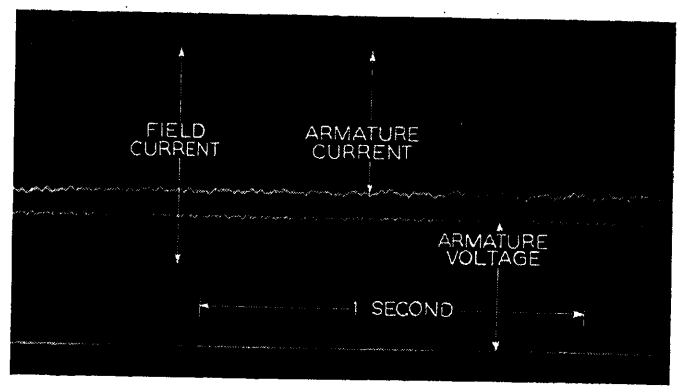

**Fig. 7. A higher speed oscillogram of the same operation as figures 5 and 6. Peaks and valleys occurring in armature current are shown in more detail**

ity, and while theoretically it had some effect upon the armature current, we are not justified in concluding that it was the entire cause of the ripples occurring therein.

In considering an application of this type, there is still another inaccuracy present which should be recognized; namely, the frictional losses in the motor, gears, and reel. When operating near the normal load, this inaccuracy is for all practical purposes negligible, but when operating at very low loads, as may be the case when only one mill and reel are available to cover a wide range in tension, this inaccuracy can easily become very material.

As an example of this, let us assume the current required to produce the torque to overcome friction is 10 per cent of the normal current rating of the motor, and let us assume that current variation permitted by the regulator is 5 per cent, as shown in oscillograph figures 5, 6, and 7. Then if the current required for overcoming friction and producing tension is 100 per cent of the normal rating, the variation in tension will be $5/(1.00 - 0.10) = 5.56$ per cent, which is a very good result. If, on the other hand, the current required to overcome friction and produce tension is assumed to be 20 per cent of the normal rating of the motor, then the variation in tension will be $5/(0.20 - 0.10) = 50$ per cent. This may be satisfactory on many applications, but is certainly too great on many others, and seems to indicate the possibility of unsatisfactory operation in attempting to make a mill and reel cover too great a range in tension. It is the author's belief that a 5 to 1 range in tension is as high as is practicable in an application of this type.

## Conclusion

Coincidental electric drives are being used more and more in industrial applications. Many such drives have been applied with insufficient knowledge of the actual requirements of those drives, and with insufficient study of the details of that which must be accomplished to produce a successful drive. Some of these drives are now working with passable, although not entirely satisfactory, results. Improvements, both as to economy and operation, can be expected in the future by the study of those drives already applied, and by continued effective co-operation between the operating and manufacturing engineers.

# Impulse Operation of Magnetic Contactors

By CARROLL STANSBURY
MEMBER AIEE

Magnetic contactors as commutating devices for the application of power for very brief periods (as in resistance welding practice) have encountered limitations which have been considered inherent in their nature. The author has found that this is not necessarily the case, and describes a method of operating magnetic contactors which to a great extent avoids the usual limitations and gives short periods of great accuracy.

THE MAGNETIC contactor has been one of the most important factors in the application of electricity to industry. Although its most extensive use in the past has been in motor control, another application of great and growing importance in recent years has been in the resistance-welding industry. The duty which the contactor is called on to perform in this field is the commutation of a single phase circuit of low power factor, with loads ranging from 1 or 2 kva up to over 1,000 kva. The periods of power application vary from 2 or 3 cycles up to one second or more (references 1, 2, 3, 4).

There are certain very important classes of resistance welding, however, on which it has been found essential to use periods of power application which are too short for the use of magnetic contactors by conventional methods. Such welding includes the welding of aluminum alloys, stainless steel, and various light welding of nonferrous metals in small light parts where the extreme localization of heat resulting from short-time welding is advantageous, (reference 5). The timing periods involved are on the order of 1 or 2 cycles or even $^1/_2$ cycle in some cases.

Cam-operated contactors driven by synchronous motors have been used for this purpose and also all-electronic controllers using thyratron and ignitron tubes have been widely applied (references 6, 7, 8, 9, 10). (Reference is here made to control for single spot welding as distinguished from the type of seam welding control which consists of a series of over-lapping spots applied at very high speed through roller electrodes.)

The magnetic contactor has not been able to enter this field successfully heretofore because certain limitations appeared to mark off a range of application below about three cycles to which it is not applicable. However, in the natural competition of ideas and practices it was inevitable that attempts would be made to overcome these limitations. The incentives for such attempts were considerable, provided magnetic contactors could be applied to this field with a simplicity and cheapness comparable to that with which they are applied to the less critical installations.

A paper recommended for publication by the AIEE committee on general power applications. Manuscript submitted March 4, 1937; released for publication March 17, 1937.

CARROLL STANSBURY is employed in the development department of Cutler-Hammer, Inc., Milwaukee, Wis.

## General Problem

It will perhaps best bring out the nature of the problem to suppose at first that power is to be supplied to a single-phase load in separate periods of 10 cycles duration. If a contactor of suitable size is selected and oscillograms relating magnet-coil current to the closed or open condition of the main contacts are examined, it is found that if the coil circuit is closed at a given instant, the main contacts will touch about 2 cycles later, and that the contactor magnet will seal about 2 cycles after that.

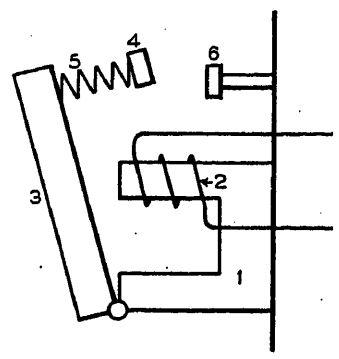

**Fig. 1. Essential elements of typical magnetic contactor**

Elements represented are: stationary magnet structure 1, magnet coil 2, armature 3, moving contact 4, contact spring 5, stationary contact 6

Magnetic blowout and return ("tail") spring omitted for simplicity

Similarly, in opening, the contactor requires about 2 cycles after the coil circuit is interrupted before the main contacts separate. To meet the above requirements, therefore, some sort of timing device is used which closes the magnet circuit for 10-cycle periods. Its contacts close 2 cycles before the main contacts touch, and open 2 cycles before the main contacts separate. For purposes of the present analysis it will be assumed that the timer used is non-synchronous in action. That is, the closing and opening of its contacts are at random relative to the phase of the alternating supply voltage.

The timing results obtained would be somewhat disappointing if accurately measured, for reasons which would include some or all of the following:

1. The timing device itself would probably have an error of $\pm^1/_2$ cycle or more
2. There would probably be a variable amount of arc on the pilot-device contacts, affecting the accuracy of commutation of the coil circuit
3. Due to the nonsynchronous closing and opening of the coil circuit of the contactor, variable transients would occur affecting the duplication of action of the contactor magnet
4. The use of a contactor with an a-c magnet involves having a direct iron-to-iron seal on the magnet face. The actual sealing

would be slightly different each time, which would affect the accuracy of opening of the contactor

5. There would be a variable amount of arc on the main contacts of the contactor.

None of these factors is serious at 10 cycles, but all become increasingly so as the required period is reduced. Experience has shown that 3 or 4 cycles is the lower limit for most applications, because the percentage variation in the energy input to the weld becomes excessive at shorter periods.

It is possible to set up a specification for an ideal program of energizing the contactor magnet simply by prescribing that the above defects should be absent. Such a specification would be something like the following:

1. The timing device proper must be accurate to a very small fraction of 1 cycle.

2. The pilot device must operate without arc.

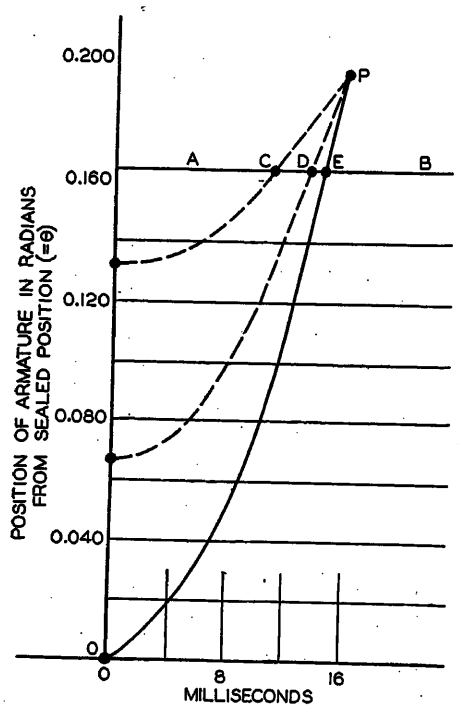
3. The timing device must be synchronous in operation.

4. The contactor magnet must operate without direct iron-to-iron seal.

5. Arc on the main contacts must either be eliminated or be held to a uniform effect.

## Accurate Timing Element

The essential elements common to practically all magnetic contactors are indicated schematically in figure



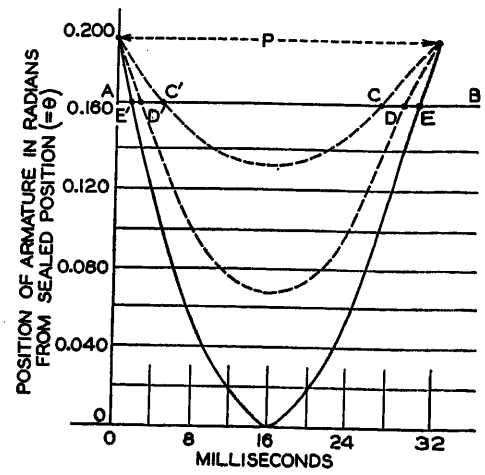


**Fig. 2. Curves representing opening motion of magnet armature**

1. It is immaterial for the present discussion whether the armature is hinged or slides, or whether it moves horizontally or vertically. The number of contacts and contact springs is also immaterial.

In a typical magnetic contactor of average size the moving armature 3 is a laminated steel structure weighing several pounds. It constitutes as high as 85 per cent of the total mass which is set in motion by the magnet. In order to obtain fast operation for resistance welding and similar applications, design tendencies have naturally been toward reducing the moving mass, increasing the magnet pull by using intermittent duty coils, and increasing the opposing spring forces in contact springs and tail spring, if used.

When a magnetic contactor is energized, only part of the armature travel is completed when the contacts meet. Further forward movement of the armature is necessary (during which contact spring 5 compresses) to

**Fig. 3. Motion of armature during impulse operation of contactor**

provide for contact wear and for magnet travel during opening before the contacts separate, so that suitable separating speed may be attained. Expressed briefly, armature movement equals arc gap plus wear allowance.

Assume that the magnet is holding its armature in the sealed position with the contact spring 5 correspondingly compressed and that the magnet is then de-energized. The resulting outward motion of the armature is that of a mass accelerated by a spring (frictional and gravity forces being small compared with that produced by the spring). Then if

$I$ = moment of inertia of armature
$T_s$ = initial outward torque due to contact spring
$\theta$ = angular travel of armature outward from sealed position
$t$ = seconds after initial instant
$K$ = reduction in contact spring torque per radian of opening motion

$$I\frac{d^2\theta}{dt^2} - (T_s - K\theta) = 0 \qquad (1)$$

The solution of this is (assuming $\theta = 0$ when $t = 0$):

$$\theta = \frac{T_s}{K}\left[1 - \sin\sqrt{\frac{K}{I}}\left(t + \frac{\pi}{2}\sqrt{\frac{I}{K}}\right)\right] \qquad (2)$$

If $I$ is in pound-inches,[2] $T_s$ in inch-pounds, $K$ in inch-pounds per radian, and $\theta$ in radians:

$$\theta = \frac{T_s}{K}\left[1 - \sin\sqrt{\frac{12 \times 32.16K}{I}}\left(t + \frac{\pi}{2}\sqrt{\frac{I}{12 \times 32.16\,K}}\right)\right] \qquad (3)$$

Using equation 3, the angular motion of the armature may be plotted as a function of time as in figure 2, wherein the full-line curve shows the armature motion following

its release from the sealed position (the curves of figure 2 apply to an actual contactor which may be considered as typical).

Now if the armature were held at some position intermediate between the sealed position and that at which the contacts just touch, as at $B$ or $B$,[1] and released, equation 3 shows that the armature would move in accordance with the corresponding dotted curve of figure 2. It can be shown that these curves constitute a family all of which intersect at point $P$, which is the angular position

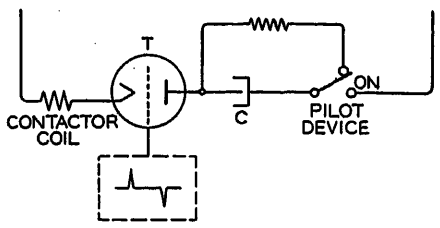

**Fig. 4. Circuit providing actuating current impulse for contactor coil—charging type**

at which deformation of the contact spring 5 is entirely relieved. However, in an actual contactor the contact spring 5 is restrained by a mechanical stop of some sort before this point is reached. As a result, the contact 4 is moved away from engagement with contact 6 at the angular position of the armature represented by the line $A$—$B$. The slope of the various curves at points $C$—$D$—$E$ is proportional to the speed of separation of the contacts.

Evidently the process of acceleration of the armature by the spring is reversible. This fact is represented by figure 3. If the armature were in some way caused to move in the closing direction at an angular speed corresponding to the slope of the curve at $E^1$ at the instant the contacts engage, its movement thereafter would be in accordance with the full-line curve, and the total period during which the contacts would maintain a closed circuit would be represented by the interval $E^1E$. (This statement neglects friction losses, which experiment proves to be justifiable.) Similarly, a slower armature speed at the instant the contacts touch would result in movement in accordance with one of the family of dotted curves, with slightly reduced interval. The only reason the interval is reduced is the restraint of the contact spring, as explained above.

We are thus dealing with the inherent period of the mechanical system consisting of the contactor armature and the contact spring. The armature might be likened to the balance wheel of a watch, while the contact spring plays the part of its hair spring. Operated in this way the contactor is its own timing device.

If the mechanical arrangement were such that the armature could oscillate in both directions under influence of the spring, it can be shown from equation 3 that the period of full oscillation would be

$$2\pi\sqrt{\frac{I}{386K}}$$

Therefore the interval $p$ in figure 3 is

$$p = \pi\sqrt{\frac{I}{386K}} \qquad (4)$$

It would appear from the above that a contactor timed in this way is inherently inflexible as far as time adjustment is concerned. In fact it is the fixed nature of the timing which gives the system its inherent stability and reliability. Nevertheless, it is found to be a simple matter in practice to obtain timing adjustments over a sufficient range, as will be brought out in a later paragraph.

## Actuating Impulse

It was assumed in the foregoing that the armature was in some way to be put in rapid motion prior to the instant the contacts touch. It was further assumed that the application of the accelerating force would not be continued after that instant. This could be done mechanically by the action of a motor-driven cam, by the sudden release of a compressed spring, by pneumatic means, etc., etc. However, it has been found most convenient and satisfactory to accomplish this by momentarily energizing the contactor coil by a single unidirectional pulse of current. A suitable current pulse for this purpose must be accurately reproducible and it must bear a definite phase relation to the a-c supply voltage. Other desirable characteristics will appear later in the description of the control. Apparently the simplest method of generating suitable current pulses is by the use of charging or discharging currents of capacitors.

Figures 4 and 5 show the 2 alternative circuits which have been successfully used in practice. It will be seen that both circuits involve a single-pole double-throw

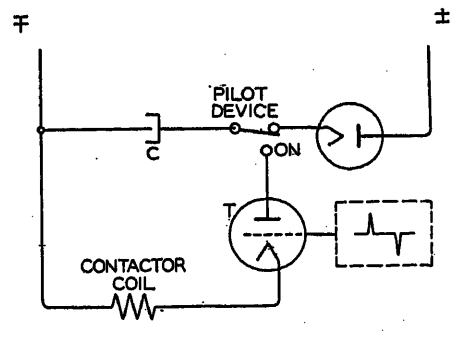

**Fig. 5. Circuit providing actuating current impulse for contactor coil—discharging type**

pilot device, a capacitor $C$, and a thyratron $T$. For either circuit, when the pilot device is put in the *on* position, these elements are connected in series with the contactor coil.

As the contactor coil has both resistance and self-inductance, the circuit of figure 4 (neglecting the action of thyratron $T$) is the classical case of $L$, $C$, and $R$ connected in series with a d-c source (reference 11). (For the convenience of the reader, formulae appropriate to this type of transient are given in an appendix to this

paper, together with a brief description of the method by which the electrical and mechanical performance of a given contactor and circuit may be predicted.)

As is well known, if in the $L$, $C$, $R$ circuit of figure 4, $CR^2 < 4L$ the current flow when the pilot device is closed will consist of a series of damped oscillations (or would, but for the presence of the thyratron $T$). This is illustrated in figure 6 which was made with the thyratron omitted. By way of comparison, figure 7 illustrates the

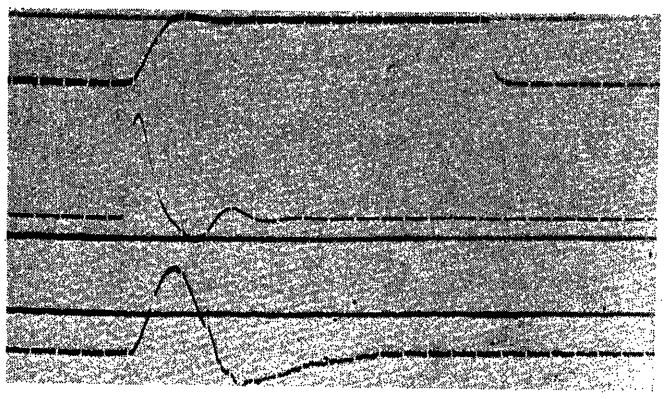

**Fig. 6. Oscillogram of impulse operation of contactor**

Actuating current as in figure 4, except thyratron omitted
Upper trace—Potential across capacitor $C$
Middle trace—Magnet-coil current
Lower trace—Magnet armature motion
Interruptions in trace are at one-cycle intervals

case in which the constants are such that no current oscillations occur.

Examination of the type of current pulse in figure 6 or 7 shows neither to be well suited for the present purpose, which obviously requires for clean-cut operation a single pulse of current, without either subsequent smaller pulses as in figure 6, or gradual cutoff as in figure 7. The presence of the thyratron $T$ (together with the use of suitable circuit constants) provides for such a pulse by preventing subsequent current flow after the first single half-oscillation. To show this figure 8 was made under the same conditions as figure 6 except for the presence of the thyratron in the circuit. Figure 8 and figure 9 are typical of actual operation with the charging and discharging circuits, respectively.

The thyratron also serves to time the start of the pulse to the desired synchronous relation to the a-c supply to the welder circuit. This triggering action is accomplished by applying a sharp-peaked wave to the grid to allow the thyratron to start conducting (after the pilot switch is closed) only at a definite point in the a-c cycle (reference 12). The phase position of the peaked wave is made adjustable throughout 360 electrical degrees to permit adjustment of the phase of the instant of separation of the contacts.

As explained in the caption of figure 6, the lower trace of each oscillogram shows the motion of the magnet armature. In each case, this trace is shown in relation to 2 horizontal lines, one of which represents the position of the armature with the contacts just touching, while the other represents its position when in the sealed position. These lines were made in turn by holding the armature in the touch and sealed positions, respectively, during a passage of the oscillograph film. The time interval between the 2 points of intersection of the trace of armature travel with the *touch* line therefore corresponds to the actual closed-circuit period. The portion of the trace between these points is equivalent to the curves of motion of figure 3. The quantitative agreement will be evident by comparing figure 8 with figure 3, the timing gaps in the former being at one cycle, or 16.7 millisecond, intervals.

It will be noted in the oscillograms that, after opening, the armature pulls out further than the position of rest

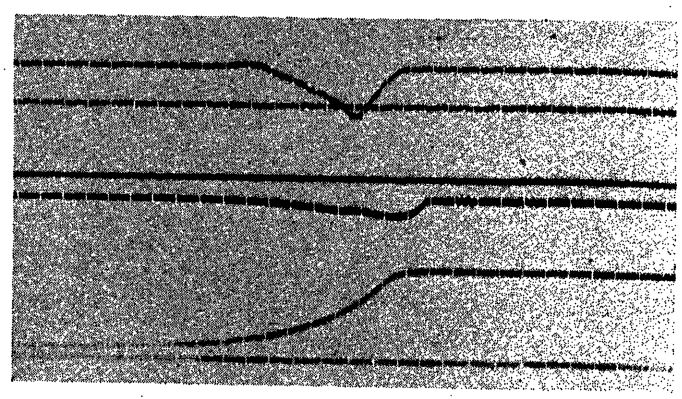

**Fig. 7. Impulse operation with aperiodic actuating impulse**

Circuit as in figure 4, $CR^2 > 4L$

and is then restored thereto in a period of about 4 cycles. This action is possible on this particular contactor because it includes a flexible stop in the open position which has a snubbing action of this type to prevent bouncing.

The operation of the circuit in figure 5 is essentially the same as that of figure 4 except that operation is obtained on the discharge instead of the charging current. Figure 4 is suited for use on a d-c supply circuit whereas figure 5 is suited for a-c supply or may be used on d-c with the rectifying tube omitted.

## Time Adjustment

From the explanation accompanying figures 2 and 3 above, it will be seen that adjustment of timing by mechanical means would be possible, either by use of weights attached to the moving armature, to increase its mass, by adjustment or interchange of contact springs, or both. In practice, however, entirely electrical adjustment by changing the capacity in the circuit is very much more convenient and desirable. Such adjustment results in variation of the speed of the armature at the instant the

contacts touch, and figure 3 shows that some time adjustment is available in this way, as the closed interval can be changed from $E^1$-$E$ to $D^1$-$D$ and so on. Furthermore, by providing more capacity than necessary for sealing the armature, longer periods than that represented by the interval $E^1$-$D$ in figure 3 are available. Experience has shown that, by providing a nonmagnetic spacer to prevent an iron-to-iron seal on the magnet face, quite satisfactory accuracy for longer timing periods up to about 5 cycles is obtainable.

The greatest percentage of the work for controllers of this type is in the short range where the contactor operates on the true impulse basis. Where such short time with suitable accuracy is available in the controller, it is generally preferable to hold the time of application constant and adjust the energy input for different types of work by adjusting the welding current.

The performance curves of figure 3 and the oscillograms herein apply to a contactor having a somewhat higher natural period than would generally be applied to this work. Actual contactors now being used have lighter armatures and higher spring tensions and have a natural closed-contact period of about 1 cycle. Laminated magnets are necessary in order to obtain suitable speed.

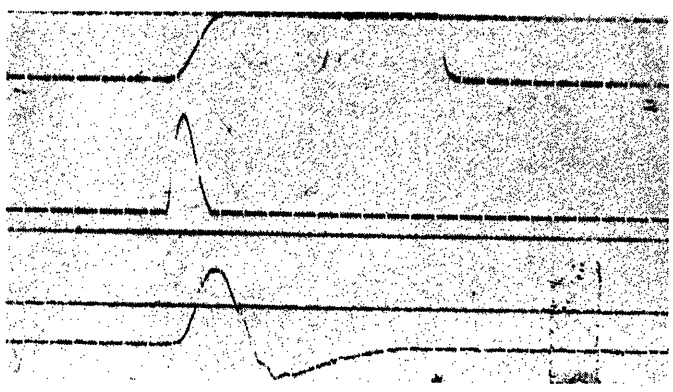

**Fig. 8. Impulse operation with oscillation prevented by thyration**

Circuit as in figure 4; $CR^2 < 4L$
This is normal type of impulse operation with the charging circuit

## Arc on Main Contacts

Phase adjustment of the coil current pulse makes possible adjustment of the instant of opening of the main contacts to avoid objectionable arcing. It is possible to adjust away from a condition of heavy arc, and experience shows that the arc that is obtained is quite uniform and permits excellent uniformity of the welding results. On stainless steel and light nonferrous welding the arcing is not a factor, but it becomes important on the high currents used in aluminum welding.

Automatic means for adjusting the instant of opening of the contacts have been developed and successfully operated. Commercial installations used to date have, however, had manual adjustment only.

## Commercial Applications

Figure 11 shows a commercial impulse controller using the circuit of figure 5. The contactor which is used with this control is of more or less conventional type as far as appearance is concerned, but has an unusually small magnet for the size and capacity of the contacts and has unusually high contact spring pressure in order to reduce its natural closed period to 1 cycle.

Commercial experience covers a period of about 18 months at the time of writing and includes separate installations in regular production service on stainless steel, aluminum, light nonferrous welding, and machine driven operation in one-cycle welding on steel at more than 5 welds per second. The method is particularly suited to applications of the last-mentioned type because operating without sealing the magnet eliminates the principal cause of magnet wear. Operation is quiet for the same reason.

## Conclusions

The method of control described herein conforms to the specifications given in a early paragraph of this paper as essential for successful short period operation of magnetic contactors. Moreover, it results in a contactor control in which the noise of magnet impact, and the problem of magnet wear, are eliminated. The controls built on this principle have fulfilled expectations in service over a considerable period and on a variety of work.

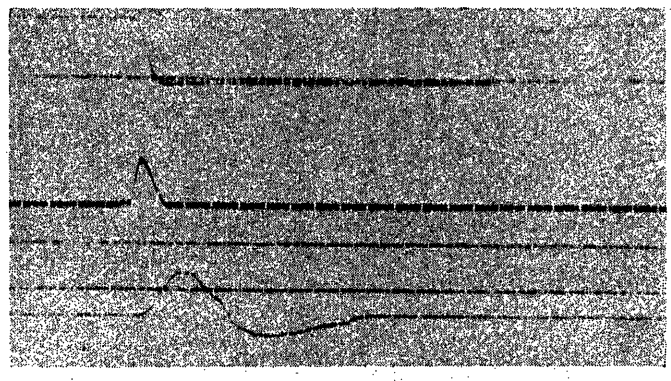

**Fig. 9. Normal impulse operation with discharging circuit**

Circuit as in figure 5; $CR^2 < 4L$

Although the present exposition of the method has emphasized its application to the resistance welding field, this is primarily for purposes of illustration and because that field appears to be the most important immediate application. It is quite possible that the method is applicable as a machine element for other purposes.

## Appendix—Calculation of Armature Motion

In order to predict the performance of a given contactor in impulse operation, it is necessary to have the following information:

1. The self-inductance $L$ and a-c resistance $R$ of the magnet coil as a function of turns and of magnetic gap. (It appears to be a satisfactory approximation to use 1.5 times the d-c resistance for $R$)

2. The pull characteristics of the magnet as a function of ampere-turns and magnetic gap

3. The moment of inertia of the armature, contacts, and other moving parts, both when moving freely and after contacts engage. Calculated values based on estimated gyration radii of components are sufficiently accurate for practical purposes

4. Torque of unbalanced weight and friction torque of armature and other moving parts

5. Torque exerted by contact springs as a function of magnetic gap.

**Symbols**

$i$ = instantaneous coil current, amperes
$e$ = instantaneous potential across capacitor, volts
$E$ = d-c supply volts in figure 4 or initial (fully charged) capacitor volts in figure 5
$t$ = seconds from instant pilot device is put in on position
$L$ = self-inductance of coil, henries
$R$ = a-c resistance of coil, ohms

$$\beta = \sqrt{\frac{1}{CL} - \frac{R^2}{4L}}$$

Although for a given coil $L$ is a variable depending on the magnetic gap, and although the armature is in motion during the passage of the pulse of coil current, analysis of a number of oscillograms of coil current and armature motion has shown that a good approximate prediction of the current pulse is obtainable by using for $L$ the value corresponding to the armature at rest in the open position. Using this value of $L$ it is essential, in order to obtain a circuit in which the current transient has an oscillating tendency, to make $CR^2 < 4L$. If this requirement is met by the circuit constants selected (reference 11),

$$i = \epsilon^{-\frac{Rt}{2L}} \cdot \frac{E}{L\beta} \sin \beta t \qquad (5)$$

for either figure 4 or figure 5. Equations for potential across capacitor are, for figure 4:

$$e = E\left[\epsilon^{-\frac{Rt}{2L}}\left(\cos \beta t + \frac{R}{2L\beta} \sin \beta t\right) - 1\right] \qquad (6)$$

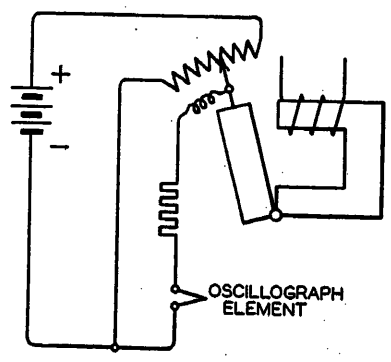

**Fig. 10. Method of recording armature movement on oscillograms**

The brush of the voltage-divider rheostat (mass and friction of which are negligible) is moved by the armature

and, for figure 5:

$$e = E\epsilon^{-\frac{Rt}{2L}}\left(\cos \beta t + \frac{R}{2L\beta} \sin \beta t\right) \qquad (7)$$

By the use of equation 5 it is possible to plot an approximate curve representing the coil current pulse as a function of time for any assumed set of constants.

Having this prediction of coil current as a function of time and the other information listed above, it is a matter of straightforward mechanics to predict the motion of the armature. The method used by the writer for doing this is a step-by-step calculation in which the net torque and resulting acceleration is taken as constant for each of a succession of equal short periods of time (0.002 sec. has been found suitable for the time increments).

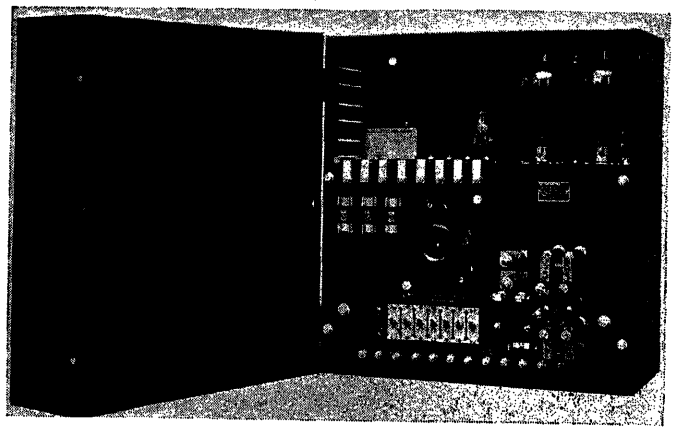

**Fig. 11. Commercial controller for impulse operation of contactor**

Contactor not shown; handwheel in center of panel is for phase adjustment; the row of snap switches is for adjustment of the main capacitor; relay and thermal strip timer allow time for heating of thyratron cathode

# A-C Motor Protection

By C. W. KUHN
MEMBER AIEE

## Synopsis

An investigation of motor protection can be made by a comparison of the proper motor and thermal overload relay data. Convenient data for this are motor "protection" curves for comparison with "tripping time" curves of thermal overload relays. These motor curves should include single phase operation of polyphase motors as this is one of the abnormal conditions for which motors should be protected. The capacity of the motor at different expected ambient temperatures should be compared with the capacity of the overload relay at its corresponding ambient temperatures.

MOTOR PROTECTION is an important consideration in any a-c motor installation. This is recognized in industry by the almost universal use of motor protection. It is of particular importance in the design and use of automatic motor-driven equipment such as compressors, pumps, electric refrigerators, oil burners, and the like, which may represent definite fire hazards as the result of motor failure.

Almost all a-c motor protection today is by means of thermal overload devices. These thermal overload devices are not necessary units for the operation of the motors they protect but increase the use which can safely be made of them. Frequently they are not given the consideration they merit. This is partly due to lack of data, in convenient form, for the adequate consideration of a thermal overload application.

It is the purpose of this paper to outline the data necessary for a study of a-c motor protection by thermal overload devices and to present a method of calculating some of the more important factors based on the usual motor performance curves.

## Motor Characteristics

The important motor characteristics to determine adequate motor overload protection are:

1. "Protection" curve
2. "Locked rotor data"
3. "Load" curve

"Protection" curves show the time required for the motor windings to reach a certain maximum safe temperature. Time values for these curves are preferably measured, starting with windings at 25 degrees centigrade. The temperature rise of the motor windings is conveniently measured by means of thermocouples placed in the motor slots. Figure 1*A* and figure 1*B* show "protection" curves for 2 designs of a-c motors. Curves are included for single-phase operation of polyphase motors. Such single-phase operation may result from a blown fuse and is one of the hazards against which polyphase a-c motors should be protected.

While the curves of figure 1*A* show that any protection satisfactory for polyphase operation would protect the motor when operating single phase, the reverse is sometimes true. Single-phase operation of some polyphase motors results in higher temperatures of the active winding than would be obtained for the same current with normal polyphase operation. This is an important factor in motor design and one which is not always given consideration.

"Locked rotor data" merits special consideration and should consist of the following particulars:

1. Current at normal voltage
2. Current at normal voltage of polyphase motors with only one phase in circuit
3. Time required to reach the maximum safe temperature for 1 and 2 starting with ambient temperature of 25 degrees centigrade

The motor "load" curve shows the continuous load in amperes at which the motor will reach a maximum safe

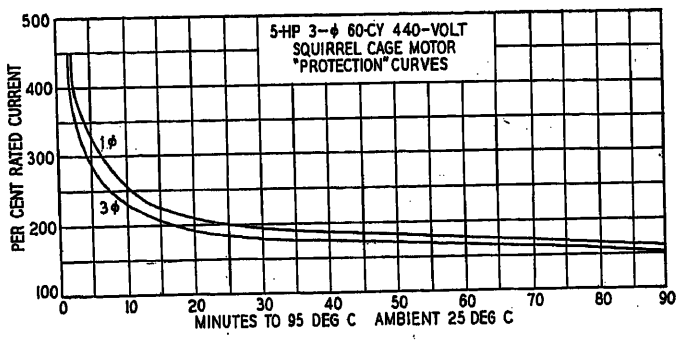

Fig. 1A

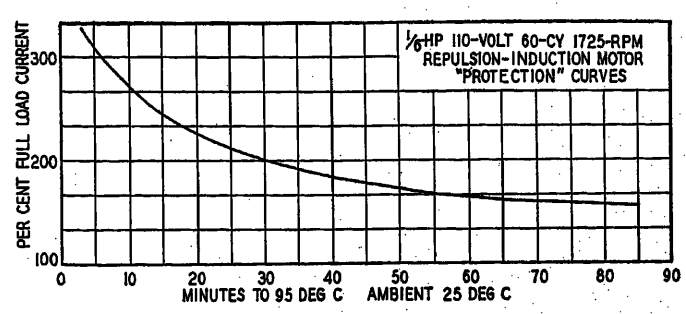

Fig. 1B

A paper recommended for publication by the AIEE committee on general power applications. Manuscript submitted January 4, 1937; released for publication March 1, 1937.

C. W. KUHN is development engineer with Cutler-Hammer, Inc., Milwaukee, Wis.

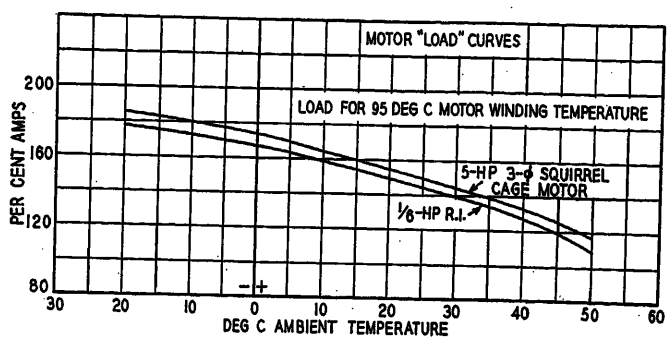

Fig. 2

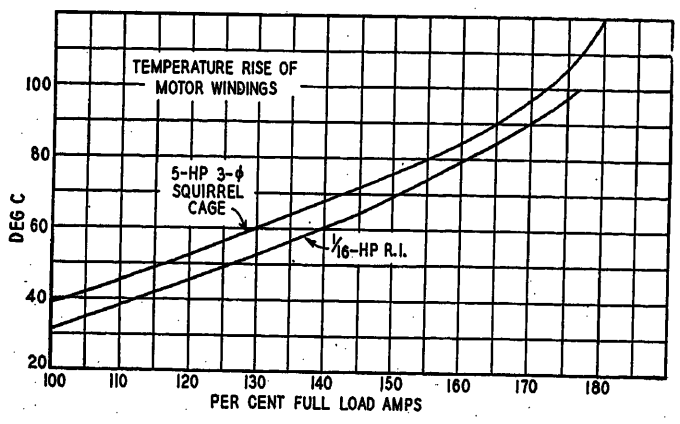

Fig. 3

temperature for various ambient temperatures. Such curves are shown in figure 2 for 2 designs of motors. Data for motor "load" curves can be obtained by determining the temperature rise of the motor winding for continuous operation at different loads as shown in figure 3. The permissible temperature rise at any ambient temperature is the difference between the selected maximum safe temperature and the ambient temperature considered.

## Calculating Motor Temperature Curve

In the absence of actual test data, an investigation for determining motor protection can be made from the usual motor performance curves as shown in figures 4*A* and 4*B*. From these curves a "temperature rise" curve for continuous duty standard motors can be calculated on the basis of a 40 degree centigrade rise of the motor windings at full load. The current and watt loss causing this temperature rise can be obtained from the efficiency and current curves of the motor. The approximate temperature rise at higher current loading is proportional to the watt loss in the motor. A "temperature rise" curve calculated on this basis is shown in comparison with an actual test curve for the same motor in figure 5. From these data we can determine a motor "load" curve as previously explained.

## Thermal Overload Relay Characteristics

Two important thermal overload relay characteristics for motor protection are:

1. "Tripping time" curve
2. "Tripping current" curve

The "tripping time" curve for a thermal overload relay shows the time required to trip the relay at various current values, in an ambient temperature of 25 degrees centigrade. One convenient method of varying the performance of the simple industrial thermal overload relay in this respect is by changes in heater coil design. Curves of figure 6 illustrate some possibilities in this respect. Curve *A* is suitable for the protection of most standard types of motors. Curve *B* shows the performance of a special fast tripping heater coil for the protection of the internal start type of motor. Curve *C* shows the performance of a special slow tripping heater coil for use with the more rugged types of motors with high-inertia starting loads.

To provide thermal overload relays whose operating characteristics more closely follow motor characteristics, designs can be used with additional heat-storage mass to assimilate the effect of the motor frame. Such designs, however, are not generally used for industrial or small-motor applications, their added cost being justified only on large generators and motors.

The "tripping current" of a thermal overload relay depends upon the ambient temperature in which it is operating. This is illustrated by the curves of figure 7. These further show a difference in the effect of ambient temperature as a result of different tripping temperatures of the thermal overload relays. For an ideal thermal overload relay design the tripping temperature should be

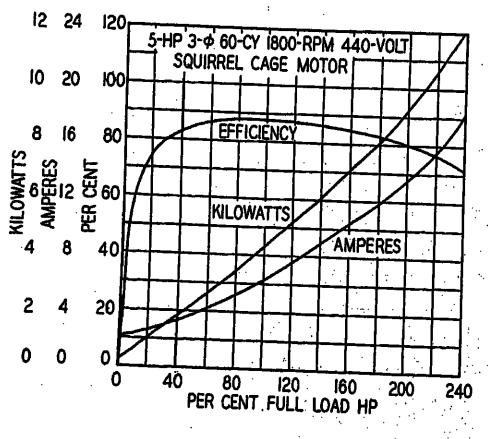

Fig. 4A

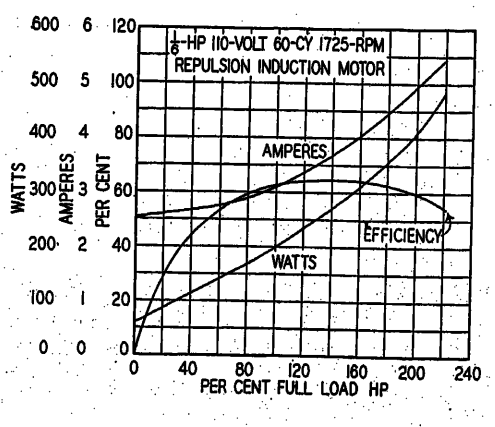

Fig. 4B

such that ambient temperature will change the tripping current to maintain a maximum, safe motor temperature.

The current rating of a thermal overload relay as established by the Underwriters Laboratories requires that it *must* trip at rated current in a 40 degree centigrade ambient temperature. Any manufacturing variation must be such as to cause it to trip at a value below its rated current.

## Thermal Overload Relays

There are 2 general types of thermal overload relays used for industrial applications, i.e., bimetal and solder film. Each of these is manufactured in a variety of ingenious mechanisms. Similar performance can be obtained with either type, as to tripping temperature, time characteristics, etc. Either type can be made with or without current adjustment.

The solder-film type of overload relay is capable of current adjustment by movement of the thermal member with respect to the overload heater. The amount of current adjustment obtainable by this method is limited to approximately 20 per cent. A relay of this type is shown in figure 8. Another method of obtaining current adjustment with this type of thermal overload relay is by use of current transformers with variable taps and adjustment of the magnetic circuit.

Current adjustment is most readily accomplished with a bimetal overload relay by changing the movement (which changes the tripping temperature) required for the bimetal to trip the overload relay. An adjustable thermal overload relay of this type is shown in figure 9.

The chief advantage of the adjustable overload relay is the possibility of its use for motors of different current ratings. Current adjustment is unnecessary on a particular motor application. If the overload rating is proper for that motor, higher current adjustments are dangerous from the standpoint of motor burnout, and lower adjustments are unnecessary for motor protection. Two manual a-c starters with nonadjustable thermal overload units of the solder-film type are shown in figure 10.

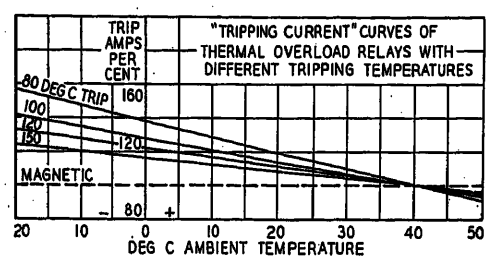

Fig. 7

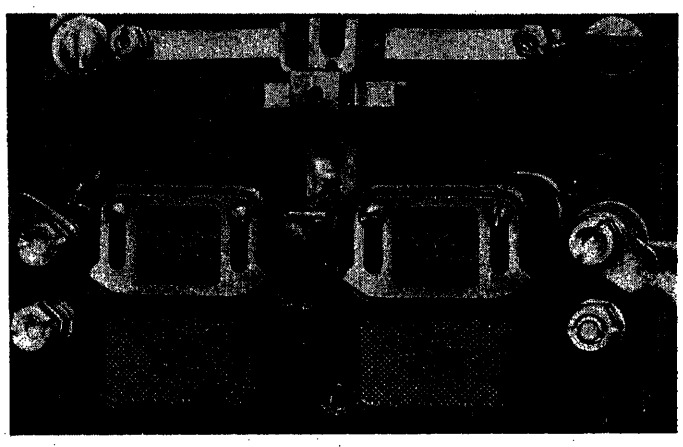

Fig. 8. Adjustable solder-film thermal overload relay (Cutler-Hammer)

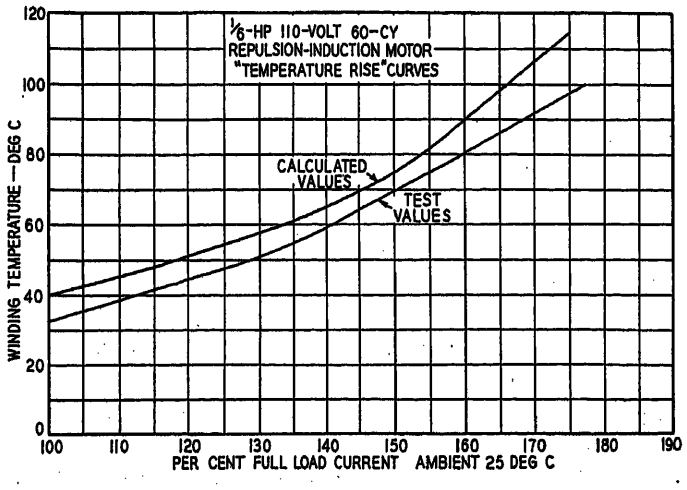

Fig. 5

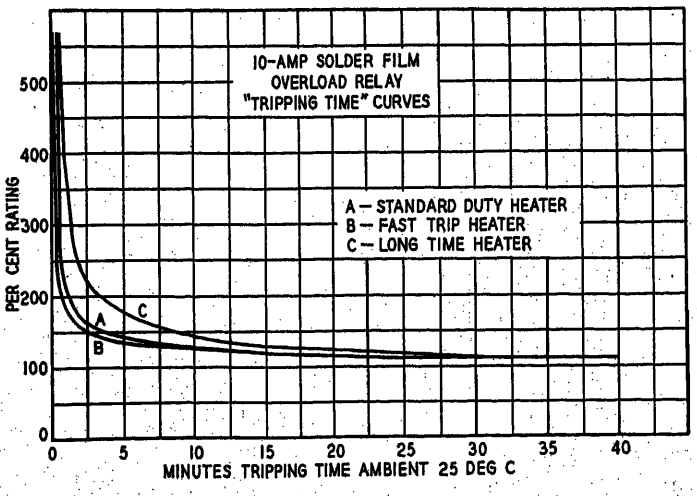

Fig. 6

## Motor-Mounted Overload Devices

Overload devices built into the motor are at present receiving increased consideration, particularly in the small-motor field. These devices are of the same general type as the separately mounted overload units and should be distinguished from those operating primarily from motor temperature. They differ, of course, in detail of construction to meet space and mounting conditions. In general, they incorporate separate heaters for adequate motor protection under locked-rotor conditions. In some designs they are heated by the current which flows

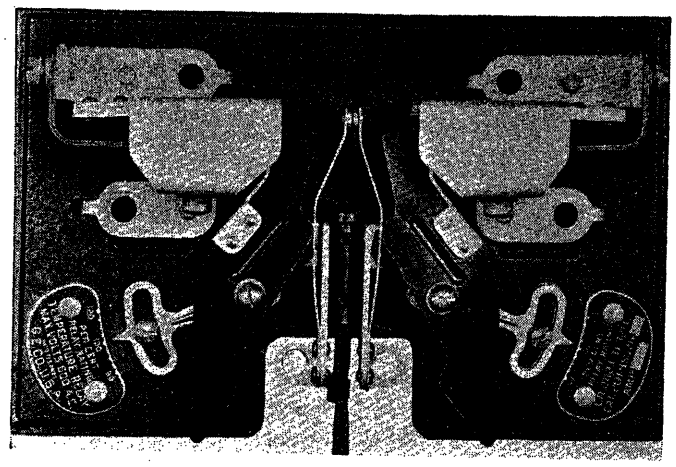

**Fig. 9. Adjustable bimetal thermal overload relay (General Electric)**

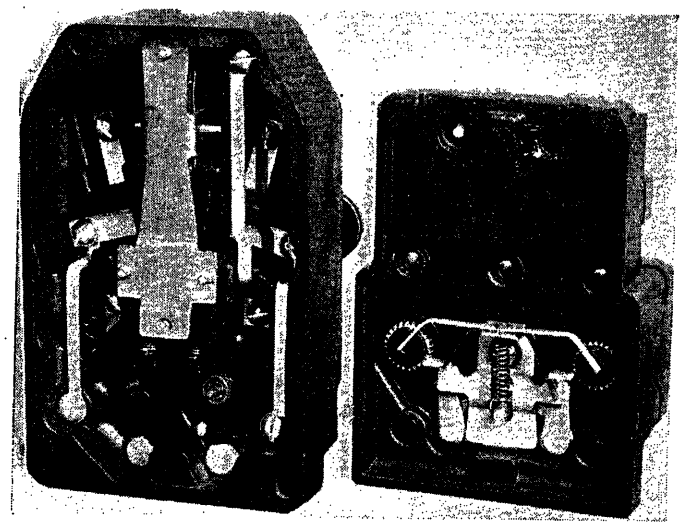

**Fig. 10. Manual starters with nonadjustable solder-film thermal overload units (left, Cutler-Hammer; right, General Electric)**

through the overload mechanism or the bimetal operating strip.

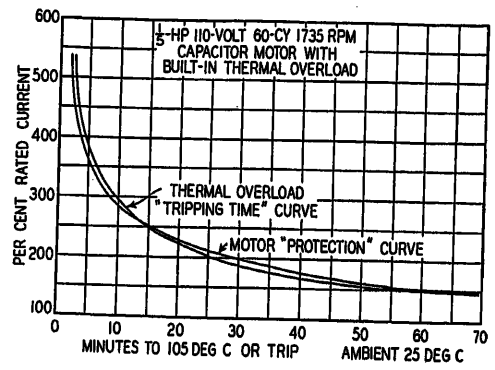
The performance of a thermal overload device built into a motor differs from that of a separately mounted overload unit. Its tripping current is obviously influenced by motor temperature. Consequently, the time characteristics of such an overload device more closely approximate those of the motor, and greater capacity is obtained for carrying short time, heavy overloads. Figure 11 shows motor "protection" and thermal overload relay "tripping time" curves for a solder-film overload relay mounted in the end bell of a capacitor-start motor.

Such motor-mounted overload devices do not, however, follow motor characteristics as closely with variations in ambient temperature. If the motor were to reach the same maximum safe temperature under all conditions, the temperature surrounding the overload would tend to remain constant and the tripping current would be constant. Obviously such conditions cannot be obtained inasmuch as the motor requires materially increased current at lower ambient temperatures for a given maximum safe motor temperature. Therefore, the motor will tend to run cooler at normal ambient temperatures if adequately protected at maximum ambient temperature by a built-in overload device.

## Cycling Overload

The "cycling overload" is an automatic resetting thermal overload device. The contacts are placed in the line circuit to the motor. When it trips, the motor is de-energized. When it resets, the motor again attempts to start. This type of motor protection is only used commercially for fractional-horsepower motors. Its principal application is on motors for refrigeration. Such motor protection is not a new development in this field although its use has recently become more widespread.

**Fig. 11**



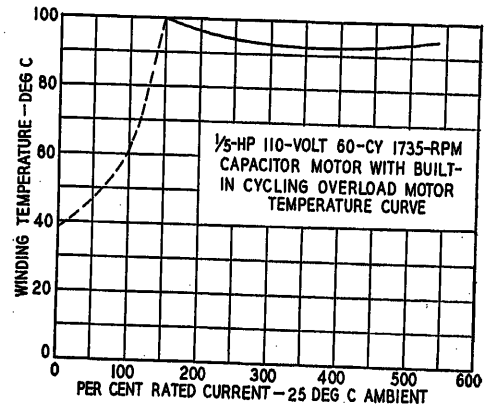


**Fig. 12**

The use of "cycling overloads" for domestic refrigerators has 2 advantages over the manually reset type of overload protection. It permits the use of a smaller motor for starting a refrigerator which has been out of service in warm weather by stopping the motor periodically. This first starting, after being out of service, requires considerably more power than that required to cycle the refrigerator after it has reached normal operating temperatures. The other advantage is that it will restart the refrigerator after a shutdown due to such temporary conditions as, low voltage during a storm, which may cause the refrigerator motor to stall and the overload device to trip.

The "cycling overload" like any other can be used either as a separately mounted device or it can be built into the motor. Figure 12 shows motor temperatures for continuous cycling on overload at various heavy overloads including locked rotor conditions.

## Determining Motor Protection

Motor overload protection can be determined by a comparison of the proper motor and thermal overload relay data. For industrial control applications the following considerations are important.

1. The tripping time of the thermal overload relay should be less than the time required for the motor to reach a dangerous temperature at any load. This can be determined by comparing the "tripping time" curve of the thermal overload relay with the "protection" curves of the motor. The latter should include single phase as well as polyphase operation for polyphase motors.

The thermal overload relay will have a higher rating than the full load rating of the motor for most applications. This overload capacity must be decided upon when comparing "tripping time" and "protection" curves and both considered in common terms of amperes or motor full-load current.

2. Locked-rotor protection can be determined from motor "locked-rotor data" and the "tripping time" curve of the thermal overload relay. The tripping time of the thermal overload relay selected should be less than the time for the motor windings to reach a dangerous temperature. Consideration should be given single-phase performance as well as polyphase performance of polyphase motors.

3. To obtain the best motor protection and to permit operating the motor continuously at maximum safe load, it is generally desirable to have the thermal overload relay installed where it will be subject to the same ambient temperature as the motor. When this relation exists it is an easy matter to determine motor overload protection by comparing the motor "load" curve with the "tripping current" curve of the thermal overload relay. Again this comparison can best be made on a common basis of amperes or per cent motor full-load current.

Installations which require the thermal overload relay to operate at materially different ambient temperatures than the motor should have motor "load" curve and thermal overload relay "tripping current" curves investigated for the corresponding expected ambient temperatures. Complete motor overload protection under such conditions will result in limiting motor capacity below the safe value which would be permitted if both motor and thermal overload relay were installed in the same ambient temperature.

The performance of thermal overload devices built into motors can best be determined by tests of the combined assembly. Such installations are effected by air circulation in the motor and heat conducted from the motor parts to the thermal overload device.

"Cycling overload" applications are likewise best made from actual test data of the combination motor and "cycling overload." An investigation can be made for separately mounted "cycling overload" applications, similar to that outlined for industrial control. It is essential, however, to investigate cycling conditions particularly those for locked rotor. The time the "cycling overload" contacts are closed under such conditions is very short and the motor is energized only a small percentage of the time. A necessary requirement for motor protections is that the "cycling overload" have a smaller "per cent time on" at locked rotor current than the ratio of full-load motor loss watts to locked rotor watts.

Industry is conscious of its a-c motor overload protection problem. This is indicated by the development work being done by both control and motor manufacturers. Perhaps further advancement will be made in the art in the not too distant future.

---

# Survey of Marine Radio Progress

A paper entitled "A Survey of Marine Radio Progress, With Special Reference to R. M. S. 'Queen Mary'" by Commander F. G. Loring, W. L. McPherson, and W. H. McAllister, was read before The Institution of Electrical Engineers in London, England, on March 3, 1937. This 35-page paper, with 29 illustration and tables, gives a general survey of the field of marine radio with a view to placing on record the state of the art as of 1936. A short summary of progress during the past 5 years with particular reference to the nature and volume of traffic, the types of communication involved, and the growing use of direction-finding equipment by navigators is given. Special attention is paid to the types of radio equipment now customarily fitted in cargo vessels and in passenger vessels other than those of the "express steamer" class.

In order to give a description of the problems and how they are met on "express steamer" class of vessels, the R. M. S. "Queen Mary" is used as an example. The actual radio station of this ship and its associated power supply and antenna systems are described. The control room arrangements handle 4 independent duplex circuits which require special precautions to insure efficient multiplex working, quick change of wave length, high-speed transmission and reception, and simultaneous communication on both telephony and telegraphy with both sides of the Atlantic.

With the introduction of subscriber's ship-to-shore radiotelephone service, terminating equipment was required for ship installation. The primary function of the equipment is to prevent local interaction between radio transmitter and receiver, and in addition it may provide a "privacy" system to render speech unintelligible to unauthorized listeners.

On the "Queen Mary" service was planned to be of the same nature as that furnished on the transoceanic radiotelephone links, so that the terminating equipment is more complete than hitherto fitted in ships and includes a privacy system. Communication equipment is housed in 3 separate rooms: the power room, near the engine room of the ship, which contains 2 45-kva alternators (one a spare unit) operated from the d–c supply of the ship; the transmitting room, on the sun deck, which contains the 4 main transmitters and the power control and distribution board; and the operating room, on the sun deck and about 400 feet from the transmitting room, which contains all receivers, telephone terminal equipments, remote-control apparatus, transmitting keys, high-speed transmitting and receiving apparatus, and a complete emergency station. Thirteen antennas are required for transmitting and receiving on various frequencies and for the direction finder.

# Sixty-Cycle Calibration of the 50-Centimeter Sphere Gap

By C. S. SPRAGUE
ASSOCIATE AIEE

G. GOLD.
NONMEMBER AIEE

ONE OF the important functions of the Institute is to provide specifications relating to the standardization of testing equipments and methods. Since the publication of AIEE Standards No. 4, May 1928, considerable progress has been made in the extension and revision of the calibrations for the grounded sphere gap for both 60-cycle and impulse voltages. This paper presents data which should be of assistance in establishing the calibrations of ungrounded sphere gaps. In addition to these data, the paper also describes the equipment and method used in determining the crest voltage applied to the spheres and the means of determining the spacing at spark-over. Data are also presented upon the effect of ultraviolet irradiation of the spheres.

## Summary

1. Ultraviolet radiation of the spheres materially improved the consistency of the sphere gap.

2. As compared with the nonirradiated gap the spark-over spacing of the irradiated gap was slightly but definitely increased over the whole range.

3. The curve of the nonirradiated gap checks the calibration as given in AIEE Standards No. 4 up to approximately 300 kv but falls below standard curve above this point.

4. The vacuum-tube type crest voltmeter used in conjunction with a capacitance potential divider was found to be very satisfactory and convenient both for calibrating the sphere gap and for everyday measurements of 60-cycle crest voltages.

## General Description of Equipment and Setup

The photograph of figure 1 illustrates the spheres, resistors, leads, etc. and the manner in which they were supported. The spheres were of copper, 50 centimeters in diameter, conforming to the AIEE specifications. The shanks were of 3-inch diameter smooth brass tubing, and were 6 feet long. As will be seen from figure 1, each sphere was supported at the shank by 2 pairs of ropes, each pair arranged in the form of a $V$ and fastened to the shank in such a manner as to leave the shank free of loose rope ends, collars, etc. At the upper ends of the $V$ each rope was passed over a small pulley fastened to the wooden frame. The axis of the gap was 12 feet above the concrete floor of the laboratory. With the exception of the shanks, supporting ropes, Uviarc lamp, floor, etc., no other bodies were within 16 feet of the spheres. Individual adjustment of the 8 supporting ropes allowed careful aligning of the gap.

A total series resistance of 2 ohms per volt (effective value) was enclosed in the shields at the ends of the shanks, half of the resistance in the lead to each sphere. The leads from the resistances to the transformer terminals were composed of 3- and 4-inch diameter galvanized iron pipe.

It will be seen that some considerable precautions were taken to eliminate corona formation. In this respect the arrangement was satisfactory as corona became noticeable only at voltages greater than the accepted accurate range of the gap.

The gap spacing was adjusted by pulling back either or both spheres. It may be noted here that the upper ends of the ropes supporting the spheres were so located that there was always tension upon the ropes used to pull back the spheres, thus eliminating all slack or tendency of the spheres to swing. One sphere was provided with a relatively coarse adjustment and the other with a closely controlled continuously variable adjustment. This allowed each sphere to be pulled back approximately the same amount so that the sphere axes would be in line at spark-over.

The sphere spacing at spark-over was measured by means of a telescope, set with its axis perpendicular to the axis of the sphere gap and arranged to slide on carefully aligned ways in a direction parallel to the axis of the sphere gap. A white background shown in figure 1 facilitated accurate setting of the vertical cross hair on the sphere surfaces. The spacings were determined from the readings of a centimeter scale, fixed in position relative to the telescope base. Repeated checks of a given spacing indicated that the error of setting the telescope cross hairs and reading the scale was less than 0.3 millimeter.

Variable voltage for the spheres (up to 600 kv effective center grounded) was provided by 2 135-kva 300-kv (effective) transformers having their primary windings supplied from a tap-changing regulating transformer. Tertiary windings in the transformers were used only to provide a check upon the regulator settings. Each transformer was equipped with a condenser-type high-voltage bushing which was used as the high-voltage condenser of a capacitance potential divider. The capacitance of each bushing was carefully determined over the entire voltage range.

The crest voltage applied to the spheres was measured by means of a vacuum-tube crest voltmeter used in conjunction with the capacitance voltage divider. This crest voltmeter, primarily developed for use in this calibration work, has proved itself to be a reliable and consistent instrument for day-to-day measurement of 60-cycle crest voltages. With conservative operation of the vacuum tubes and other parts, it appears that the instrument re-

A paper recommended for publication by the AIEE committee on instruments and measurements. Manuscript received March 12, 1937; released for publication March 31, 1937.

C. S. SPRAGUE is a research assistant in the engineering experiment station of Purdue University, Lafayette, Ind. G. GOLD is employed by Porcelain Products, Inc., Parkersburg, W. Va.

The writers express their appreciation to Doctor C. F. Harding, head of the school of electrical engineering, Purdue University, for his interest and encouragement in this work.

tains its calibration for an indefinite period. Some other advantageous features of the vacuum-tube crest voltmeter are:

1. Crest voltage readings are obtained independently of wave shape.

2. The crest voltage reading is proportional to the average crest of a number of successive cycles and is unaffected by occasional surges or high-frequency oscillations in the voltage supply.

3. It does not load the capacitance voltage divider, or otherwise affect its ratio.

4. Provides a continuous indication of crest voltage and responds quickly to changes in the crest voltage.

5. Crest voltage readings are to a high degree independent of the supply voltage to the instrument. This is because the operation depends not upon the absolute currents in the vacuum tubes, but rather upon the differential current which is caused to be a function of the applied crest voltage.

The obvious disadvantage of the instrument is that a high-voltage capacitor of known and constant capacitance is required for the potential divider.

The source of ultraviolet radiation was a 220-volt Uviarc operating at approximately 4 amperes and with a drop of 170 volts across the tube. This source was placed 12 feet from the axis of the gap and at the same height above floor level.

## Method of Calibration

The general procedure in determining the relation between voltage and spark-over distance is to assume one of the variables as independent, and to adjust the second until spark-over occurs. The choice usually depends upon the manner and convenience with which the respective factors may be uniformly varied or held constant as the case may be. Thus the spacing may be fixed and the voltage increased to spark-over or the voltage may be set at some desired value and the spacing reduced. The latter method was chosen in this case, since, with the voltage controlled by a tap-changing regulating transformer, this latter method eliminated the possibility of surges or oscillations in the voltage due to sparking at regulator contacts.

In determining the spark-over distance corresponding to a given voltage each sphere was pulled back an equal amount to provide a spacing approximately correct for the voltage used. The sphere with fine adjustment was then pulled back still farther and the voltage applied and set to the desired value. The spacing was then gradually and uniformly reduced until spark-over occurred. The spheres were held at this spacing and the spacing determined by means of the telescope. In this way a large number (10–20) of readings, both with and without ultraviolet irradiation, were taken for each voltage with an average interval of about 3 minutes between readings.

In the first calibration 12 points were taken up to spacings approximately equal to the sphere diameter. A second calibration was then made using 11 intermediate points and later several of the original points were rechecked. The fact that a smooth curve can be drawn through all the points should be reasonable proof of the accuracy of the work and of the consistency of the setup.

Barometer, temperature, and humidity readings were obtained frequently and the final results corrected to a relative air density of unity.

It was quite frequently noticed, when beginning a series of readings after an interval during which the gap had not been sparked over, that the first 2 or 3 spacings obtained were higher than subsequent spacings, in other words, the gap seemed to break down easier. Accordingly from 3 to 6 "clean up" spark-overs were allowed before actually taking data.

With due care, the spacing of the spheres could be reduced very gradually and uniformly with no tendency toward mechanical oscillation or other undesirable motion of the spheres. During this operation the crest voltmeter reading was observed up to the instant of spark-over. Thus, any slight and gradual changes of voltage would be indicated. In general, however, neither the tertiary voltmeter nor the crest voltmeter indicates the presence of short-time surges or high-frequency oscillations which may exist in the power supply system due to external causes, such as switching operations or suddenly changing loads. Occasional erratic readings were obtained and these were

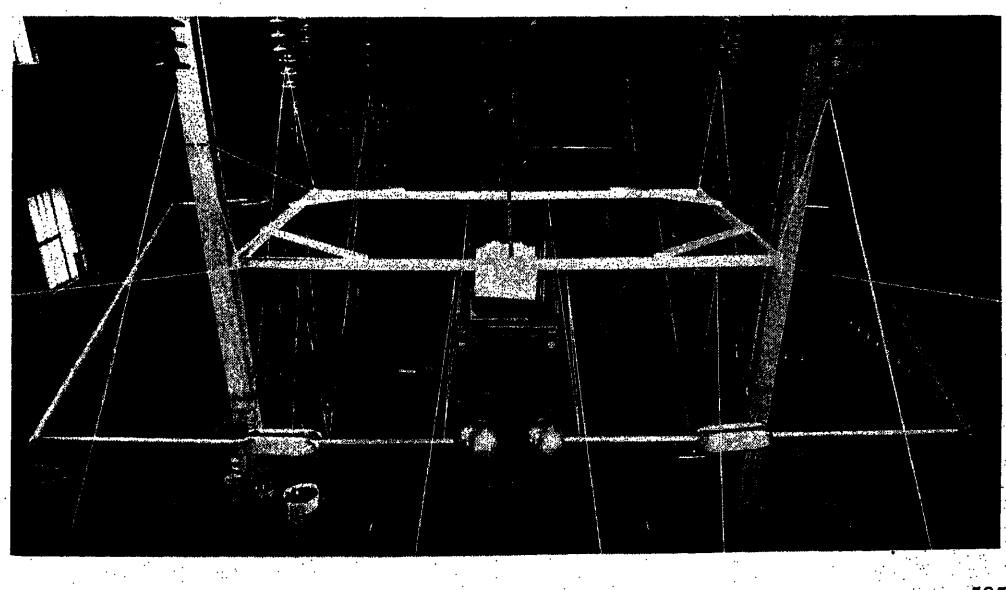

**Fig. 1. Photograph showing arrangement of 50-centimeter ungrounded sphere gap**

attributed to the above factors and were not used in averaging the results.

## Calibration Data

Table I presents the calibration data for the actual test points and is presented principally to illustrate the effect of ultraviolet radiation in decreasing the scattering of individual readings and increasing the spacing.

Table II provides the final calibration data, the values being taken from a smooth curve drawn through the points of table I. Data from the calibration as given in AIEE Standards No. 4 is also provided for comparison.

## Accuracy of Results

As stated before the telescope settings for a given spacing could be repeatedly checked within 0.3 millimeter or within 0.15 millimeter of the average of a large number of readings. There was, however, a second possible error in the measurement of spacing due to a possible change in the angular position of the telescope as it was moved laterally along the parallel ways. Such a change could be caused either by a localized high spot, or by a general and gradual curvature or bowing of the ways. In the former case the high spot might be permanent in which case its effect would be averaged out in drawing the final smooth curve, or the high spot might be caused by loose foreign matter so that its effect would be minimized in averaging a large number of readings for a given point. In the case of a gradual bowing of the ways the error would tend to be of constant percentage. These factors were duly taken into account and considerable care was taken to assure that the motion of the telescope was as nearly truly parallel as possible. It is believed that the maximum possible error is not greater than one millimeter and that the probable error, in consideration of the averaging processes mentioned above, is of the order of 0.5 millimeter.

The accuracy of measurement of the crest voltage depended upon the accuracy of the calibration and of the reading of the crest voltmeter, and on the accuracy of the determination of the ratio of the capacitance voltage divider. The crest voltmeter as mentioned before is not affected by surges and reads the average crest value of a number of cycles. Hence any individual voltage reading might be in error by an undetermined amount depending on the presence and magnitude of any high-frequency surges in the distribution system. Such disturbances were relatively infrequent and it is felt that their ultimate effect was negligible.

The accuracy of calibration and of reading the crest voltmeter were each within $1/4$ of 1 per cent. The ratio of the voltage divider was determined by individual measurements of the capacitance of the condenser-type bushing over the entire voltage range and of the capacitance of the series low-voltage condenser. Except for the extreme upper end of the curve where corona became noticeable, it is believed that this ratio was determined within 1 per cent. Thus the maximum possible error in determining the crest voltages was of the order of $1\frac{1}{2}$ per cent with an estimated probable error of the order of one per cent.

In consideration of the probable errors in determining the spacing and the crest voltage, and of the averaging processes previously mentioned, it may be stated that the final calibration data of table II are accurate to a probable one per cent.

# Probable Outages of Shielded Transmission Lines

By S. K. WALDORF
MEMBER AIEE

## I. Synopsis

Based on the observed phenomenon that flashover of transmission-line towers provided with 2 overhead ground wires occurs only when the product of tower-footing resistance and tower surge current exceeds the insulation strength, the probable outages that will occur on a line can be obtained by a simple method. Only those factors enter into the calculations which have become generally accepted quantitatively.

Computations have been made for 3 transmission lines and the results compared with operating records. The agreement has been very good.

## II. Introduction

SINCE the introduction of the surge-crest ammeter and complementary magnetic links, data have been accumulating which indicate that flashover due to a lightning stroke to a tower occurs only when the product of tower surge current and tower-footing resistance exceeds the insulation strength of the line.[1] If an insulated line conductor is struck, flashover almost invariably occurs. Hence, for a transmission line to be highly resistant to lightning, overhead ground wires are needed to shield the line conductors from direct strokes, and tower footing resistances must be co-ordinated with line insulation.

In order for estimates of line performance to be made in any particular case, several factors must be known quantitatively. These factors are:

1. Degree of shielding of line conductors provided by the overhead ground wires
2. Line insulation strength
3. Tower-footing resistance of every tower of the line
4. Tower surge currents caused by lightning

## III. Evaluation of Factors

At the present time, the art has advanced sufficiently that overhead ground wires can be so placed as to be highly effective in shielding line conductors from lightning.[1,2,3] For evaluating the efficacy of any given arrangement of ground wires and line conductors, scale models can be tested in the laboratory, utilizing an impulse generator.

The second factor to be evaluated is insulation strength, which is much affected by the rapidity of rise and fall of the applied voltage. There is evidence available, though not conclusive, that most lightning strokes cause tower voltages which do not attain their maxima for several microseconds.[5,6,7,8] These data indicate that the impulse strength of line insulation can be taken without serious error as that obtained with the standard $1\frac{1}{2}$ x 40 microsecond wave rather than with the 1 x 5 microsecond one.[9] Due to capacitive-coupling effects between overhead ground wires and line conductors, the strength of insulation installed on a transmission line is greater than that of the insulator strings alone.[10]

The values of ground resistance used for the calculations are those obtained by conventional methods of measurement. The resistance of a tower footing should include only that of the foundation and that of any auxiliary grounding connected to the tower which is in the immediate neighborhood of the tower. The overhead ground wires should be insulated from the tower during measurement.

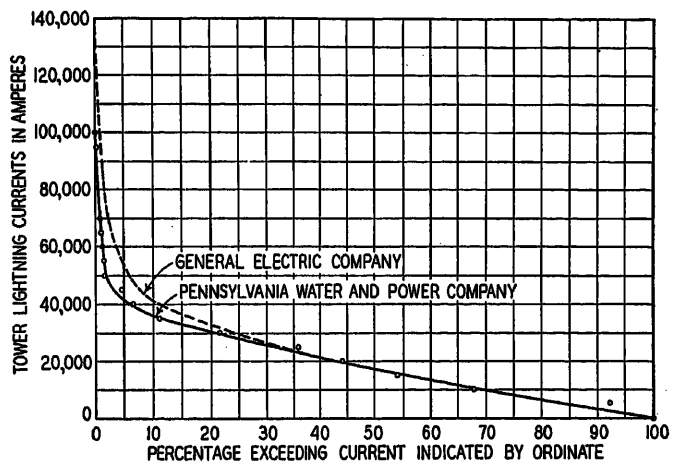

**Fig. 1. Distribution of lightning currents in towers believed struck by lightning**

Observations made with the surge-crest ammeter have shown that tower currents of various intensities produced by lightning occur in a fairly regular manner. The distribution of intensities of current in towers struck by lightning is shown in figure 1. The General Electric Company[1] and Pennsylvania Water and Power Company curves are in relatively close agreement. The tower currents included in the former curve were caused by 358 separate strokes. The data included in the Pennsylvania Water and Power Company curve were obtained during 1934, 1935, and 1936 from 419 strokes. From these curves, the fourth factor needed for calculation can be evaluated.

A paper recommended for publication by the AIEE committee on power transmission and distribution. Manuscript submitted January 13, 1937; released for publication March 6, 1937.

S. K. WALDORF is test engineer for the Pennsylvania Water & Power Company, Baltimore, Md.

## IV. Basis of Probability Calculations

When calculating the number of outages which will probably occur on a transmission line by the method presented here, there are some assumptions made which operating experience has indicated are reasonable. These are:

1. Two overhead ground wires can and will be so provided that any strokes terminating on the line will contact only a tower or overhead ground wire. If the shielding provided is imperfect, strokes to line conductors will nullify any estimates to some extent.

2. Ohmic ground resistance as determined by conventional methods in most cases approximates the footing impedance effective during lightning discharges to a line structure.

3. Flashover occurs on a shielded line only when the product of tower footing resistance and tower crest current exceeds the insulation strength of the line at the struck tower.

4. The insulation strength of the line referred to in 3 is that determined by the conventional $1^1/_2 \times 40$ microsecond wave with electrostatic coupling effects taken into account.

5. Clearance between ground wires and line conductors at midspan is such that the flashover value there is co-ordinated with that at towers.

6. Over a period of time, and with a large number of instances, lightning phenomena and related data are amenable to statistical methods.

7. All sections of a transmission line are equally subject to lightning. If such should not be the case, the line may be divided into sections which meet this requirement.

**Table I—Probability of Outage Data and Calculations Safe Harbor-Westport-Takoma 230-Kv Line**

| Ranges of Tower-Footing Resistance | Towers in Range | | Maximum Safe Tower Current for Towers in Range | Percentage of Tower Currents in Excess of Safe Values | Probability of Flashover |
|---|---|---|---|---|---|
| | Number | Per Cent | | | |
| 0– 5 | 49 | 10.3 | 495,000 | 0 | 0 |
| 6–10 | 141 | 29.6 | 247,500 | 0 | 0 |
| 11–15 | 126 | 26.4 | 165,000 | 0 | 0 |
| 16–20 | 136 | 28.5 | 124,000 | 0.2 | 0.00057 |
| 21–25 | 13 | 2.7 | 99,000 | 0.7 | 0.00019 |
| 26–30 | 5 | 1.1 | 83,000 | 1.5 | 0.00017 |
| 31–35 | 3 | 0.6 | 71,000 | 2.4 | 0.00014 |
| 36–40 | 2 | 0.4 | 62,000 | 3.0 | 0.00012 |
| 41–45 | 1 | 0.2 | 55,000 | 4.5 | 0.00009 |
| 46–50 | 0 | 0.0 | 50,000 | 5.5 | 0 |
| 51–55 | 1 | 0.2 | 45,000 | 7.5 | 0.00015 |
| Totals | 477 | 100.0 | | | 0.00143 |

Flashover voltage of insulator strings (20 5 1/4-inch units) with $1^1/_2 \times 40$ microsecond wave = 1610 kv
Coupling factor for 2 overhead ground wires = 0.35
*Line Data:* (See figure 2)

To illustrate the underlying probability theory, a transmission line of $a$ towers will be considered. Over a period of time, there is one chance in $a$ that any one particular tower will be struck by a particular stroke of lightning. If there should be more than one stroke, the chances are increased in direct proportion.

As flashover is not caused by every stroke terminating on a tower, the critical intensity of the lightning current for a given tower can be found from the following relation:

$$\text{Maximum safe tower current} = \frac{\text{Flashover voltage of insulator strings}}{(\text{1-Coupling factor}) \times \text{Tower footing resistance}}$$

From figure 1, suppose that $b$ *per cent* of the number of strokes $c$ to the line per year are found to cause tower

currents which exceed the critical value calculated for the particular tower considered. Then, the probable number of flashovers which will be experienced by this particular tower is:

$$\frac{1}{a} \times \frac{b}{100} \times c \text{ flashovers per year}$$

If the probable flashovers per year are found for every tower of the line, and then summarized, the probable flashovers per year for the entire line will be obtained.

**Table II—Grounding Data, Safe Harbor-Perryville 132-Kv Line and Holtwood-York 69-Kv Line**

| Ranges of Tower Footing Resistance | Towers in Range | | | |
|---|---|---|---|---|
| | Safe Harbor-Perryville | | Holtwood-York | |
| | Number | Per Cent | Number | Per Cent |
| 0– 5 | 24 | 13.4 | 36 | 20.4 |
| 6–10 | 70 | 39.1 | 87 | 49.1 |
| 11–15 | 48 | 26.8 | 41 | 23.2 |
| 16–20 | 34 | 19.0 | 13 | 7.3 |
| 21–25 | 2 | 1.1 | 0 | 0 |
| 26–30 | 1 | 0.6 | 0 | 0 |
| Totals | 179 | 100.0 | 177 | 100.0 |

As shown later, the calculation need not be made for each tower of a line, but only for groups arranged according to tower footing resistances.

## V. Typical Application of Method

The probable outages that will be experienced on the Safe Harbor-Westport-Takoma 230-kv line[11,12] have been calculated by the method just outlined. The procedure followed will be given in detail.

*Sample Calculation:* (See table I)

$$\text{Maximum safe tower potential} = \frac{1610}{(1 - 0.35)} = \frac{1610}{0.65} = 2{,}475 \text{ kv}$$

$$\text{Maximum safe current for towers of 21–25 ohm range} = \frac{2475}{25} = 99{,}000 \text{ amperes}$$

From the upper curve of figure 1, approximately 0.7 per cent of measured tower currents exceed 99,000 amperes. Also, from table I it is found that 2.7 per cent of the towers comprising the line have footing resistances in the 21–25-ohm range.

Therefore, probability of outage due to towers in 21–25-ohm range = 0.027 × 0.007 = 0.00019. The probability for the entire line is the sum of those for the towers in the individual ranges.

Hence, probability of outage for entire line = 0.00143. Lightning current observations have indicated 115 strokes to this line in 1935 and 108 in 1936, or an average of 112 strokes to the line per year.

Probable outages per year = 112 × 0.00143 = 0.16. This is equivalent to one probable outage in 6 or 7 years.

The method can be used for estimating the performance of projected transmission lines or of existing lines for which improvements are comtemplated. This was done for the Holtwood-York line described in section VI before improvements in lightning protection were installed, and the result obtained was not greatly different from that reported in section VI. The principal difficulty in applying the calculation in such cases is estimating the tower footing resistances which will be obtained. The best approach to the solution of this difficulty is the analysis of data obtained on lines situated in territory comparable to that of the line considered.

**Table III—General Line Data, Safe Harbor-Perryville 132-Kv Line and Holtwood-York 69-Kv Line**

| | Safe Harbor-Perryville | Holtwood-York |
|---|---|---|
| Length (miles) | 31.5 | 22.8 |
| Insulator size | 5¼ inches | 4¾ inches |
| Insulators in suspension | 12 | 8 |
| 1½ x 40 microsecond flashover | 1,025 kv | 675 kv |
| Average strokes to line per year | 48 | 31 |

## VI. Calculated Performance and Operating Experience

The test of any method of estimating the probable performance of transmission lines during lightning seasons must necessarily be the operating records. At this time it is possible to give such a comparison of estimated and actual performance for three transmission lines over various periods of time. Although the operating period is relatively short in each case for any conclusions to be drawn, the results thus far are believed to be significant.

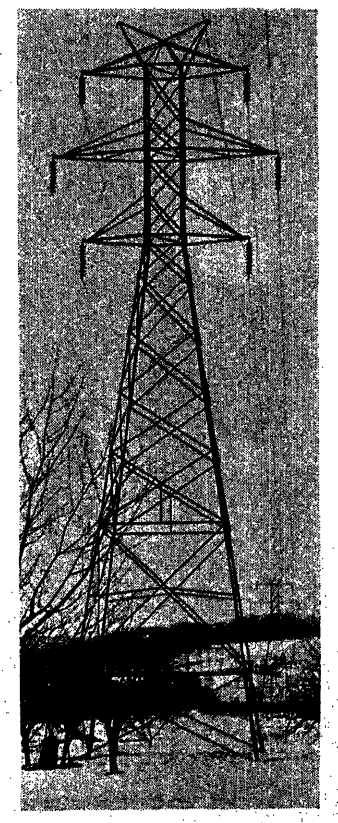

**Fig. 5. Double-circuit, vertical configuration, suspension tower of the Holtwood-York 69-kv line**

Present appearance, with 2 overhead ground wires installed

As shown in section V, calculations indicate that over a period of time there should be about one outage of the Safe Harbor-Westport-Takoma 230-kv line every 6 or 7 years. This line has actually been in service for only 5 years, during which time one outage occurred.

In figure 3, is shown a tower of the Safe Harbor-Perryville 132-kv line which supplies energy to the electrified section of the Pennsylvania Railroad between Washington and Perryville. This line has been in operation through the lightning seasons of 1935 and 1936 without any outage occurring, even though the surge crest ammeter links indicated 27 strokes to the line in 1935, and 69 in 1936. In tables II and III are given data for this line. Calculations indicate that there will probably be one outage every 4 years over a period of years.

Table IV—Actual and Probable Outages of 3 Transmission Lines

| Line | Years of Operation | Lightning Outages per Year | |
|---|---|---|---|
| | | Actual | Probable |
| Safe Harbor-Westport-Takoma | 5 | 0.20 | 0.16 |
| Safe Harbor-Perryville | 2 | 0 | 0.27 |
| Holtwood-York (improved) | 1¼ | 0 | 0.38 |

The Holtwood-York 69-kv line until 1935 operated without any overhead ground wire or auxiliary grounding. The appearance of the line at that time is shown in figure 4. By August 1935, 2 continuous counterpoises[13] and 2 overhead ground wires were installed which eliminated all flashovers in the subsequent period through 1936 (about 1¼ lightning seasons). The present appearance of the line is shown in figure 5. Line data are given in tables II and III. Calculation shows that one outage in about 3 years can be expected on this line.

## VII. Summary

Data have been accumulating which permit the computation by a simple method of the probable lightning outages of a transmission line protected by overhead ground wires. Only those factors enter into the calculations which have become generally accepted quantitatively.

The results of computation and the operating record of 3 transmission lines are compared in table IV.

The agreement of results of computation and experience, and the simplicity of the method warrant its use for estimating the probable lightning performance of shielded transmission lines over a period of years.

## Calibration of the 50-Centimeter Sphere Gap

(*Continued from page 596*)

has a decidedly beneficial effect in reducing the scattering of individual readings.

If ultraviolet light is to be used with sphere gaps, the gap calibration should be determined under the irradiated condition. Although no tests were made in this work using varying intensities of irradiation, it seems probable that the calibration and use of the irradiated sphere gap should be, for the greatest accuracy, specified for a particular range of radiation intensities.

The results of this investigation indicate that, for non-irradiated spheres, the previous calibration gives crest voltages which, in the range above 250 kv, are from 2 to 12 kv too high. For the irradiated spheres the previous calibration appears to be in error by a still greater amount, and gives voltages which are too high over the entire range.

# Discussions

## Of AIEE Papers—as Recommended for Publication by Technical Committees

ON this and the following 33 pages appear discussions submitted for publication, and approved by the technical committees, on papers presented at the sessions on electrophysics, electrical machinery, induction machinery, power transmission, and tensor analysis at the 1937 AIEE winter convention, New York, N. Y., January 25–29. Authors' closures, where they have been submitted, will be found at the end of the discussion on their respective papers.

Members anywhere are encouraged to submit written discussion of any paper published in ELECTRICAL ENGINEERING, which discussion will be reviewed by the proper technical committee and considered for possible publication in a subsequent issue. Discussions of papers scheduled for presentation at any AIEE meeting or convention will be closed 2 weeks after presentation. Discussions should be (1) concise; (2) restricted to the subject of the paper or papers under consideration; and (3) typewritten and submitted in triplicate to C. S. Rich, secretary, technical program committee, AIEE headquarters, 33 West 39th Street, New York, N. Y.

## Expansion Theorems for Ladder Networks

**Discussion and authors' closure of a paper by Michel G. Malti and S. E. Warschawski published in the January 1937 issue, pages 153–8 and 152, and presented for oral discussion at the electrophysics session of the winter convention, New York, N. Y., January 28, 1937.**

J. J. Smith (General Electric Company, Schenectady, N. Y.): This paper gives a systematic method of finding the currents and voltages in ladder networks under steady-state conditions. The usual method for such problems has been to find a general solution containing unknown constants and then evaluate these by satisfying certain boundary conditions. While this is readily done for the simpler types of networks, the determination of these constants corresponding to a given physical problem is often a difficult one for more complicated networks. For such cases the solutions given in equations 24*a* and 24*b* supply a direct method of obtaining the result.

It would appear desirable to make it clear at the outset of the paper that these solutions apply only to steady-state conditions since this is not apparent now until one has followed through the work. I wonder if the authors have made any further studies with regard to the extension of their solution to transient conditions.

The problem solved by the authors is of the type Heaviside refers to as "given the cause, find the effect" since they assume a certain network and derive its admittance at a given frequency. In his paper last year Malti showed how the method he followed was also directly applicable to the inverse of the Heaviside expansion theorem since such problems do not require the solution of the complex integral corresponding to equation 6. The inverse problem of the type "given the effect, find the cause" is also of interest since in this case we are given the admittance we desire at various frequencies and wish to find a physical network which will have such characteristics. I should like to inquire if the authors have looked into the possibilities of applying their method to this type of problem.

M. G. Malti: Smith raised 2 important questions which I shall answer separately.

*a*. We are now engaged in preparing a paper covering the extension of this work to the transient state. We hope to publish this paper at some future date.

*b*. The inverse problem (given the cause, required the effect) is extremely involved. We hope to undertake this problem after we have worked out some of the comparatively more simple cases.

## Abrasion—A Factor in Electrical Brush Wear

**Discussion and author's closure of a paper by V. P. Hessler published in the January 1937 issue, pages 8–12 and 16, and presented for oral discussion at the electrical machinery session of the winter convention, New York, N. Y., January 28, 1937.**

M. S. Coover (Iowa State College, Ames): The research investigations on electrical brush wear that are being conducted under the direction of Hessler have served to bring to light some significant fundamental information on the subject. Anyone even superficially familiar with the phenomena of sliding electrical contacts is aware of the many variables that are not only simultaneously present in the normal operating cycles of machines from time to time, but that they are probably difficult to separate and evaluate positively in a research of any kind. Only by eliminating as many of the variables as possible and attempting to control those elements that the investigator chooses to retain can anything like dependable data be procured. The information submitted indicates that Hessler has a good understanding of the problems involved and that he has made a logical approach to them.

The photomicrographs of ring surfaces show a striking contrast between the paths produced by graphite anode and graphite cathode brushes. It seems clear that these photomicrographs give rather convincing evidence that the more rapid wear of the graphite cathode brush is produced by a ring surface condition most likely attributable to the ionization of the ring material.

The test data indicate that brush wear is caused largely by abrasion. It is interesting to discover from the information in figure 11 that the trailing metallic brush without current actually wore more rapidly than the leading metallic brush did with current. This is quite the opposite from the experience with graphite brushes. Since the author has so advantageously made use of photomicrographs to explain at least in part the action of wear in the case of carbon or graphite brushes, it suggests that possibly the same procedure might be employed for metallic brushes. Hessler does not present such photomicrographs in his paper, nor does he make reference to them. Perhaps he intends to bring out this point later.

The writer believes that the test data plotted in figure 8 and figure 9 give some quantitative idea of the breakdown of total wear into its principal components, namely, mechanical brush wear, and electrical brush wear, although no information has been included on the current densities used. It would be instructive to make comparison of these data with observations using zero current on all four brushes, other conditions remaining the same.

It is hoped that this important study can be carried further. Certainly, the new information justifies it. A better understanding of the phenomena that take place with moving electrical contacts would be of inestimable value to both designer and operator.

R. M. Baker (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): Hessler has shown in a very interesting manner the large effect of abrasion on brush wear and an extension of this investigation to include operation with different gases, different brush grades and different ring material should not only help a great deal in explaining the whole process of brush wear but should also be of great value in assisting the design engineer in the choice of brushes for various applications.

It has been generally realized that the smoothness of the brush track affects brush wear, for brushes often wear much more rapidly just after the ring surfaces have

been freshly turned or stoned than later, after the rings have become polished in operation. It has not been realized generally, however, that abrasiveness could be produced in a brush track by current-carrying brushes, so that a currentless brush running in this same track would wear almost as rapidly as the brushes which carry current.

There is a seeming contradication to the findings of this paper which will be described. If a number of brushes operate in parallel on a slip ring and one of these brushes voluntarily drops its current, this brush simultaneously ceases to wear. This condition is probably brought about either by some inhomogeneity in the brush or more likely by some foreign material being picked up from the ring surface. This not only would cause the brush to drop its current but would also cause it to stop wearing. Thus one might reconcile the experience with brushes operating in parallel and having poor current division with the results of Hessler's paper.

The writer must raise a question regarding conclusion 2 of this paper. A great deal of testing experience has shown the polarity effect to be in agreement with what the author finds for carbon brushes, but opposed to what he finds for metal graphite brushes. Using his nomenclature, it is always the cathode brushes which have been found by the writer to wear most rapidly. This polarity also shows many times as much ring wear as the other polarity. The discrepency may be due to the high absolute humidity maintained by Hessler in his experiments. The moisture content (14 grains per cubic foot) is about double what one finds on the average warm summer day. The high ambient temperature may also have some effect but the ring temperature probably does not rise much above the ambient due to the small electrical and mechanical losses in the contacts. The high humidity may also account in part for the large difference in brush wear at the two polarities when the brushes are not tracking. Some of the author's own data (reference 2 in paper) indicates this fact.

**M. S. May** (Speer Carbon Company, Saint Marys, Pa.): Hessler is to be congratulated on his article for the large number of readings which he has apparently made and for the new ideas brought out relative to brush wear. It was formerly thought that some mysterious "electrolytic action" caused the increased brush wear when current was flowing as compared with that under no-load conditions. Hessler has shown that this difference is due to some roughening of the commutator by current with a resulting abrasion of the brush material. It is unfortunate, however, that the test could not have been of greater duration between individual readings as 24 hours is a very short period on which to base results of brush wear.

One point brought out by Hessler was of particular interest to me. In his present paper as well as his earlier one presented a year ago, he shows that the anode brush wears faster than the cathode in case of metal grades and that the cathode wears faster than the anode with the electrographite or carbon grades. This condition prevails whether the anode and cathode

Table I

| Grade | Type | At 100 Amperes Per Square Inch: Wear per 1,000 Hours | At 100 Amperes Per Square Inch: Watts at Surface |
|---|---|---|---|
| *A* | Electrographite | 10 | 112 |
| *B* | Electrographite | 10 | 100 |
| *C* | Carbon-graphite | 16 | 82 |
| *D* | Carbon-graphite | 16 | 75 |
| *E* | Metal-graphite | 38 | 11 |
| *F* | Metal-graphite | 44 | 16 |
| *G* | Metal-graphite | 38 | 12 |

brushes run on individual tracks or in the same tracks. To my knowledge, there is no satisfactory explanation of this condition. It appears possible that the metal may be carried with the current to a degree sufficient to reverse the condition that prevails with the non-metal grade. This would be going back to the electrolytic theory and I would appreciate Hessler's comments.

Hessler's statement that brush wear is due primarily to abrasion is borne out by the following data tabulated from his article and indicating the brush wear is least in the grades having the maximum amount of electrical energy dissipated at the brush surfaces.

But if we assume that the abrasion is due to roughening of the ring by the current, we still have to explain why the roughening and brush wear are in inverse ratio to the wattage dissipated and bear no relation to the amperage carried.

Tests conducted over long periods on slip rings using a-c current and brushes of standard rotary-converter size indicate that other factors are involved than those discussed by Hessler. For example, a hard, heavy metal brush may wear the ring considerably more but show a lower rate of brush wear than another metal grade run under identical conditions. In this case, the brush which runs on the rougher ring shows the lower rate of wear, apparently due to properties of the brush itself.

Hessler's comments on the use of metal and nonmetal brushes on the same ring, call to mind the troubles encountered occasionally in winter on rotaries and attributed to high friction resulting from low humidity. These manifest themselves in very rapid brush wear. We have had some success in such conditions by using one pure graphite brush on each ring to supply lubricant to the metal brushes which carry the load.

There is one point that I believe should be brought out in considering Hessler's reports. The abrasion action mentioned by him as causing brush wear is not to be confused with the abrasive action discussed in brush catalogs and by brush salesmen. This latter is a characteristic of the brush itself due to the presence of hard mineral or carbon particles in the brush material. It is desirable under certain conditions to use such an abrasive brush to assist in keeping clean the ring or commutator surface or to wear down the mica where it is not undercut. It will generally be observed that an abrasive brush has a shorter life than a non-abrasive one, other things being equal, and in this respect, abrasion built into a brush has the same net result as that considered by Hessler.

**R. E. Hellmund** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): Various investigators of contact phenomena are all in agreement that the oxide film forming on the slip rings in air is an important factor. A great deal of evidence has been submitted to substantiate this point of view and some additional evidence is contained in the papers presented today. However, it is difficult to explain the difference in behavior of various grades of carbons and ring materials by the oxide film formation alone. Some investigators offer in explanation of some of the differences found the presence of varying amounts of abrasive material in the carbons, and the specific resistance of the carbon material is, of course, also considered of influence. I have always felt that in addition to these factors, certain loose graphite particles may have some influence on contact resistance. (See "Sparking under the Brushes of Commutator Machines," R. E. Hellmund and L. R. Ludwig, ELECTRICAL ENGINEERING, March 1935, page 315, and my discussion of paper "Sliding Contacts—Electrical Characteristics," by R. M. Baker, ELECTRICAL ENGINEERING, July 1936, page 821.) It is rather surprising to me that this point of view has not been accepted by various investigators at least to the extent of making investigations along this line, particularly in view of the fact that they make reference to the loose graphite particles in their investigations of brush and ring wear. In an article on the subject, "Brush Wear in Hydrogen and in Air," *Electric Journal*, June 1936, page 287, Baker has advanced what appears to be a plausible explanation of certain phenomena observed in connection with the wear of brushes. In this article it is assumed that the high temperatures prevailing near certain spots of the carbon surface tend to loosen some graphite particles by the oxidation of the binding material that takes place in the presence of oxygen. Regardless of how these graphite particles become loose, there is no doubt of their presence because they can frequently be observed in practice. It would therefore seem expedient to investigate any possible influence they may have on the contact resistance.

Figure 1*A* shows the ring, brush, and oxide film and it is assumed that at *a* the oxide film has been punctured. If, as a result of this, current passes from the brush to the ring or from the ring to the brush, the highest brush temperatures will exist in this neighborhood and it is quite likely that graphite particles 1, 2, and 3 will become loose. If this occurs any appreciable distance from the edges of the brush, any theory must take into account the subsequent location and behavior of these particles. It they happen to be located in the puncture of the film as indicated in figure 1*A* they are bound to participate in current conduction and therefore will probably influence the contact resistance until they are disposed of, either by burning up or by being removed from under the brush. It is difficult to imagine that all of these particles will remain within the puncture; it is more likely that at least some of them will be carried along and thus may enter between the oxide film and the brush, as indicated by particles 4, 5, and 6 in figure 1*B*. If this condition prevails, which it is likely to do under the negative brush where as a rule

the greatest amount of brush wear takes place, the separation of the brush from the oxide film by the particles as shown in figure 1*B* would no doubt have some influence on the contact resistance and might lead to irregularities and sparking under the brush. It is not impossible that the irregularities in the contact voltage shown in figure 2*C* of the paper by Baker and Hewitt can be explained in this manner. Another possibility which should be considered is that the graphite particles are harder than the oxide film and therefore may be forced into the film as shown in figure 1*C*. Under

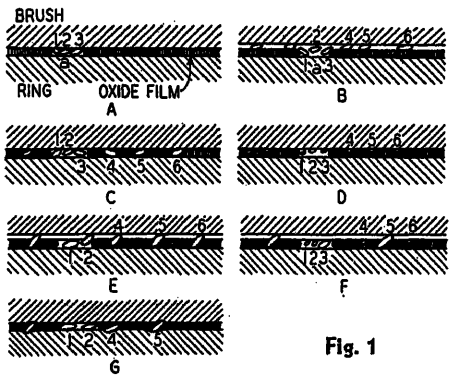

Fig. 1

this condition it is evident that these particles may form conducting bridges between the brush and the ring, and it is possible that the change in contact resistance observed with increasing current density may be caused largely by an increased number of particles acting as conducting bridges. However, the extremely short time required for decreasing the contact resistance when the current is increased suddenly, makes this possibility somewhat doubtful. It would further have to be assumed that when the current is interrupted these particles will gradually fall out thus permitting the oxide film to reform. This latter assumption is not at all contrary to observed data such as given in the papers presented.

By assuming that these loose particles have a bearing on the contact phenomena, it would seem relatively easy to explain the differences observed even in carbons having the same electric conductivity. A mere comparison of figures 1*D*, *E*, and *F*, under the assumption of relatively small particles of equal size in figure 1*D*, relatively large particles of equal size in figure 1*E*, and a combination of small and large particles in figure *F*, brings out very different conditions of current conduction. If the conditions of figure 1*D* apply, the particles may have little influence upon the contact resistance, while just the opposite might be expected with the large particles of 1*E*. Incidentally, the conditions shown in figure 1, *E* and *F* might explain some of the brush-wear data given in Hessler's paper. Differences might also be expected with the same 3 conditions of particles but under the assumption that the particles are not forced into the oxide film but merely ride on top of it. Another conceivable condition is that the graphite particles penetrate not only the oxide film but also the metal surface to a certain extent and that they lodge in the crevices of the metal ring surface as indicated in figure 1*G*. This might explain differences which have been observed with different finishes of the metal surfaces as well as differences found between ordinary cast material and other materials having a denser or harder surface structure. Finally, it seems possible that the graphite particles might dent the oxide film and force it into existing crevices of the ring without, however, penetrating it mechanically. In reality, the phenomena are probably even more complicated than indicated by any of the individual figures, as a combination of the various conditions shown in the figures may exist. As suggested in my brief discussion of Hessler's paper on "Electrical Brush Wear" (ELECTRICAL ENGINEERING, April 1936, page 406), the possibility of cuprous (red), low-resistance oxide forming in the neighborhood of the high temperature breakdown points may also enter into the phenomena. The abrasive effect of the ash particles in the carbons, previously referred to, and also the specific resistance of the carbons must as a matter of course be given due consideration.

Regardless of which of these factors are the most important under normal operating conditions, it would seem that the mechanical structure of the carbons as influenced by the number of graphite particles, their size, and the ease with which they become loose, is likely to be responsible for some of the differences observed in the contact resistance when different grades of carbons are operated on the same type of rings and under otherwise identical conditions.

**V. P. Hessler:** The tests of figures 8 and 9 were made at 50 amperes per square inch, of figures 10 and 11 at 120 amperes per square inch, and of figures 12 and 13 at 80 amperes per square inch. This information should have been given in the paper.

Baker's suggestion that the investigations be extended to include the effect of other gases, more brush grades, and other ring materials is in order. As suggested at the close of the paper it would be very instructive to repeat the investigations in the absence of oxygen. Perhaps a series of experiments of a similar nature, but designed to ascertain the conditions which produce electrical wear rather than abrasion would be most instructive. The cathode brush of figure 8 in the paper shows a large ratio of electrical wear to abrasion.

In every experiment performed by the author to date the anode metallic brush has always worn very much more rapidly than the cathode brush, whereas Baker has always observed the opposite effect. An extended conversation with Baker seemed to indicate that the only important variation in operating conditions was a difference in humidity. Some experiments will be performed with the lower humidity at the earliest possible date.

Baker's attempt to reconcile the action of a shirking brush on a slip-ring with the results of the paper illustrates a daily occurrence in a brush laboratory. The results of brush tests seem replete with inconsistencies when viewed from the standpoint of our present knowledge. However, it is hoped that many of these apparent inconsistencies will disappear with a complete understanding of brush phenomena.

Coover suggests that it would be interesting to obtain photomicrographs of metallic brush paths also. Only one of the slip-ring mechanisms was arranged for taking photomicrographs and it so happened that none of the metallic brush tests were made on this mechanism.

It is desirable to make the individual wear tests as long as possible, but whenever one test is extended over a longer period some other test must necessarily be deleted. The 24-hour period seemed to represent the best compromise. Actually some of the tests, in effect, were much longer than 24 hours. In figures 10 and 11 is change which was made in the operating conditions for 8 days.

May's theory that metal may be carried to the ring from the anode metallic brush has been considered as a possible explanation. The writer has planned to operate metallic brushes on a ring of some metal other than copper and study the paths carefully with the aid of microchemistry. The dissimilar metals should simplify the problem of detecting transferred materials. Of course, wear studies will have to be conducted simultaneously to ascertain whether the new material gives brush wear comparable to that with copper.

The tabulation of watts at the contact surface and wear made by Mr. May is very interesting. Previous studies made by the writer on wear indicate that there is no correlation between contact drop and wear, except in the case of a copper impregnated brush. This brush gave very similar wear and contact drop curves.

While the writer does not see any close connection between Hellmund's theory and the wear studies presented in the paper, it does relate to a very interesting observation made several years ago by a graduate student in the writer's laboratory. A very well developed "photograph" or blackened spot, had formed on a ring with a resulting high contact drop. With the hope of ascertaining the film resistance of the "photograph" the ring was stopped with the "photograph" under the brush and voltage-current data obtained. Then the ring was rotated until a normal ring surface was under the brush and the test repeated. The "photograph" showed by far the lower contact resistance and the voltage current characteristic was straight. From this the writer assumed that the black film consisted largely of carbon particles imbedded in the copper itself, but projecting through the oxide film, much as Hellmund has drawn this in figure 1*G*.

## Arc Characteristics

### Applying to Flashing on Commutators

**Discussion and author's closure of a paper by R. E. Hellmund published in the January 1937 issue, pages 107–13, and presented for oral discussion at the electrical machinery session of the winter convention, New York, N. Y., January 28, 1937.**

J. N. Jones (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): The methods and data given in the paper make it possible to answer various

questions regarding flashing, and one practical example may be of interest. Originally most railway motors were operated on full line voltage of 600 volts, but several years ago 2 motors in series were advocated by Westinghouse engineers under certain railway operating conditions in order to improve flashing. It was felt at the time that such improvement would be accomplished by this, but the question could not be analyzed and it required several years of experience to prove the soundness of the proposed change. With the data now available, the analytical answer to this question can be given.

In the accompanying figure, the arc characteristics for 10 to 60 amperes at a

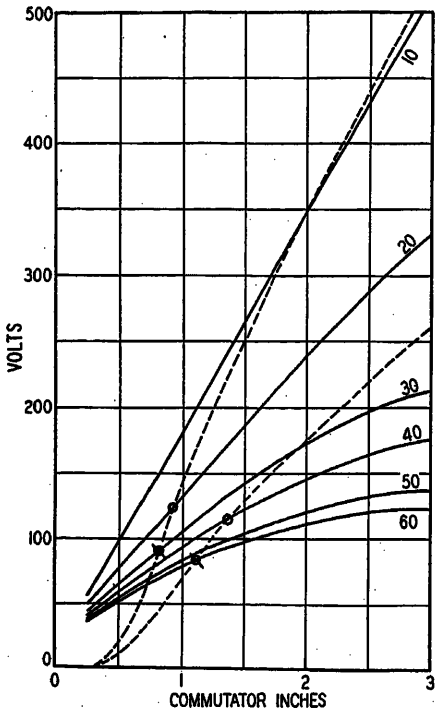

Fig. 1

speed of 2,200 feet per minute are given; the dotted lines indicate the voltage induced around the commutator, the upper curve applying to a 600-volt and the lower to a 300-volt machine. If we select a point of intersection on the 20-ampere curve of the high-voltage motor we find it to be at a distance of 0.93 inch from the zero line. The same motor operated from 300 volts would carry the same load with 40 amperes, and thus we have to find the intersection point for 40 amperes with the lower curve, This point is 1.38 inches from the zero line, which means an increase of 48 per cent and, correspondingly, a reduced tendency to flash. Similarly, the intersections of the 30-ampere curve with the high-voltage curve and of the 60-ampere curve with the low-voltage curve indicate an increase of 41 per cent. Practical experience has demonstrated that 300-volt motors are less subject to flashing in service, a fact which is somewhat in accord with the values indicated in these curves.

By a similar analysis of curves for a higher speed, 3,200 feet per minute, it was found that the distance from the zero line to the point of intersection of the 40-ampere, 300-volt curves was 44 per cent greater than that of the intersection of the 20-ampere, 600-volt curves. By a comparison of the 60-ampere, 300-volt and the 30-ampere, 600-volt points of intersection, the distance from the zero line of the first was 37 per cent greater than that of the latter.

For a speed of 1,100 feet per minute, the distance from the zero line to the 40-ampere, 300-volt point of intersection was found to be 52 per cent greater than that for the 20-ampere, 600-volt intersection. The corresponding distance for the 60-ampere, 300-volt point was found to be greater, by 46 per cent, than that for the 30-ampere, 600-volt.

From the results of these comparisons it would seem: (1) as the speed of the motors increases the advantage of having the motors in the series arrangement becomes slightly less but is still appreciable; (2) as the load becomes greater the advantage of the series connection over that of the full line voltage decreases.

**R. C. Mason** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): Without commenting on the interest and value to engineers of Hellmund's work, I would like to point out how some of his results can be explained in a general way by recent advances in our knowledge of gas discharges.

1. Figures 5 and 6 of Hellmund's paper are a little misleading where they show arc voltage increasing continuously from zero. Actually, as soon as an arc is drawn, a definite arc voltage develops, and the curves should start at that point. Even fairly high-speed cathode-ray oscillograms show that the voltage across a pair of opening contacts suddenly increases from a low contact drop to an arc drop of some 10 or 12 volts.

2. When the current through an arc of constant length decreases, the arc voltage changes in a manner which depends on the speed with which the current reduces: the arc voltage will be lower, the more rapidly the current decreases. In these experiments, however, where an arc is drawn by a moving commutator, an increase in arc length accompanies (causes) the decrease in current. While perhaps the losses from the arc may be influenced because air currents about the arc vary with commutator velocity, it seems that the predominant effect upon the arc voltage when the arc has reached a definite length and current must come from the speed with which the arc has been lengthened. How this may result can be seen by considering 2 extremes: suppose an arc for which the gradient in the positive column is 10 volts per centimeter has its length increased *extremely slowly* by one centimeter, while the current remains constant; the arc voltage will merely increase by 10 volts. If, however, the arc length could be *instantly* increased one centimeter, by the introduction of one centimeter of cold unionized gas, then the arc voltage would increase by the many thousand volts required to break down the one centimeter of cold gas. Of course, the latter extreme is never realized in practical cases of arcs on commutators, but the point is that whenever a new length of positive column is created, the voltage required to maintain any particular current in that length depends upon the temperature and state of ionization of the gas. If the arc lengthens quickly, the temperature and degree of ionization of the gas in the newer parts of the positive column lag behind those of the older parts; hence to maintain the arc, a higher gradient must be applied in the newer than in the older parts. If, however, the arc length increases gradually, the energy lost from the older parts of the positive column has time to flow into the newer parts, and not much increase in gradient arises. Thus, the arc voltage should increase with increased speed of drawing of the arc, just as shown in figure 7.

3. In the experiments described in the last part of the paper, the cathode or anode spots cannot actually move continuously over the commutator, because of the insulation between bars. Hence for advancement, new arc terminals must form. It is well known that a new cathode spot will not be established unless the electrode is at a potential considerably negative with respect to the adjacent arc stream, but it is perhaps not generally appreciated that likewise a new anode terminal will not form until the electrode is several volts positive. Figure 12*A* illustrates this very well; on the right side, no current flowed to the first bar from the shorted sector, the arc anode transferring directly to the second bar. In this case, it was necessary for the new electrode to be at least some 15 or 20 volts positive with respect to the adjacent positive column in order for the new anode to strike. The commutator bars are cold, while the gas in the arc column is at some 5,000 degrees or 6,000 degrees, so no matter how closely the arc stream hugs the commutator, always a transition region exists in which the gas temperature falls from the high value of the arc to the low temperature of the metal. Through reduction of electron mobility within the cold gas, the flow of current is so impeded that considerable voltage must be applied across this region in order to carry the full arc current and establish a new anode spot.

At a new cathode spot additional requirements, not well understood, must be met which demand even a higher voltage than at the anode. Thus in figure 12*B*, left, not even the voltage drop across 2 commutator bars, perhaps some 30 to 40 volts, was sufficient to transfer the cathode. In figure 12*C* and *D* the sudden breaks in the arc voltage give a measure of the voltage required to strike the new cathodes; these range from 30 to 175 volts, while even higher voltages in some cases caused no transfers.

**R. E. Hellmund:** The discussion contributed by Jones indicates how the data presented in the paper can be used to advantage to clarify certain practical questions.

Mason's reference to figures 5 and 6 of the paper is quite correct. These curves should start somewhat above the zero line if they are to represent arc voltages; they were extended to the zero line merely to indicate the starting current on which the curves were drawn. His other remarks are exceedingly interesting and give some very valuable explanations of the arc phenomena.

Penney's discussion indicates that with a roughness of 0.0003 the brushes may leave

the commutator a distance of one or two inches. Everybody familiar with railway practice knows that a figure much greater than the one given by Penney has often been allowed for the roughness of commutators, especially in some of the older motors. It therefore seems that a great deal of the commutator flashing in practice can be explained by commutator roughness, which supports the feeling I have had for some time that other causes, such as shocks caused by rail joints or mechanical vibrations of the motor as a whole, are of minor importance. The conclusion to be drawn from this is that commutator maintenance is possibly of even greater importance in reducing flashing in railway motors than any changes in the design of the motors. A review of the data given in the paper plainly indicates that flashing may occur with any motor design no matter what the field form of the motor may be. In railway work, space limitations make it practically impossible in the smaller motors to make the total distance between brushes more than

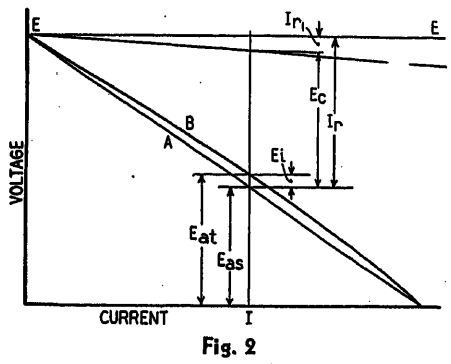

Fig. 2

5 or 6 inches, and since the total counter-voltage of the motor has to be induced within the distance between the brushes, the arc is likely to be drawn into the high-voltage region if the brush is off the commutator long enough.

Since it was not done in my paper, it may be well to call attention here to the fact that the transient arc characteristics as determined in the paper are not entirely independent of the circuit constants of the test arrangement. This may be illustrated by reference to the figure in this discussion. If a total voltage $E$ is impressed on the circuit, the ohmic drop in the circuit can be represented by the distance $Ir$ between the horizontal line $EE$ and the curve $A$. Curve $A$ must obviously be a straight line because the ohmic drop is proportional to the current. This simply means that with stable arc conditions the arc voltage $E_{as}$ is represented by the difference between the impressed voltage and the ohmic drop. If we consider, however, transient current conditions with a decreasing current, and if there is any self inductance in the circuit at all, a self-inductive voltage $E_i$ is induced, leading to a voltage $E_{at}$ for the arc voltage. This is the condition found in figures 5 and 6 of the paper. It is therefore evident that under transient conditions, the value $E_i$ will depend to some extent upon the inductance in the circuit. In a series motor, which is of the greatest practical importance in this study, conditions are different but the final results are somewhat similar. Instead of the large ohmic drop $Ir$, there is a small drop $Ir_1$, and in addition there is a counter electromotive force $E_c$ which is proportional to the current, at least as long as the motor is not saturated. The net result is that the sum of $Ir_1$ and $E_c$ is about equal to $Ir$, and the effect of any self induction is again represented by the value $E_i$. Under transient conditions the counter voltage may be influenced temporarily to some extent by the damping effects of the eddy currents in a solid frame portion upon the flux. Nevertheless, it is believed that the experimental data given in the paper are quite applicable to series motors, although it may be inadvisable to assume without further investigation that the same curves can be applied indiscriminately to entirely different conditions.

## Contact Drop and Wear of Sliding Contact

**Discussion and authors' closure of a paper by R. M. Baker and G. W. Hewitt published in the January 1937 issue, pages 123-8, and presented for oral discussion at the electrical machinery session of the winter convention, New York, N. Y., January 28, 1937.**

**R. E. Hellmund:** See discussion, page 602.

**V. P. Hessler** (Iowa State College, Ames): The results presented in this paper are very interesting and worthwhile as a step toward the ultimate goal of a complete understanding of sliding contact phenomena. The importance of the oxide film in contact drop phenomena seems to be definitely established by these and the former investigations of one of the authors. However, a large amount of experimental work will have to be done before the relative importance of the various factors involved in contact drop will be determined. For example, the oxide film alone does not explain the difference in contact drop obtained with the various grades of brushes. The difference might be attributed to abrasion but this seems hardly likely in view of the following simple experiment performed by the writer.

A pair of electrographitic brushes had been operated on a copper ring for several days with a current of 50 amperes per square inch. Then the ring was cleaned with fine carborundum paper and contact drops obtained simultaneously with the following results shown in table I of this discussion.

While the above indicates that abrasion does have an effect upon contact drop, the results were not nearly as pronounced as were expected. The abrasive paper must have cut through the oxide film, and the re-established film must necessarily have been of molecular dimensions considering the time required for an eighth of a revolution at 1,600 revolutions per minute.

Table I

| I | $E_+$ | $E_{av}$ | $E_-$ | |
|---|---|---|---|---|
| 50 | 0.68 | 1.57 | 0.85 | Before sanding. |
| 50 | 0.68 | 1.45 | 0.77 | After sanding lightly. |
| 50 | 0.67 | 1.40 | 0.73 | While sanding with 360 grit. |
| 50 | 0.69 | 1.48 | 0.80 | Running 2 minutes since sanding. |
| 50 | ..... | 1.20 | ..... | While sanding with 280 grit. |
| 50 | 0.66 | 1.42 | 0.76 | Running a few minutes since sanding. |
| 50 | 0.52 | 1.10 | 0.58 | While sanding with 280 grit. |

The authors suggest the possibility of a quasi-electrolytic action as a factor in ring wear, but show that the amount of material transferred is negligible compared to that in ordinary electrolytic action. In the case of brushes, the rate of wear is often not even proportional to the amount of current flow. With brushes not tracking the cathode metallic brush and the anode graphite brush always showed rates of wear independent of current density in the tests made by the writer. Of course, this does not apply to excessive values of current density.

The authors also suggest that, since there is less ring wear at the cathode section of the ring than at the zero-current point, material may have been picked up from some other part of the ring and deposited on the cathode section. It seems more logical to the writer to consider that the abrasion has been less at the cathode section than at the zero-current section. Very often a commutator will become threaded and the brushes dust under light loads, whereas these difficulties will all disappear under full load conditions. The same phenomena may be occurring in this synchronously operated ring.

The effect of operating sliding contacts in inert gases is indeed interesting. It will be another important step in advance when it is learned just why the presence of oxygen produces such a large increase in brush wear. The writer sincerely hopes that the authors will consider it worth while to repeat some of their experiments with a trailing brush to determine the importance of abrasion in this phenomena. It would also be interesting to analyse the gas in the tank for CO and $CO_2$ after a period of operation.

**R. M. Baker:** Hessler cites experiments in which he sanded slip rings while the brushes carried normal current, and found that the sanding operation resulted in only a small reduction in contact drop (contact resistance). It was inferred from this experiment that the oxide film is not an important factor in determining contact resistance. It must be pointed out, however, that quite different results would have been obtained if the experiment had been performed with a few milliamperes instead of normal current flowing in the contact. With normal current flowing through the contact, the film was already broken down to such an extent that sanding the ring had little effect. Sanding the ring with very low current flowing in the contact will some times result in a 1,000-to-one change in contact resistance.

It was unfortunate that the authors used the word "electrolytic" in describing the material transfer indicated in figure 5, for this word indicates the existance of an electrolyte. It was thought more likely that the material was transported by gaseous metal ions produced in the contact by vaporization, or some other process. The unequal wear might occur as Hessler and several others have suggested simply by nature of the fact that the abrasive effect of the brush

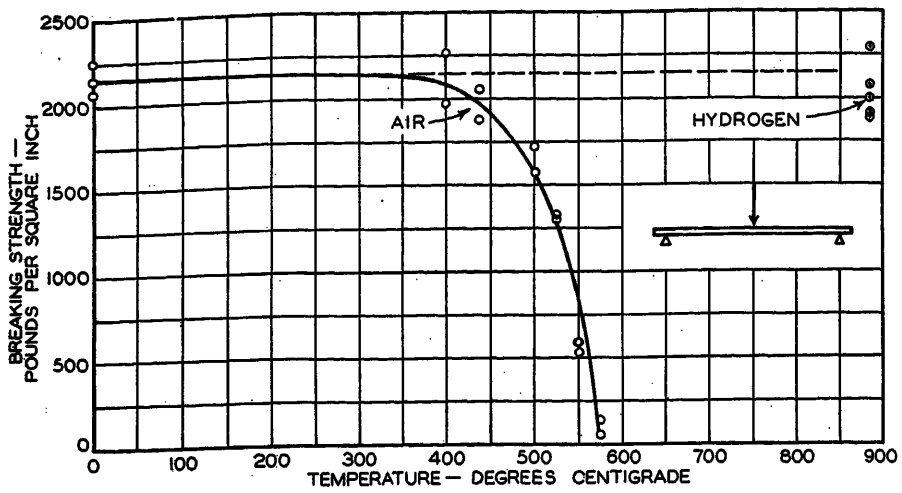

**Fig. 1. Effect of oxidation on the strength of carbon material**

is different over different parts of the rings, depending upon the amount and direction of the current flowing. There are 2 facts, however, which indicate very strongly that there is actually a transfer of material from the ring to the brush and vice versa. First, the polarity at which rapid ring wear occurs is correct for material transfer by positively charged metal ions; secondly, the variation in the wear curves is very nearly proportional to the current. If the results are to be explained on the basis of abrasion, it is necessary that the abrasion be not only dependent upon the direction but also upon the magnitude of the current.

Hessler mentions the fact that the brush wear data which he has obtained for metal graphite brushes cannot be explained by the picture of material transfer given above. This is to be expected, because brush wear is hundreds of times more rapid than ring wear and the small component produced by material transfer in the contact would never be noticed. This also raises another possible point of question which should be straightened out. Since the brush wears so rapidly, it is unlikely that much of the copper picked up off the ring would ever be redeposited. Thus, if copper is deposited on some part of the ring surface it probably is copper originally included in the body of the brush.

Some experiments with trailing brushes in an oxygen-free gas will be made as suggested by Hessler. It is doubtful, however, if such tests will give any evidence as to the process whereby brush wear is reduced upon going from air operation to operation in some oxygen-free atmosphere.

The authors have talked often about making an experiment to determine the amount of carbon monoxide and carbon dioxide given off by brushes during operation in air or in oxygen but have never found time to make the experiment. Such an experiment would furnish interesting information.

Hellmund has rightly brought out the fact that investigators of carbon brush problems have neglected to consider the effect of the carbon or graphite particles which are continuously being set free in the contact through the process of brush wear. If one assumes that all the brush wear results from particles 0.0001 inch in diameter being torn out of the brush face, one calculates that, for normal brush wear, about 50 to 100 particles are liberated from each square inch of brush area for each foot of travel. This gives some idea of the number of particles released in the contact during normal operation in air. It is surprising when one realizes that on the above assumption a brush one square inch in area, operating on a ring with a speed of 5,000 ft. per minute, would give off half a million particles in one minute.

It is not known just how these particles leave the contact or what part they play during the time they are in the contact. Hellmund makes a number of interesting suggestions, and following these, an investigation will be undertaken by the authors to determine experimentally the size and number of the particles given off by different brushes.

Hellmund suggests that the roughness of the voltage records (figure 2 of paper) for the negative polarity might be explained by the movement or disappearance of loose carbon particles in the contact. It will be seen, however, by a comparison of alternate periods of the voltage wave (figure 2 of paper) that the variations are a function of the ring position and must therefore be due to some condition existing on the ring surface rather than in the brush face. This same effect is even more noticeable during d-c operation where the voltage drop record repeats almost exactly over successive revolutions when 3 or 4 revolutions are observed on one oscillogram.

Hellmund mentions an earlier article in which the authors suggested that oxidation of the brush material immediately adjacent to the contact resulted possibly in a weakening of the brush structure and the high rate of brush wear commonly observed in air. Further evidence along this line is given by the curves of figure 1 of this discussion.

To test the weakening effect produced in a brush material by exposing it to various temperatures in air, the following experiment was made. Samples of an electrographitic lamp-black, $\frac{1}{2}$ inch wide by 3 inches long by $\frac{1}{16}$ inch thick, were subjected to various temperatures for 20 hours in an electric furnace. These samples were later subjected to a breaking test with the results indicated in figure 1. The strength recorded is the modulus of rupture in pounds per square inch.

It will be seen that in air the material began to loose its strength around 350 degrees centigrade and had zero strength around 570 degrees centigrade. Even the samples which had zero strength, still retained essentially their original size and shape and it seemed as if the weakening had occurred by a surface oxidation of the individual particles of the brush to weaken the bonds until the sample was just ready to fall apart. In hydrogen, similar samples were heated up to 880 degrees centigrade with practically no weakening. This is in line with previous arguments and is a little more evidence that oxidation of the brush material adjacent to the contact is an important factor determining the rate of brush wear in air.

In closing it should be mentioned that R. Holm of the Siemens Company in Berlin made experiments some years ago which demonstrated some of the results given by figure 2 in the paper. A copper ring was operated with a low value of direct current until the contact resistance was high. The ring was then stopped and part of the surface was subjected to a heavy current. Afterward the ring was allowed to run with only a small current flowing while the contact drop was observed with the oscillograph. The variation of contact drop around the ring showed that the section of the ring surface which had been subjected to the heavy current continued for some time to offer a much lower resistance to the flow of current than did other sections of the ring surface. The results of this experiment were never published but were communicated verbally to one of the authors during his visit to Berlin in 1932.

## Self-Regulated Compounded Rectifiers

**Discussion and authors' closure of a paper by W. Melvin Goodhue and R. Burton Power published in the November 1936 issue, pages 1200–5, and presented for oral discussion at the electrical machinery session of the winter convention, New York, N. Y., January 28, 1937.**

**F. N. Tompkins** (Brown University, Providence, R. I.): The authors are to be congratulated for producing such a timely and interesting paper.

Since little mention was made of a single-phase full-wave rectifier working in the manner described in the paper, it was thought worth while to set one up in the laboratory. It was found to give results comparable with those given in the paper. For instance, with a straight rectifier, i.e., not self-regulated nor compounded, when the input voltage was varied from 150 to 250 volts the output voltage varied from 102 to 178 volts. With the input voltage held constant at 230 volts and the load varied from zero to full load, the output voltage varied from 184 to 159. With the rectifier self-regulated but not compounded, a variation of input voltage from 150 to 250 gave a change of output voltage from 97 to 119 volts. When the input voltage was held constant at 230 volts a variation of load from zero to full load gave an output voltage change from 119 to 115 volts. It is quite possible that with changes in the apparatus

used even better results would have been obtained. These tests, besides indicating that the circuit may well be used with single-phase input, pointed out several facts which either were not stressed or were not mentioned by the authors.

The current transformer used in the 3-phase arrangement seems to be of special design, being for 3-phase operation. Three common single-phase current transformers should not be used since they would be working into a half-wave rectifier and would have no secondary load every alternate half cycle. This would lead to saturation of the cores and a high voltage drop across the primaries. In the single-phase compounded rectifier, as set up in the laboratory, it is necessary to use a current transformer with a center tap in order that the current compounding may be supplied from a full-wave rectifier. It was also found to be advisable to filter the output of this rectifier for best results, a choke and condenser being used for this purpose.

The ratio of the main transformer must be carefully chosen when designing a rectifier of this kind. To secure either voltage compensation or compounding, it is necessary to operate the rectifier at some lower voltage than would normally be given by the chosen transformer ratio. This is necessary in order that the regulating voltages from the drop wire across the output and from the current-transformer rectifier may have control of the grids of the tubes. The amount of voltage below normal at which the rectifier unit must operate depends upon the amount of voltage regulation desired.

In the paper small lamps are shown in the grid circuits acting as protective resistors. In the single-phase arrangement it was found advisable to use much higher values of resistance than is represented by these lamps, 5,000 ohms being a good value. The grids should not take any more current than is necessary.

**L. A. Kilgore** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): The authors describe a method of automatically controlling the voltage of grid-controlled rectifiers, which utilizes the output voltage of the rectifier to control the grids. The authors show a smoothing inductance which takes out part of the pulsation of output voltage. If the smoothing action is not complete, the grid picks up when the output voltage is at the minimum point. Hence, it attempts to regulate for a constant minimum voltage. The difference between the average and minimum voltage will be the function of the load current, load-circuit inductance, and resistance. The authors describe a means of compounding which takes care of the change due to load current. The writer would like to ask whether or not they would expect changes in average voltage if the character of the load circuit changed, especially if the load inductance changed.

If the ripple in the output voltage was completely filtered out, then any slight variations in the critical voltage of the grids would cause wide variations in the firing of individual anodes and cause serious unbalance of load. It would seem that to keep the same accuracy of firing, the ripple voltage must be of the same order of magnitude as the sine wave grid voltages which have been previously used for controlling the firing of grids. If this is true, nothing is gained over the conventional method of impressing grid voltages from a grid transformer, and it has the disadvantage of being dependent on such factors as the inductance of the load circuit. The writer would appreciate the authors' comments on these points for it may be that some of the functions of the apparatus described have been misunderstood.

When considering the control of rectifier voltage by grids, whether automatic or manual, it should be observed that any reduction of voltage is accompanied by a nearly proportional reduction in power factor, and an increase in harmonics. This fact somewhat limits the general application of such control, but the writer feels that there will be numerous applications where the automatic control of rectifier voltage will be used. Several automatically regulated rectifiers have been built, one using a conventional current regulator, such as might be used on a rotating machine. Another rectifier using voltage and current compensation was found to give very flexible control of the regulation characteristics.

**Didier Journeaux** (Allis-Chalmers Manufacturing Company, Milwaukee, Wis.): The authors are to be given credit for presenting a method of rectifier control of sufficient interest to make their readers desirous of obtaining additional information on the details of the process of operation of their system. In particular, curves would be desirable showing the different characteristics obtained by varying the voltage of the bias battery and the tap of the potentiometer, and by maintaining the tubes in an oil bath at different constant temperatures. Oscillograms of the input and output voltages, of the d-c load current and of the grid voltage during steady state operation and during transients would also be of assistance in obtaining an insight into the action of the grids. The omission of a d-c load-smoothing inductance in figure 7*b* appears to be inadvertent.

While the results reported by the authors are quite interesting, it is necessary to bear in mind the limitation to which the system is subject. In particular, the action of the grid control relies on the curvature of the grid characteristic and is of extreme sensitivity. This renders the system easily disturbed by any irregularity in the action of the tubes to the extent that, in some of the circuits, tubes must be selected and perhaps also matched to give reliable results. If the grid characteristic is subject to variations, the output voltage or current will receive the same variations amplified in a constant ratio. This would probably render the regulator entirely inapplicable to the control of rectifiers of the mercury-pool type, for which mechanical regulators of the rocking sector type have been found entirely satisfactory. Such regulators have been used with great success in this country and abroad for controlling constant voltage, compounded, and constant current rectifiers, the latter being utilized in some large electrolytic plants. While rocking sector regulators have not been used on currents requiring regulation through a load range including short circuits, they are perfectly adapted for that purpose. By the addition to the regulator of a high-speed relay, regulation could be maintained through suddenly applied short circuits within such limits and at such speeds as to meet the requirements of most practical applications.

**C. L. Dawes** (Harvard University, Cambridge, Mass.): During the past few years it has become increasingly evident that ionic devices were certain to replace relays, certain types of rotating machinery and many types of regulating devices. For example, in new substation installations, the mercury-arc rectifier has virtually superseded rotating machinery in the conversion of alternating to direct current. Because of the absence of rotating elements, windings and iron cores, such rectifiers are inherently more efficient, especially so at light load, and are much lighter than equivalent rotating machines. Moreover, because the ions constituting the rectifying medium have insignificant inertia, and respond with extreme rapidity to both electric and magnetic fields, it is possible to obtain characteristics, and to control current and voltage in a manner which is impossible with rotating machinery. This paper by Goodhue and Power is an excellent illustration of some of the results which can be obtained with such ionic devices.

I am first calling attention to the method of grid control which they employ as is illustrated by figures 1*a*, 1*b*, and 7*a* and 7*b*. The usual method of grid control is to apply an alternating electromotive force to the grid and to control the instant of firing either by shifting the phase of this electromotive force, or by changing its magnitude. The authors obtain greater sensitivity, less effects from temperature, and more positive action by connecting all the grids together and applying a direct-current voltage to them. This electromotive force is supplied jointly by a constant source of electromotive force, such as a battery, and a potentiometer connected to the d-c system supplied by the rectifier. As the authors state, the regulator operates so rapidly that the pointer of a d-c voltmeter shows no noticeable flicker with large and sudden changes in input voltage.

By the addition of current compounding a wide range of voltage-current characteristics may be obtained, from almost any desired degree of cumulative compounding to almost any degree of differential compounding as shown by figure 3. Also constant-current characteristics and characteristics combining constant-current to the limit of the rectifier operation and then through nearly constant potential to zero current all may be obtained merely by suitable adjustments of the shunt and series regulating resistances as shown by figure 4.

Hence it appears that these methods offer possibilities in industrial motor control, not readily obtainable with the usual d-c sources. As pointed out by the authors, by the use of the characteristics of figure 4 motors may be started with any desired value of constant torque and brought smoothly up to rated speed. All starting equipment is eliminated together with the pulsations in starting current caused by the intermittent closing of contactors. The method makes possible by simple means the precise control of many processes which control heretofore was only possible by

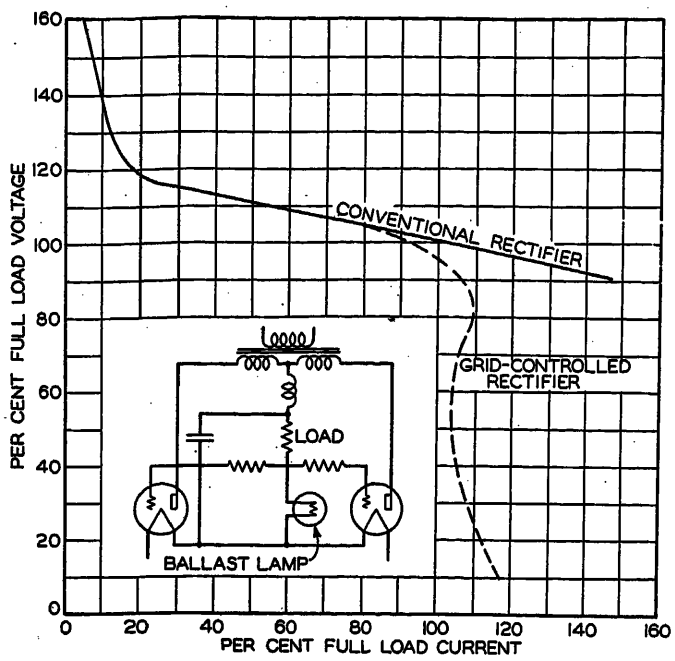

Fig. 1

means of complicated and cumbersome electromagnetic control equipment. As an example, if it were desired to maintain the speed of a motor constant it could be separately excited and a direct-current magneto connected to the shaft. The terminals of the magneto would be substituted for the potentiometer $S$, figures 1*a*, 1*b*. Any change in speed of the motor would change the electromotive force applied to the grids, and the electromotive force at the motor terminals would change correspondingly. If compensation for the small effects of temperature on the critical grid voltage were desired, a slight degree of current compounding could be introduced, using the connections of figure 1*b*. There are many other applications of such automatic control such as maintaining the correct distances in alignment processes, controlling temperature and pressure, etc.

Heretofore constant direct current has been obtained by means of the constant-current transformer supplying constant single-phase current to single-phase rectifiers. As shown by figure 4 the methods developed by the authors make it possible to obtain such constant direct current from a polyphase rectifier, with advantages over the constant-current transformer method. The moving coil with the accompanying mechanism is eliminated. The constant-current transformer cannot maintain constant current during sudden changes of load. With the moving coil in any fixed position the current locus is a circle. Hence the coil must move to maintain constant current, and, owing to the inertia of the mechanical system, considerable time is required for readjustment of the position of the coil. With the system shown by the authors, response to load changes is practically instantaneous. Moreover, their system constitutes a balanced 3-phase load whereas the single-phase, constant-current transformer produces unbalancing in 3-phase, systems which under some conditions may be objectionable.

To my mind this paper is valuable, not only in showing the definite characteristics that are obtainable with a controlled mercury-arc rectifier, but it also shows the flexibility that is obtainable by means of ionic control devices and it opens up wide possibilities in the field of industrial power applications.

**Reuben Reiter** (Harvard University, Cambridge, Mass.): The data presented in the curves of this paper show that the maximum power controlled by the authors in their experiments was of the order of 2 kw. It is desirable to know the economics of this method of control when applied to much larger blocks of power. The dollars and cents saved by this method over other existing methods will determine its present value.

Would it not be possible to economize on the initial cost of the control installation by employing a single phase for control rather than 3 phases. The system shown by the authors employs 3-phase transformers and requires 3 rectifying units to supply the d-c control voltage. The method is a balanced one, but is it necessary for the ordinary installation.

**G. H. Rockwood** (Bell Telephone Laboratories, Inc., New York, N. Y.): The compounding circuits suggested by the authors are of considerable interest since they permit of cumulative compounding so conveniently. As the authors suggest differential compounding makes possible the construction of a rectifier which may be used for d-c motor control, or one the output of which may be short-circuited without damage to tubes or associated equipment. Because of the convenience of differential compounded circuits it seems pertinent to call attention to another type of circuit which makes possible differential compounding in a cheap and simple manner. The circuit for a single-phase rectifier is shown. In this circuit the load current is passed through a series resistance, the drop across which supplies the grid excitation for the rectifier tubes. If this series resistance is a nonlinear device such as a tungsten-filament ballast lamp, the voltage drop across it even at full-load current may be made small enough so that the grids have very little negative bias, but for overload currents the grid bias rises rapidly. Because of the curvature of the grid characteristics of negative grid tubes, a small grid bias causes practically no change in output of the rectifier. Consequently, the load-regulation characteristics for the conventional rectifier and the differentially compounded grid-control rectifier are substantially identical except in the overload region. It will be observed from the figure that the rectifier may be short-circuited without having the load current rise to excessive values. It should be added that the rectifier operation is stable even under short circuit conditions.

**Myron Zucker** (Detroit Edison Company, Detroit, Mich.): The authors are to be commended for trying to apply the inherent speed of electronic equipment to work-a-day jobs. Such development, especially toward simplification, is needed if industry is to profit by electronics. Despite the quick action theoretically obtainable with electronic regulators and controllers almost all regulating work can still be done more economically by other means. Even in such a wide-open field as the high-speed regulation of distribution circuits to eliminate lamp flicker, no satisfactory regulator has yet been developed: it is still necessary to resort to the "brute force" method of making every element in the circuit oversize. As long as transformer capacity and copper come cheaper than tubes, there can be no quarrel with the present method of handling the situation. Perhaps a continual assault on the regulation problem will some day produce more refined solutions.

However, despite the desirability of the study, the authors' solution seems to be limited to certain special applications. Several factors seem to make it unsuitable for commercial work.

The first control scheme described in the paper is the most attractive because of its simplicity. It depends on balancing the output voltage of the rectifier against a battery, to energize the grids. This has 2 disadvantages:

1. An ordinary battery is not as reliable a long-time voltage standard as is commonly considered, so that—especially with the sensitive differential principle used in the grid circuit—erratic operation is likely to occur. How much current—instantaneous and average—and in which direction—was drawn through the battery?

2. Ripple is demanded in the output voltage. Although too much is undesirable, it is obvious that too little would be even worse. In the extreme case of no ripple, the average voltage would be obtained from a series of "full on" operations followed by all tubes being entirely "off" for several cycles.

It would help if the authors would tell how much ripple they have found desirable in their tests, and also whether they have run any tests for extended periods of continuous operation. Also, what magnitudes of battery voltage was used? How do the values depend on load, voltage, and the range covered by these? What are the quantitative conditions for figure 2, the curve showing perfect regulation? Can this curve be reproduced at will for various

loads and voltages? Once the proper adjustment has been made for a certain voltage-load characteristic with a given supply voltage, will a similar curve be obtained for a different value of supply voltage?

It seems that the ripple might be reduced by placing filters on the load side of the control potentiometer *S*. Have the authors tried this? Since a certain minimum of

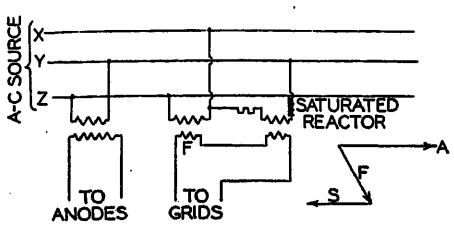

Fig. 2

ripple is required for control, is it not true that the ripple is worse with this type of control than with other types unless such filter can be used?

Use of tubes that "fire" with negative grid voltages is suggested by the authors. This might better some of the curves and permit use of weaker grid circuits (or ease the battery service), but would increase the chances of erratic operation. These "negative grid" tubes have a tendency toward random firing even with the best of grid excitation; it might be too much to expect them to give good service on the slim margin provided by voltage balancing.

It might be suggested that similar curves including compounding have been obtained in a more reliable way by a-c excitation. For instance the circuit shown in the diagram will give very close regulation. "Compounding" can be added with phase adjustable, giving a wide range of characteristics available. Such a control circuit has been applied to rectifiers and to excitation of an alternator. In the latter case, an added feature is that overspeed may be made to remove excitation and trip the main alternator circuit breaker. This type of circuit does what the authors set out to do—control without auxiliary tubes—and at the same time provides a definite, predictable voltage to the main grids.

**W. M. Goodhue:** Tompkins reports verifying the circuits given in the paper with a single-phase circuit in his laboratory. The authors appreciate the interest which he shows, particularly in view of the difficulties encountered in a different laboratory not having equipment specially designed for this new circuit. For example, the amount of smoothing inductance must be co-ordinated with the rectifier circuit in order to obtain a specified uncompensated characteristic.

The current transformer is stated in the paper to be polyphase. It would naturally follow that, with a single-phase set, transformers with the center tap would be employed. In filtering the pilot rectifier, it should be remembered that too much grid filtering will introduce time lag, and Tompkins perhaps uses grid filtering to compensate a long commutation period in the main rectifier.

In all grid-controlled rectifiers and inverters it is usual and essential to employ a main transformer turn ratio giving a maximum d-c voltage greater than the operating voltage. Even in a d-c dynamo, the shunt-field coils are designed for 80 per cent or so of full voltage, the remainder being absorbed in the field rheostat.

The value of grid resistance to be used depends on the choice of tubes, and must be co-ordinated with potentiometer resistances. Tompkins may have used a different type of tube than the authors. Also, the value of resistance is not critical.

L. A. Kilgore asks whether the authors would expect any change in average voltage if the load *inductance* is changed. This condition is peculiar in that *load* inductance, unlike the smoothing inductance, is outside of potentiometer *S*. This tends to *increase* the *voltage* ripple across potentiometer *S*, and hence the average voltage. This effect may perhaps be overcome by the insertion of condenser-resistance filtering in the contact *S* lead, in place of smoothing inductance in the power circuit.

The question of the accuracy of firing does require expounding. Inspection of curves, such as figure 2, shows *extraordinary accuracy* all out of proportion to any results obtainable with *static* grid circuits having similar magnitudes. Protective devices were employed in these experiments and would have shut down the equipment if serious anode unbalance ever occurred. No shutdown due to unbalance occurred, showing that this effect was not serious. The peak current equals the load current, so that only firing-time unbalance need be considered. Kilgore neglects the fact that unbalanced firing would produce an *unbalanced ripple*. The resulting regulator action would automatically restore balance immediately. In other words, failure of a tube to fire at the appointed time causes the ripple to continue dipping *beyond* the appointed time with accelerating downward slope, forcing the tube to fire close to the appointed time.

Therefore, ripple voltage in this circuit may be much smaller than the sine-wave voltages usually employed in grid circuits. Of course, if *complete filtering* is desired, it can be added in the d-c load itself *beyond the potentiometer S*, without depriving the grid circuit of ripple.

With large ripple, compounding would still work, and high voltage sets (250 volts up) would have a small *per cent* ripple and hence regulate. The authors agree with Kilgore that the advantages of grid control far outweigh the reduction in power factor.

Didier Journeaux suggests oscillograms for the purpose of understanding the grid action. Different states of operation are possible, all satisfying the equations of the paper and giving the regulator action. The extraordinary accuracy (figure 2) compared with the small ripple voltage operating the grids would require special experiments to understand. Artificial variation of critical voltage of one tube must be introduced.

Therefore, the number of oscillograms and amount of research would be so large as to properly belong in a second paper on the subject.

The omission of smoothing inductance in figure 7*b* was probably due to the custom of combining interphase transformer and smoothing inductance by the use of a high-leakage interphase transformer.

The characteristics varying the potentiometer taps and bias battery are shown in figures 3, 4, and 6. Only slight improvement with oil bath may be expected, since other factors such as per cent ripple still vary with current.

The question of tube irregularity and grid variations has been considered in answer to Kilgore's discussion. The grid control does not rely on the curvature of the grid characteristic. The authors wish to thank Journeaux for calling attention to the fact that mechanical regulators can possibly be designed for high speed, where the grid current to be controlled is small. However, such regulators are limited economically to large size rectifiers.

G. H. Rockwood has a very interesting differential-compounded rectifier. It seems to depend directly on the grid critical voltage and hence be subject to wide variations with temperature and supply voltage. In the dotted curve portion, the current varies considerably, while the authors' characteristics are linear (figure 4) with nearly constant current. This is because the use of a bias battery in the authors' circuit reduces the per cent of variation due to critical grid voltage. For example, assume a critical grid voltage of 5, which varies say one volt, and a battery of 90 volts. For Rockwood's circuit, 1 volt in 5 is 20 per cent variation; for the authors' circuit, 1 volt in 90 is 1.1 per cent variation. With a 180-volt battery, the variation is only 1 volt in 180 or 0.55 per cent. Thus, the use of a bias battery or its equivalent is essential in any d-c controlled rectifier circuit to eliminate grid variations. The use of a tungsten-ballast filament introduces time lag, especially for currents of 5 or more amperes; this lag is minimized by operating smaller filaments in parallel. The power loss in the ballast probably equals the tube loss, limiting application to small equipment, where first cost rather than efficiency is important. Of course, voltage regulation and cumulative compounding are not obtainable.

C. L. Dawes offers a very illuminating discussion of the industrial applications of the new circuit, and also the principles of operation. As he states, the moving-coil type of constant-current transformer is practically helpless during a rapid change, and reverts to an inferior circle-diagram characteristic. When the moving coil is near the stationary coil, the dynamic charateristic is especially inferior, the short-circuit current being several times the operating current, because the reactance is low. The authors feel with Dawes that the flexibility of grid control methods is enhanced by the new circuit.

Reuben Reiter evidently wishes the authors to discuss economics of this circuit. With large blocks of power the following relations exist:

1. Entire control-circuit kva and power loss is negligible. No phase shifters are necessary. Therefore, the expense of control equipment, both initial cost and operating cost, is very small compared to the main equipment.

2. Other methods of obtaining constant current from a constant-potential source are expensive, such, for example, as moving-coil transformers, monocyclic networks.

3. In addition, the dollars and cents problem involves other factors introduced in connection with the purpose of the equipment, the facilities available, and the financial nature of the application. Obviously, too general statements are misleading.

Reiter also suggests a single-phase control with polyphase power. To avoid throwing the power anodes out of balance, considerable filtering of the pilot rectifier may be necessary, with resulting time lag. Initial cost is usually vital in small installations. For these, the *entire power equipment* may be single-phase, the pilot rectifier may consist of a *cheap full-wave radio tube* (type 83, 83*v*, or 80), and the current transformer of inexpensive power-pack construction.

## Dyadic Algebra Applied to 3-Phase Circuits

August 1936 issue, pages 876–82.

## Complex Vectors in 3-Phase Circuits

December 1936 issue, pages 1356–64

**Discussion of 2 papers by A. Pen-Tung Sah published in the August 1936 and December 1936 issues and presented for oral discussion at the tensor analysis session of the winter convention, New York, N. Y., January 26, 1937.**

Giuseppe Calabrese (The New York, N. Y. Edison Company, Inc.): When new methods of analysis are applied to any branch of science, the first step taken is that of explaining well-established facts with the new methods. In this respect, and in connection with Sah's papers, perhaps, it may be of some interest to derive the formula of the force between 2 elements of conductors carrying currents, in the light of the theory of dyadics, and to show how this force may be visualized as being proportional to the direct product of a vector by an antiself-conjugate dyadic.

With reference to the figure below, let $\dot{I}$ and $\dot{I}_1$ indicate the magnitudes and space directions of the currents flowing in the 2

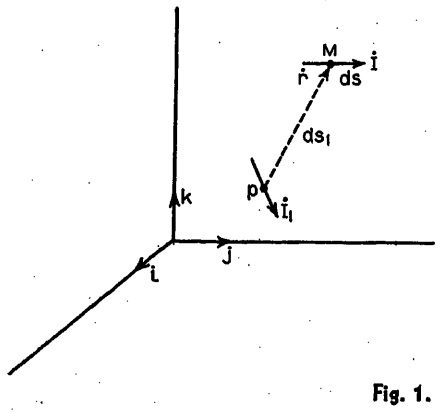

Fig. 1.

elements $ds$ and $ds_1$ of the 2 conductors located respectively in $M$ and $P$. Let $\dot{r}$ be the vector $PM$ positive from $P$ to $M$.

The force $\dot{F}_0$ exerted on the element $ds_1$ of the conductor carrying the current $\dot{I}_1$ by the element $ds$ of the conductor carrying the current $\dot{I}$ is given by (the dot on the letters $\dot{I}$, $\dot{I}_1$, $\dot{r}$, $\dot{F}_0$, is used to indicate vector quantities. The same letters without any additional sign indicate scalar quantities:

$$\dot{F}_0 = \frac{K\,ds ds_1}{r^3}\,\dot{I}_1 \times (\dot{r} \times \dot{I}) \qquad (1)$$

where $K$ is a constant depending upon the physical nature of the medium interposed between 2 elements.

From vector analysis, it is known that the vector $(\dot{r} \times \dot{I})$, when used in cross multiplication, is equal to the anti-self-conjugate dyadic $(\ddot{I}r - \dot{r}\ddot{I})$ in direct multiplication, used as a prefactor or post-factor, depending on whether $(\dot{r} \times \dot{I})$ is used as a prefactor or post-factor. The expression (1) of the force $\dot{F}_0$ may, therefore, be rewritten as follows:

$$\dot{F}_0 = \frac{K\,ds ds_1}{r^3}\,\dot{I}_1 \cdot (\ddot{I}r - \dot{r}\ddot{I}) \qquad (2)$$

That is, the electromagnetic force exerted on an element $ds_1$ of a conductor carrying the current $\dot{I}_1$, by the element $ds$ of a second conductor carrying the current $\dot{I}$, is proportional to the direct product of the current vector $\dot{I}_1$ into the anti-self-conjugate dyadic $(\ddot{I}r - \dot{r}\ddot{I})$. It will be recalled now, and it is apparent from equation 2 that the direct product of a vector by an anti-self-conjugate dyadic lies in the plane common to the antecedents and consequents of the dyadic. It will be recalled also (or it may be proved directly by expanding the dot product $\dot{F}_0 \cdot \dot{I}_1 = \frac{K ds ds_1 r}{r^3}\,\dot{I}_1 \cdot (\ddot{I}r - \dot{r}\ddot{I}) \cdot \dot{I}_1 = 0$) that the direct product of a vector by an anti-self-conjugate dyadic is perpendicular to the vector. Once these 2 rules are recalled, the space position of the force $\dot{F}_0$ is immediately visualized from equation 2. $\dot{F}_0$ lies in the plane of $\dot{r}$ and $\dot{I}$ and is perpendicular to $\dot{I}_1$. From (2), the 2 components of the force $\dot{F}_0$ along $\dot{r}$ and $\dot{I}$ may also be readily computed respectively at:

$$\frac{K ds ds_1}{r^3}\,(\dot{I}_1 \cdot \dot{I})\dot{r} \quad \text{and} \quad \frac{K ds ds_1}{r^3}\,(\dot{I}_1 \cdot \dot{r})\dot{I} \qquad (3)$$

Furthermore the 3 space vector $\dot{I}$, $\dot{I}_1$, $\dot{r}$ may be expressed in terms of any arbitrarily chosen orthogonal system $ijk$ as follows:

$$\dot{I} = xi + yj + zk$$
$$\dot{I}_1 = x_1 i + y_1 j + z_1 k$$
$$\dot{r} = r_1 i + r_2 j + r_3 k$$

Correspondingly the dyadic $(\ddot{I}r - r\ddot{I})$ in nonion form becomes:

$$(\ddot{I}r - r\ddot{I}) = (r_2 x - r_1 y)(ij - ji) + (r_3 x - r_1 z)(ik - ki) + (r_3 y - r_2 z)(jk - kj)$$

From which:

$$\dot{F}_0 = \frac{K ds ds_1}{\sqrt{r_1^2 + r_2^2 + r_3^2}} \times [\{y_1(r_1 y - r_2 x) + z_1(r_1 z - r_3 x)\}\, i + \{x_1(r_2 x - r_1 y) + z_1(r_2 z - r_3 y)\}\, j + \{x_1(r_3 x - r_1 z) + y_1(r_3 y - r_2 z)\}\, k] \qquad (4)$$

By means of either (3) or (4), the electromagnetic force between 2 elements of conductors carrying currents may be calculated. In the practical applications, if the expressions (3) are used, the vectors $\dot{I}$, $\dot{I}_1$, $\dot{r}$ may be decomposed in such a manner, or if using equations 4, the systems $ijk$ may be so chosen as to reduce the necessary calculations to a minimum.

The forces on finite lengths of conductors are calculated by means of appropriate integrations.

Of course the same conclusions may be reached, without much difficulty, from equation 1 by expanding the triple vector product according to the rules of vector analysis, without any knowledge of dyadics.

K. L. Wildes (Massachusetts Institute of Technology, Cambridge): The authors of this group of papers have shown remarkable genius in the application of 2 closely related branches of mathematics to electric-circuit problems. The method of Sah is limited to 3-phase, or 3-branch circuits, since it is based upon the 3-dimensional vector analysis of Gibbs. I am inclined to agree with Sah, however, that the better initial approach to the whole subject of "higher circuit analysis" is through the vector algebra rather than the tensor algebra.

During the term just closing at MIT I have been presenting, as a part of one of my graduate courses in electric power-circuit theory, this vector algebra method of solving 3-phase unbalanced circuits. From this experience it is my opinion that the best pedagogical approach to this whole matter is, first, to study thoroughly the elements of vector algebra and linear vector functions, as developed by Gibbs and Wilson. This would be followed by a study of Sah's first paper in which the application is made to instantaneous 3-phase voltages or currents as phase components of a 3-dimensional vector. This paper also develops the simpler operations with impedance and admittance dyadics. Then, just as we usually go from the study of instantaneous values of alternating quantities to the complex representation, we proceed to Sah's second paper, in which we find the vector method applied to currents and voltages in the complex form. This transition is not difficult because the differences between vectors whose components are instantaneous values and those whose values are complex are practically the same differences as those which exist between single-phase quantities.

The final, and perhaps the most difficult step in the application of this method to the solution of circuits, is the development of the technique of solving equations once they are written. This technique involves great ingenuity, as well as a great deal of experience in handling vector equations. Many of these applications and ingenious methods of solving vector equations have been worked out by Sah, and it is my hope that these will soon be made available in future papers, or preferably in the form of a book.

Since this method is a direct competitor of the method of symmetrical components in solving unbalanced 3-phase circuits, it may be in order to make a comparison of these 2 methods. It has been our experience that circuits involving balanced impedances, except at a single point, or

possibly 2 points of unbalance, are more easily solved by the method of symmetrical components, while circuits possessing impedances of considerable unbalance are probably solved with about the same ease by the new method as with symmetrical components. There is probably some degree of complexity at which the vector method of solution becomes easier than the component method. This is especially true if some systematic, or perhaps mechanical method, of aiding the solution to the equations can be developed. The technique of understanding and using the method of symmetrical components is certainly much simpler than the new method, and would be, I should say, a prerequisite to studying it. For example, in the paper dealing with complex vectors the zero-sequence, positive-sequence, and negative-sequence components of a vector representing a set of voltages are found by dotting this vector with the isoclinic or zero-sequence vector $u$, the positive-sequence vector $f$ and the negative-sequence vector $b$, respectively. In our class work we have duplicated the symmetrical-component solutions of circuits with impedances unbalanced at one point in terms of the new vector *notation* simply to become acquainted with this notation. We have then proceeded to solve the same problems by not only a notation, but a *process*, which characterizes Sah's work.

A careful study of this vector method not only has merits of its own, but forms an excellent foundation for the understanding of tensor algebra which is the subject of the papers by Kron, Boyajian, and Bewley.

In conclusion, I cannot refrain from saying that I have great admiration for the fundamental development of these methods of analysis by Sah and Kron. The time for evaluating their contribution has not yet arrived, but it is the responsibility of the electrical engineers and the professors of electrical engineering in the colleges to give attention to these methods and to come to a sound evaluation of their utility within the next 2 or 3 years. Not until many problems have been worked out to final numerical results can we say definitely whether the new methods are capable of organizing and clarifying large classes of problems, or whether, in general, the use of these methods makes the problems more obscure and more difficult of solution. I am personally enough interested to attempt to find the answer to this question.

**Joseph Slepian** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): The 2 papers by Sah are to be commended for the interesting material they present, and the temperate tone used by the author in estimating the value of his results. In all cases, the arbitrary character of certain assumptions are plainly stated. The definition of a scalar as having magnitude but no direction, and a vector as having magnitude and direction is in agreement with all previous usage. If any fault is to be found, it is that the mathematical terminology is a form which seems to be passing out of use. The dyadics of Gibbs are perhaps in the same class as the quaternions of Hamilton, namely, seldom used in modern mathematical works. It is an interesting evidence of the rapidity of progress in mathematics that the reference book, used by Sah, reference 1 in his first paper, is only 12 years old.

The first section describing "Three Phase Impedance as an Entity" makes it quite clear, by leaving out all irrelevant notions, that the impedance may be regarded as an entity, with 9 components in the 3-phase case, without requiring it to be a tensor, dyadic, or anything other than a set of numbers describing an electrical system.

The next section introduces the dyadic notation with the pairs of unit vectors occurring as symbols. Strangely enough, these double unit vector symbols occur nowhere else in the paper. I think this is the best evidence of their unnecessary and irrelevant quality.

As Sah states, the geometrical representation which he gives to a 3-phase set of currents or voltages, namely, an ellipse with center at a fixed origin, and a specified initial point on the ellipse, is in a certain sense arbitrary. But so too is the geometrical representation of a single aternating quantity as a vector in a plane. But in this latter case, all the arithmetic calculations we make with single-phase quantities correspond to simple geometric operations upon their corresponding vectors. Thus the addition of 2 single-phase quantities corresponds directly to the vector addition of their corresponding vectors. It is these correspondences which make the vector representation of single-phase quantities so valuable.

But unfortunately, not quite so good a case can be made out for Sah's ellipse representation of 3-phase quantities. The ellipse corresponding to the sum of 2 sets of 3-phase quantities is not related in any so obvious or suggestive a manner to the ellipses corresponding to the individual sets of 3-phase quantities. However, certain calculations, made with 3-phase quantities do have simple, geometrical equivalents in Sah's representation. The 3 symmetrical components are represented by 2 circles and a line which have very simple relationships to the ellipse as Sah shows. Similarly, changing from delta to wye components or vice versa, corresponds to simple operations upon the representative ellipse.

In his second paper, Sah generalizes from the notion of a vector with real components to that of a vector with complex components, and shows well the value of these ideas in application to 3-phase alternating quantities. The mathematics is all good and valid. It seems to me, however, that it might be put into more attractive form by generalizing from the real space to the "unitary" space with complex components, now used so extensively in quantum mechanics.

In vector analysis in real Euclidean space, a fundamental scalar is the product of two vectors defined as

$$X \cdot Y = x_1y_1 + x_2y_2 + x_3y_3$$

with obvious significance to the notation. This expression must be generalized to meet the case where $x_1$, $x_2$, $x_3$, $y_1$, $y_2$, $y_3$, may be complex numbers instead of only real numbers. Now it is not necessary in making the generalization, to use precisely the same formula as for the case of reals, but it is sufficient, to use a formula for the case of complex components which will reduce to the above formula when the components become real. Thus we may define for the scalar product, instead of the above expression, which Sah uses, the following:

$$X \cdot Y = x_1^*y_1 + x_2^*y_2 + x_3^*y_3$$

where $x_1^*$, $x_2^*$, $x_3^*$ are the conjugates of $x_1$, $x_2$, $x_3$. Obviously when $x_1$, $x_2$, $x_3$ are real this expression reduces to the preceding one.

The definition of the scalar product in this way, by a Hermitian instead of a quadratic form, has many advantages. By this definition, the scalar product of a vector by itself is the square of its length or magnitude as Sah defines it, and is never negative, and is zero only when all the components of the vector are zero. If we call 2 vectors mutually perpendicular when their scalar product thus defined is zero, then no vector is perpendicular to itself. In 3-dimensional complex space a set of no more than 3 mutually perpendicular unit vectors can be found. If $I$, $J$, $K$, are any 3 such mutually perpendicular unit vectors, and if $X$ is any vector, then $X = (I \cdot X)\ I + (J \cdot X)\ J + (K \cdot X)K$ if this definition of scalar product is used.

Vector space with complex components and with this definition of the scalar product is much used in quantum mechanics. It is called unitary space, and has many properties similar to those of Euclidean space. A good account of unitary space is given in Weyl's "Group Theory and Quantum Mechanics."

With this definition of scalar product, the unit vectors $u$, $f$, $b$ in Sah's paper, which represent unit symmetrical components (divided by $V\bar{3}$) become mutually perpendicular. The transformation to symmetrical components becomes a "unitary" transformation which may be regarded as a generalization of the "orthogonal" transformation in real space, that is a rigid rotation of orthogonal axes.

**Irven Travis** (University of Pennsylvania, Philadelphia): The statements in this discussion are restricted to *linear* networks. In such networks the calculation of the currents resolves itself into the calculation of the values of the $I$'s in a set of equations of the form

$$\left.\begin{aligned} Z_{11}I_1 + Z_{12}I_2 + \ldots + Z_{1n}I_n &= V_1 \\ Z_{n1}I_1 + Z_{n2}I_2 + \ldots + Z_{nn}I_n &= V_n \end{aligned}\right\} \quad (1)$$

Methods of evaluating the $Z$'s in a particular problem are well known. If the calculation of the $I$'s is to be rendered simpler than seems to be indicated by these equations some scheme must be devised to circumvent the indicated algebraic work. Any such scheme, however, must ultimately express the $I$'s in terms of the $V$'s; or at least certain known functions of the $I$'s in terms of certain known functions of the $V$'s. Methods for accomplishing this have been variously described as vector, tensor, dyadic, matrix, etc, methods. It seems that the success of any of these schemes for simplification must depend upon special properties of the array

$$\left.\begin{aligned} Z_{11}Z_{12} \ldots Z_{1n} \\ Z_{n1}Z_{n2} \ldots Z_{nn} \end{aligned}\right\} \quad (2)$$

(Conventional bars are not placed on this array nor is any name assigned to it lest

the writer's position be prejudiced.)

If the array (2) has special properties, as for example symmetry, *any* system designed to take advantage of these properties will meet with success. It the array has no special properties the various schemes suggested amount to statements of the same problem in terms of different notations and no particular advantage accrues to any one.

In January 1933, it was suggested to the writer by Carl Chambers, then a graduate student at the Moore School, that the Stokvis-Fortescue transformation could be expressed in matrix form more simply than in terms of the "sequence operators" used in Fortescue's 1918 paper. A matrix formulation for 3-phase circuits was developed, in which the matrix

$$\frac{1}{3}\begin{Vmatrix} 1 & 1 & 1 \\ 1 & a & a^2 \\ 1 & a^2 & a \end{Vmatrix} \qquad (3)$$

and its inverse

$$\begin{Vmatrix} 1 & 1 & 1 \\ 1 & a^2 & a \\ 1 & a & a^2 \end{Vmatrix} \qquad (4)$$

play an important part. After having been used in mimeographed form in the senior machinery course at the Moore School for 3 years this method of presenting symmetrical components was included in section 3 of the "Electrical Engineer's Handbook," Pender-DelMar, John Wiley and Sons, 1936. I was very much interested in Sah's paper as several of his expressions from the vector viewpoint are in complete agreement with similar expressions obtained from the matrix viewpoint.

However, neither the vector nor the matrix presentation has any virtue other than neatness of notation and clarity of expression. Any simplification in actual calculation of any given problem must be due to symmetry in the impedance matrix of the system. If there is no symmetry there can be no simplification.

From a pedagogical view point it is highly desirable to use some scheme which systematizes an analysis and correlates all calculations of a given class. Special cases are given added clarity if they appear as special cases of a general formulation rather than as isolated and unrelated problems. It is in this aspect and not in reduction in actual labor of calculation that tensors and matrices are of value in electrical engineering.

C. E. Rose (Federal Emergency Administration of Public Works, Washington, D. C.): Believing that the following discussion of the article, entitled, "Dyadic Algebra Applied to 3-Phase Circuits," by A. Pen-Tung Sah, which appeared in the August issue of ELECTRICAL ENGINEERING, may be helpful to others interested in the applications of dyadics and tensors to the solution of electrical problems, I submit the following:

A dyad is nothing more or less than the product of 2 vectors written as $AB$, and the symbolic sum of a number of dyads is a dyadic.

A matrix is a system of related but independent quantities whereas a determinant is either a real or complex number, or zero.

Therefore equation 28*d*, page 881 in this article is presented incorrectly, due probably to a typographical error. It is written as:

$$(\sqrt{3}u \times Z_m)_{2s} = j\begin{Vmatrix} -2.20 & -3.42 \\ 7.90 & 2.12 \end{Vmatrix} + j\begin{Vmatrix} 2.12 & 1.46 \\ 1.30 & 0.08 \end{Vmatrix} + j\begin{Vmatrix} -2.20 & -1.54 \\ -5.70 & 0.08 \end{Vmatrix}$$

the right-hand side of which is expressed as the sum of 3 dyadics of rank 2, whereas it should have been written as:

$$(\sqrt{3}u \times Z_m)_{2s} = \begin{vmatrix} -2.20 & -3.42 \\ 7.90 & 2.12 \end{vmatrix} + \begin{vmatrix} 2.12 & 1.46 \\ 1.30 & 0.08 \end{vmatrix} + \begin{vmatrix} -2.20 & -1.54 \\ -5.70 & 0.08 \end{vmatrix} = -11.66$$

because it is the sum of 3 determinants of rank 2, and involves neither a matrix nor a dyadic and is numeric only.

Again, equation 19, page 880, is written as:

$$Y = \begin{Vmatrix} y_{aa} & y_{ab} & y_{ac} \\ y_{ba} & y_{bb} & y_{bc} \\ y_{ca} & y_{cb} & y_{cc} \end{Vmatrix} = Z^{-1} = \frac{1}{D}\begin{Vmatrix} (z_{bb}z_{cc} - z_{bc}z_{cb}) \cdots\cdots\cdots\cdots \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ \cdots\cdots\cdots\cdots (z_{aa}z_{bb} - z_{bb}z_{ba}) \end{Vmatrix}$$

It is not necessary when writing a tensor equation, which contains only electric tensors, to define the voltages under consideration, as covariant tensors which they are, but when once a convention has been established as it is in this article by equation 1, page 876, which is written as:

$$e_a = z_{aa}i_a + z_{ab}i_b + z_{ac}a_{ac}i_c, \text{ etc.}$$

and which properly defines the voltages as a covariant tensor of rank 1, and the impedances as a covariant of rank 2, then it is thought that the admittance $Y$ would be better defined as a contravariant tensor of rank 2, because this corresponds to reality in which case we would write:

$$Y = \begin{Vmatrix} y^{aa} \cdots\cdots\cdots\cdots\cdots\cdots \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ \cdots\cdots\cdots\cdots\cdots\cdots y^{aa} \end{Vmatrix} = Z^{-1}$$

The matrix $Z^{-1}$, which is the inverse of matrix $Y$ is obtained from it by replacing each element of the $Y$-matrix by its cofactor, with the superscrips changed to subscrips and permuted once, divided by the determinant of the $Y$-matrix because

$$Y^{ik} = Z_{kl}{}^{-1}$$

namely it is a skew-symmetric tensor, and is nothing more than the vector product of 2 generalized vectors. Thus if we write vectorially:

Vector $A$ times vector $B = A \cdot B + A + B$, the last term is really a skew-symmetric tensor of rank 2, which is written in tensor form as:

$$A_{ik} = A_{kl}$$

The simplest matrix which we encounter is the co-ordinate of a point in 2-dimensional space as $(X, Y)$.

The "scalar of the second" used in this article is simply

$$\phi_2 = (\phi_s)_2 = A_{11} + A_{22} + A_{33}$$

in which $A_{11} \ldots A_{33}$ are the elements of the principal diagonal of the inverse for the matrix under consideration. The matrix:

$$\begin{Vmatrix} 0 & -1 & 1 \\ 1 & 0 & -1 \\ -1 & 1 & 0 \end{Vmatrix}$$

which appears several times in this article is nothing more or less than:

$$\begin{Vmatrix} ii & ij & ik \\ ji & jj & jk \\ ki & kj & kk \end{Vmatrix}$$

obtained by combining the 3 unit vectors, 2 at a time, into dyads multiplied by $-1$.

Professor Gibbs, part of whose theorems A. Pen-Tung Sah employed, proved that a dyadic $\phi$ possessed 3 scalar invariants; namely

$$\phi_1 = a_{11} + a_{22} + a_{33}$$
$$\phi_2 = A_{11} + A_{22} + A_{33}$$
$$\phi = \begin{Vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{Vmatrix}$$

A transpose is a dyadic, or matrix, which is obtained by interchanging rows and columns. The simplest definition of a tensor is, I believe; that if the 9 quantities:

$$\begin{Vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{Vmatrix}$$

possess the property that when written as

$$\sum_{ik} a_{ik}a_ib_k = a_{11}a_1b_1 + a_{21}a_1b_2 + a_{13}a_1b_3 \ldots$$

is invariant to any arbitrary rotation of the Cartesian co-ordinate system, wherein $A$ and $B$ are any arbitrarily chosen vectors, then this last matrix presented above is a tensor. This definition also yields a simple method to test for the existence of a tensor by subjecting it to a rotation and if, after simplifications, it returns to the identical original form we know that it is a tensor.

# An Analysis of the Shaded-Pole Motor

**Discussion and author's closure of a paper by P. H. Trickey published in the September 1936 issue, pages 1007-14, and presented for oral discussion at the induction machinery session of the winter convention, New York, N. Y., January 27, 1937.**

Selby Haar (Board of Transportation, City of New York, N. Y.): Emphasis has been laid on the small rating of the usual shaded-pole motor. Have you ever observed with these motors that the current at fractional loads is less than at no load?

G. G. Veinott (Westinghouse Electric & Manufacturing Company, Springfield, Mass.): Trickey has presented an illuminating analysis of a type of motor of great commercial importance, and his analysis is probably the first of its kind ever presented before AIEE on this important

motor. The "shading principle," that is the action of a short-circuited coil placed around a portion or all of a magnetic circuit, is a familiar one; it is used in damper or amortisseur windings of synchronous machines, it is used in watt-hour meters, a-c contactors and in many other places.

Once when studying damper windings, I discovered some fundamental equations of the damped magnetic circuit which were most helpful quantitatively and qualitatively. So far as I know, these equations and concepts are original and I am now publishing them for the first time because of the light they throw upon the principle of the shading coil.

The conventional method for analyzing a damped magnetic circuit is to compute the current induced in the damping coil by the changing flux and subtract the magnetomotive force due to this current from the primary-exciting magnetomotive force, obtaining a resultant magnetomotive force; from this resultant magnetomotive force is calculated the flux, which in the case of an a-c supply, is assumed to be proportional to and in phase with this resultant magnetomotive force.

A-c circuits containing resistance and inductance could be solved in an analogous manner by computing the voltage induced in the inductance, subtracting it from the impressed voltage, obtaining a resultant voltage; the current would then be proportional to, and in phase with this resultant voltage. It has been found more convenient to analyze such circuits by introducing the concent of reactance, which might be termed a "quadrature resistance." The method of analyzing a damped magnetic circuit which I am about to outline is exactly analogous to the conventional method of treating a-c circuits; in it I introduce a concept of what might be termed "quadrature reluctance" since, in the magnetic circuit, it bears the same relation to reluctance that inductive reactance does to resistance in an electrical circuit.

The fundamental equation for the instantaneous value of flux in a magnetic circuit of reluctance $\mathcal{R}$ excited by a sine-wave magnetomotive force, $m = M_m \sin \omega t$, and interlinked by an electrical circuit of $N$ turns having an ohmic resistance of $r$ ohms and no leakage inductance, can be shown to be

$$m = \phi\mathcal{R} + \frac{4\pi n^2}{r \cdot 10^9}\frac{dq}{dt} = M_m \sin \omega t \qquad (1)$$

Now let,

$$\frac{4\pi n^2}{r \cdot 10^9} = \mathcal{L} \qquad (2)$$

Then equation 1 becomes

$$m = \phi\mathcal{R} + \mathcal{L}\frac{d\phi}{dt} = M_m \sin \omega t \qquad (3)$$

The fundamental equation of an a-c circuit containing resistance and self-inductance is

$$e = Ri + L\frac{di}{dt} = E_m \sin \omega t \qquad (4)$$

Equations 3 and 4 are seen to be identical in mathematical form. Since these differential equations are identical in form, the solutions must also be identical in form and therefore, we may write at once (or solve equation 3 if we wish)

$$\phi = Ce^{-\frac{\mathcal{R}}{\mathcal{L}}t} + \frac{M_m}{\sqrt{\mathcal{R}^2 + (\omega\mathcal{L})^2}} \sin(\omega t - \theta) \qquad (5)$$

or, neglecting the transient term, the root-mean-square value of flux is

$$\Phi = \frac{M}{\sqrt{\mathcal{R}^2 + (\omega\mathcal{L})^2}} \qquad (6)$$

and the flux $\Phi$ lags behind the exciting magnetomotive force by an angle

$$\theta = \cos^{-1}\frac{\mathcal{R}}{\sqrt{\mathcal{R}^2 + (\omega\mathcal{L})^2}} \qquad (7)$$

Thus, it can be seen that a damper coil affects a magnetic circuit the same way self-inductance affects an electric circuit, even so far as transient effects are concerned. That is to say, in a-c magnetic circuit, a damper or shading coil reduces the effective a-c component of flux and causes this flux to lag behind the exciting magnetomotive force.

Nearly all elementary text books refer to the Ohm's law of the magnetic circuit. Likewise, all a-c textbooks extend the Ohm's law of the d-c circuit to the a-c circuit by using a "quadrature resistance" or reactance in combination with resistance. None of them, apparently, extend the "Ohm's law of the magnetic circuit" to damped magnetic circuits excited by alternating current. I would propose to do so by introducing a few new terms which I list below; those terms in *italics* are of my own invention.

Thus, the angle of lag of the flux in a shading coil, behind the flux in the unshaded portion is

$$\theta = \cos^{-1}\frac{\mathcal{R}}{\sqrt{\mathcal{R}^2 + (\omega\mathcal{L})^2}} \qquad (7)$$

$$= \cos^{-1}\frac{\mathcal{R}}{\sqrt{\mathcal{R}^2 + \left(\frac{8\pi^2 n^2 f}{r \cdot 10^9}\right)^2}} \qquad (8)$$

Moreover, in a damped magnetic circuit, the ratio of the damped flux, to that which would exist with no damping is given by the equation

$$\cos\theta = \frac{\mathcal{R}}{\sqrt{\mathcal{R}^2 + (\omega\mathcal{L})^2}} \qquad (9)$$

Equation 9 might be called the damping factor.

The foregoing analysis has been given because of the light it throws on the principle of the shading coil. It does not contradict any point of Trickey's analysis but will, I hope, help to explain how a shading coil reduces the flux and causes it to lag behind its magnetomotive force producing in effect a sort of makeshift rotating field in a shaded pole motor.

It is to be noted that this method of analysis automatically eliminates one variable, namely, the current in the shading coil. Perhaps, by using this concept, Trickey could reduce his analysis to 3 simultaneous equations, instead of 4 as he now has. This is merely offered as a suggestion which may or may not be of value.

Trickey has compared the performance of the shaded pole motor with the split-phase motor with no starting switch. In the light of the foregoing analysis, an interesting comparison can be made between these types of motors. In both types there are 2 magnetic fields set up approximately 90 degrees apart in space. In both motors these fields are displaced slightly in time. In both motors these fields are each set up as a result of the same single-phase electromotive force. In both types of motors, it may be said, there are 2 magnetic circuits. But herein lies the difference: in the split-phase motor there are 2 magnetomotive forces displaced in time phase from each other acting on similar magnetic circuits, so the fluxes are displaced by the same phase angle as the magnetomotive forces; in the shaded-pole motor there is only one magnetomotive force acting upon 2 magnetic circuits in parallel and the phase displacement in fluxes is due to dissimilarity in the magnetic circuits. Thus, it is scarcely to be wondered that the performance of the 2 types of motors should be similar.

**P. H. Trickey:** It is quite possible for a shaded-pole motor to have less input under load than at no load. In fact, the losses of shaded-pole motors very often decrease with load. If the motor is highly saturated, this will sometimes result in an actual decrease in watts input in going from no load to full load.

Veinott's discussion is very interesting, and it seems to me to have possibilities in handling the difficulties of shaded pole circuits. In this case of the shaded pole motor, if it will result in the reduction in the number of variables from 4 to 3 even at the expense of adding another constant or two, it will probably make possible a much more satisfactory solution.

| Electric Circuit | | Magnetic Circuit | |
|---|---|---|---|
| Electromotive force | $E$ | Magnetomotive force | $M$ |
| Current | $I$ | Flux | $\Phi$ |

**Discussion of papers by A. Boyajian, L. V. Bewley, and Gabriel Kron published in the August 1936 and November 1936 issues and presented for oral discussion at the tensor analysis session of the winter convention, New York, N. Y., January 26, 1937.**

**W. E. Byrne** (nonmember; Virginia Military Institute, Lexington): One of the best ways in which to find out what is contained in a newly organized theory is to teach the material. During the first term of this school year I have given a course one hour a week on vector analysis, polyadics, matrices and tensors to a small group of students and instructors. As an application of these mathematical topics I took up the first 2 papers of Kron (*General Electric Review*, 1935). Naturally such applications are not as general as the basic mathematical theory since the connection matrices are specialized, in that the elements are merely $-1$, $+1$, and 0. Kron and others working in this field are to be commended for developing such powerful and general methods of attacking problems of electrical engineering. It is interesting to note that engineers and mathematicians promise to have more and more in common in the future.

**M. G. Malti** (Cornell University, Ithaca, N. Y.): If we look back to the early records of the use of the algebra of complex numbers in connection with electrical-engineering problems we would find that the problems of those days (early twentieth and late nineteenth century) are just as readily solvable with as without the use of complex numbers. The introduction of complex numbers into engineering paved the way for a deeper, more comprehensive and more forceful analysis of these and later problems.

I shall go a step further and state that most of the early problems were too simple to require more than the mere algebra of complex numbers. The application of the theory of functions of complex variables to electrical-engineering problems was unheard of in those days. Now, within the life span of those who witnessed the first introduction of the algebra of complex numbers, we see a rather common use of the theory of fuctions of complex variables in connection with operational analysis, Laplace and Fourier Transforms, etc.

There was little sympathy and no understanding shown to those select few who used the albegra of complex numbers in the early days. Little sympathy is shown now to those who talk of Laplace transforms and contour integration and downright opposition to those who dare mention tensors.

It is undoubtedly true that our present engineering problems do not call for tensor analysis. But who can predict that the engineers of the future will not need tensor analysis to solve their problems? Any engineer who 30 years ago dared make the statement that engineers would have to become thoroughly acquainted with mathematical works on functions of complex variables to solve their knotty theoretical problems of network analysis would have been laughed at. But here we are today using these works most effectively in circuit analysis.

I make these statements more to express a point of view than to support one faction or another. We all agree that it is impossible to guess what the problems of the future will be and what type of analysis these problems will require. Hence it behooves us to view with sympathy and understanding all work of an advanced nature in the hope that, if it is not immediately useful, it might prove to be so in the future.

**M. F. Gardner** (Massachusetts Institute of Technology, Cambridge): The linear algebraic transformation expressing the element currents $i^k(t)$ in terms of the loop currents $i^\alpha(t)$ in a connected network is

$$i^k(t) = C_\alpha{}^k i^\alpha(t) \tag{1}$$

in which $C_\alpha{}^k$ is the connection matrix, and in which the $k$ and $\alpha$ run over the elements and loops, respectively.

The linear equations expressing the envarience of the total instantaneous power $p(t)$ under transformation from element variables $[i^k(t)$ and $v_k(t)]$ to loop variables $[i^\alpha(t)$ and $\bar{v}_\alpha(t)]$ is

$$p(t) = v_k(t) i^k(t) = v_\alpha(t) i^\alpha(t) \tag{2}$$

If the voltages and currents are sinusoidal—and only steadystate relations are of interest— the $i$'s of equation 1 can be replaced by their complex amplitudes. With the $i$'s of (2) replaced by their complex amplitudes, the $v$'s must be replaced by the conjugates of their complex amplitudes. The $p$ is then replaced by the so-called "vector power." This use of conjugate complex amplitudes works satisfactorily for this particular case—the steady state with sinusoidal functions or sums of sinusoidal functions.

Barnes (of Tufts College) and I have noted that the use of conjugate complex amplitudes in this way does not carry over to the case of transients, which involve nonperiodic functions. Since we have not seen a satisfactory statement in the literature of a generalization to cover such cases, we shall indicate one here.

Before we can state the essential idea of this extension it perhaps will be helpful to make a few preliminary remarks about the Laplace transformation (hereafter abbreviated $L$-transformation) by which the extension will be made.

Let $s = \sigma + j\omega$ be a complex variable corresponding to the real variable $t$. Then a general time function $f(t)$ can be transformed into its corresponding generalized frequency function $F(s)$ if $f(t)$ is given and is such that the following definite integral is absolutely convergent,

$$\int_0^\infty f(t) e^{-st} dt = F(s) \qquad c_a < \Re(s) \tag{3}$$

This integral defines $F(s)$ for that part of the complex $s$-plane wherein the real part of $s$ is sufficiently great to insure the integral having a finite value.

If, on the other hand, $F(s)$ is the function known and the corresponding $f(t)$ is unknown, (3) becomes an integral equation, but its solution is given by the integral

$$\frac{1}{2\pi j}\int_{c-j\infty}^{c+j\infty} F(s) e^{ts} ds = f(t) \quad 0 < t \quad c_a < c \tag{4}$$

This is a line integral in the complex plane. The path of integration is a straight line paralleling the axis of imaginaries and lying in that part of the $s$-plane in which $F(s)$ is defined.

The integrals of (3) and (4) constitute, respectively, the direct $L$-transformation and its inverse. Further, an $f(t)$ and its $F(s)$ constitute an $L$-transform pair and can be written as

$$f(t) \qquad F(s) \tag{5}$$

For application of these ideas in the present discussion it is necessary to know that, given 2 $L$-transform pairs

$$\left.\begin{matrix} f_1(t) & F_1(s) \\ f_2(t) & F_2(s) \end{matrix}\right\} \tag{6}$$

the pair which results when the 2 *time* functions are multiplied is

$$f_1(t)\, f_2(t) \frac{1}{2\pi j}\int_{c_1-j\infty}^{c_1+j\infty} F_1(w) F_2(s-w) dw$$

$$\left.\begin{matrix} c_{a_1} < c_1 \\ c_{a_2} < \Re(s-w \end{matrix}\right\} \tag{7}$$

For interpretation of this it is helpful to have also the pair which results when the 2 *frequency* functions are multiplied. This pair is commonly found in engineering literature. It is

$$\int_0^t f_1(\tau) f_2(t-\tau) d\tau \qquad F_1(s)\, F_2(s) \tag{8}$$

Pairs (7) and (8) can be abbreviated by introducing the notation

$$f_1(t)\, f_2(t) \qquad F_1(s) * F_2(s) \tag{7a}$$

$$f_1(t) * f_2(t) \qquad F_1(s)\, F_2(s) \tag{8a}$$

In (7) the integration in the complex $w$-plane is along a straight line paralleling the axis of imaginaries and lying in that part of the $w$-plane in which $F_1(w)$ is defined. In (8) the integration is along the positive time axis. In both integrals the functions are said to be convolved. In (8) the $f_2$ function is "folded" before multiplication by the $f_1$ function. In (7) the $F_2$ function is rotated by 180 degrees and shifted by the amount $s$ before multiplication by the $F_1$ function. Various forms of the convolution integral for functions of real variables shown in (8) are referred to in the engineering literature as Borel's integral, Duhamel's integral, and the superposition integral. For frequency functions, the counterpart of this superposition-type in-

tegral is the complex convolution integral appearing in (7).

Applying these ideas now to the original equations 1 and 2, each member is transformed by use of (3), i.e., each member is multiplied by the exponential $e^{-st}$ and integrated from 0 to $\infty$. Equation 1 transforms to

$$I^k(s) = C_\alpha{}^k \hat{I}^\alpha(s) \qquad (9)$$

Equation 2 presents cases of time-function products. In their transformation (7*a*) is used. The result is

$$P(s) = V_k(s) \quad I^k(s) = v_\alpha(s) * \hat{I}^\alpha(s) \qquad (10)$$

Each typical term in (9) and (10)—instead of being a function of $t$ as in (1) and (2)—is a function of $s$. The currents, voltages, and power involved may be any functions of time, provided only that they are $L$-transformable by (3). When it is necessary to return to functions of time, the inverse transformation (4) is used.

It should not be concluded from what has been said here that in practical work it is advisable, even though possible, to replace the simple operation of multiplication by the complicated operation of convolution (*). But in theoretical work it may be very convenient to make this replacement, especially when it is not necessary to actually carry out the indicated convolution.

Summarizing, for theoretical work utilizing tensor or matrix notation a scheme is provided for handling general time functions by means of their $L$-transforms much as sinusoidal functions are now treated by means of their complex amplitudes. The condition remaining which these time functions must fulfill is that they be $L$-transformable. In addition to furnishing a generality needed for theoretical work, the transform method provides a compact symbolism which fits conveniently into the tensor or matrix scheme of notation.

**W. H. Ingram** (nonmember; New York, N. Y.): On page 1220 the author mentions a "first generalization theorem" and says that by the use of the notation advocated the behavior of the most complex systems are "described' by the application of the theorem to equations of motion governing the simplest of all systems, namely, that of one degree of freedom.

This should be a theorem of great importance, as its statement and the italics used would suggest, but on examination it would appear to be merely a statement that from the equation $e = Zi$ governing a simple system we can deduce the equation $e_n = Z_{nm}i^m$ for a more complex system although, presumably, the fact that the ordinary equation

$$e_n = \Sigma Z_{nm} i_m$$

rests in some way on the simpler one is not claimed as requiring the new theorem.

If this is the generalization claimed, we are brought immediately to the question of what a tensor is and what bearing the concept of a tensor has on the solution of network, machine and vacuum-tube problems.

To begin with, a tensor has no meaning except in reference to, or conjunction with, *admissible co-ordinate systems*. Not all co-ordinates used by electrical engineers come under this head: the co-ordinates used by Blondel and Park, among others, in the theory of electrical machines, do not. To prove this, take, for example, the expression

$$ds^2 = g_{ij} dq^i dq^j$$

called the Riemannian *metric* in certain geometrical interpretations of dynamics and connected with the kinetic energy. The coefficient $g_{ij}$ is a tensor because of the fact that

$$g_{ij} = g_{\alpha\beta}{}^* \frac{\partial q^\alpha}{\partial q^i} \frac{\partial q^\beta}{\partial q^j}$$

*when* the $q$'s with Latin superscripts and those with Greek form 2 admissible co-ordinate systems. Given the first system, a second can always be obtained by a linear transformation, that is, of the form

$$q^i = b_j{}^i q^{*j}$$

as a matter of fact, an infinite number of admissible systems exist in this case.

However, in the theory of electrical machinery, transformations of the form

$$dq^i = \beta_\alpha{}^i dx^\alpha$$

occur where the $dx$'s are the differentials of quasico-ordinates and where the right-hand side is a not completely integrable Pfaffian so called, that is, the right-hand side is not a complete differential. Substitute this last equation into the formula for the metric and we obtain

$$ds^2 = g_{\alpha\beta}{}^* dx^\alpha dx^\beta$$

so that

$$g_{ij} = g_{\alpha\beta}{}^* \frac{\partial \dot{x}^\alpha}{\partial \dot{q}^i} \frac{\partial \dot{x}^\beta}{\partial \dot{q}^j}$$

where $\dot{x}$ is the total derivative of $x$ with respect to the time or any other parameter. This last expression is *not* in agreement with the rule for the transformation of a covariant tensor of the second order. Hence the $x$'s, which include the co-ordinates introduced by Blondel and which are indispensable in the theory of electrical machinery, do *not* form an admissible co-ordinate system.

The functions $\beta_1{}^i, \beta_2{}^i \ldots \beta_n{}^i$ are regarded by geometers as the components of a covariant vector, in the manifold of the $q$'s, tangent to a congruence of the curves defined by the equations

$$\frac{dq^1}{\beta_i{}^1} = \frac{dq^2}{\beta_i{}^2} = \ldots = \frac{dq^n}{\beta_i{}^n}$$

and the $dx$'s, given by $dx^i = \alpha_j{}^i dq^j$, may be interpreted as the differential co-ordinates of a neighboring point in the associated space of the tangents mentioned and forming a Cartesian reference system. A different system of congruences chosen in the $q$-space gives a different associated space and this is also so in general when there is a metric defining the associated space.

In the present case the metric in question would be $g^*$, the $x$'s referring to arcs of the congruences, and the associated space is Riemannian. But no tensor discussion involving this space is possible except when based upon the underlying $q$-system of co-ordinates. In other words, no tensors occur in, or can enter, the theory of any commutator machine until the latter is regarded as a transform of a slip-ring machine and then only with reference to the true co-ordinates involved.

When the commutator machine has fewer degrees of freedom, certain $dx$'s are identically zero and the theory of nonholonomic metrical subspaces comes in. (Vranceanu, "Les espaces non-holonomes," Paris, 1936 page 18.)

The question has been suggested: can tensors enter the congruence space via the asymmetric "coefficients of affine connection" of ultra Riemannian geometry and, if so, has that fact any bearing on the theory of electrical machines and circuits? It is known (Eisenhart, "Non-Riemannian Geometry," page 14) that the paths of the manifold corresponding to geodesics of a Riemannian space are given by the curves defined by the equation

$$\dot{q}^j(\ddot{q}^i + \Gamma^i{}_{kl}\dot{q}^k\dot{q}^l) - \dot{q}^i(\ddot{q}^j + \Gamma^j{}_{kl}\dot{q}^k\dot{q}^l) = 0$$

where

$$2\Gamma^i{}_{jk} = L^i{}_{jk} + L^i{}_{kj}$$

provided $L^i{}_{jk}$ transforms according to the fundamental equation

$$\frac{\partial^2 q^i}{\partial \bar{q}^\alpha \partial \bar{q}^\beta} + L_{jk}{}^i \frac{\partial q^j}{\partial \bar{q}^\alpha} \frac{\partial q^k}{\partial \bar{q}^\beta} = \bar{L}_{\alpha\beta}{}^\gamma \frac{\partial q^i}{\partial \bar{q}^\gamma}$$

Now we cannot take

$$L^r{}_{jk} = g^{*rs}\Lambda_{jk,s}$$

as has been done (Kron, "Non-Riemannian Dynamics of Rotating Electrical Machinery," *Journal of Mathematics and Physics*, volume 13, 1934, page 156) for the $x$'s would appear in place of the $q$'s in this last equation and the existence of the derivatives $\partial x^i/\partial \bar{x}^\alpha$ cannot be established. A search for a more suitable "coefficient" might be in order if no metric were available, but in the theory of electrical machines and circuits a metric is always at hand and the geometry of the dynamics of electrical machinery and circuits is in fact ordinary Riemannian, as I have remarked elsewhere (*Bulletin* of the American Mathematical Society, September 1934, page 666). This, I gather, is also the opinion of Synge ("Tensorial Methods in Dynamics," University of Toronto Press, 1936).

The author calls $C_m{}^\alpha$ a "transformation tensor." The transformations involved are of such a special kind that the name used may be misleading. Consider the system of seven variables $x_1, x_2 \ldots x_7$ upon which 2 conditions are imposed, say the conditions that the equations $x_1 - x_2 + x_3 - x_5 = 0$ and $x_2 - x_3 + x_4 - x_7 = 0$ be satisfied. We can solve these equations for 2 of the variables, say $x_6$ and $x_7$. The remaining variables may be thought of as the independent ones and we may wish to designate them by special letters, say $y_1, y_2 \ldots y_5$. Hence we may write $x_1 = y_1$, $x_2 = y_2$, $x_3 = y_3$, $x_4 = y_4$, $x_5 = y_5$, $x_6 = y_1 - y_2 + y_3$, $x_7 = y_2 - y_3 + y_4$. The matrix of this "transformation" (it will be noted that there is no inverse) happens to be the author's matrix (48) in this case. The original 7 $x$'s could represent the currents in 7 parts of a net and the equations of condition could represent the application of Kirchhoff's law at 2 junction points: the $y$'s would then represent the currents in

*complete* circuits. This and many related topics are adequately expounded by Quade ("Klassifikation der Schwingungsvorgaenge in gekoppelten Stromkreisen," Leipzig, 1933) in terms of matrices. Redundant constraints, detectable by the rank of the Jacobian involved, are treated in the same way.

The fact that there are many ways of eliminating 2 of the $x$'s ordinarily would not be interpreted as bringing in as many admissible co-ordinate systems in the tensor sense particularly in the case where the $x$'s are the differentials of quasico-ordinates. Tensors come in only when the co-ordinates in one admissible co-ordinate system are related one-to-one to those in another, when the functional relation between them is of class $C^m$ (that is, having continuous partial derivatives up to and including the $m$th order, $m \geqslant 1$), and when the functional Jacobian is not equal to zero. If tensors really were being considered here, Quade's circuitization matrix would contain functions, that is, (48) would contain partial derivatives of one set of co-ordinates with respect to another admissible set instead of the 0's and 1's shown. The author's 2 paragraphs between equations 20 and 21 would appear to be therefore erroneous.

To sum up the discussion above as it bears on the question of tensors, the situation would seem to be that to date tensors have not been brought into the theory of electrical nets and machines. When this has been done, the question of their usefulness will be less difficult to settle.

Equations 41 and the discussion of figure 3 would appear to be new developments, but on close inspection the addition theorem given by (41) is found to be quite trivial because of the fact that both the circuitizing matrix $C$ and the impedance matrix of (*a*) and (*b*), figure 3, have to be of the same order. One does not know how to write down either of these matrices for (*b*) unless the order of the impedance matrix of the system that is to be connected at $g_2$ and $p_2$ is known in advance.

In the paper by L. V. Bewley the author implies that his method $C$ is dynamical but his use of the terms "ignoration," "constraint," and "canonical" seem to be at variance with the meanings of these expressions in classical dynamics. No co-ordinate is "ignorable" in dynamics when there is dissipation involved, a force polygon being closed implies no constraint and the canonical equations in dynamics are equations of motion in terms of the displacements and momenta as variables exclusively. The equation

$$e_k = z_{kl} i^l$$

or its equivalent, was called more appropriately the "generalized Ohm's Law" by Kennelly.

The author says that the "connection tensor" $C_\alpha^j$ expresses old currents "before interconnection" in terms of new currents "after interconnection." The false impression may be conveyed that there is a physical rearrangement of the net to correspond to the mathematics, or vice versa. Both the "old" currents and the "new" currents must refer to the same system arrangement: in the first case to where the variables are not independent and in the second case to where redundant variables have been eliminated by algebraic processes. The theory has been given matrix form by Quade and others and the above mentioned "connection tensor" appears to be nothing more than Quade's circuitizing matrix.

Given a system of circuit segments or meshes arranged in the form of a net, with or without inductive coupling, and specified by the kinetic energy, the potential energy, the Rayleighean dissipation and the external work functions, Quade ("Klassifikation der Schwingungsvorgaenge in gekoppelten Stromkreisen," Leipzig, 1933) has shown (*a*) how force equations free from Lagrangean multipliers can be obtained in a more fundamental manner than usual, (*b*) how the operational determinant or matrix of a system classifies it on the basis of the elementary divisors of the determinant, and (*c*) the significance of *representatives* of the classes in question, which are exhaustively studied. The author's first transformer circuit (windings in series), load-ratio control circuit, and forked auto-transformer circuit come under one or other of these classifications.

The author's procedure differs from Quade's in 2 minor respects: the use of equations of ampere-turn balance and the inclusion of the electromotive forces $e_0$, $e_1$, etc. Some of these electromotive forces are not truly external but are reactive (with one sign or another) which it is necessary to introduce together with the equations of ampere-turn balance when any of the mutual inductances are left out of the analysis. This procedure seems to be necessary when it is desired to take into account excitation losses (which the author does not do) but otherwise the method adopted by Quade would seem to be simpler. Quade's method of finding the external forces acting in the circuits, given those acting in the meshes, can hardly be improved upon for simplicity (cf. ibid. ¶18).

As the author's discussion is really one in terms of matrices it is not clear how tensors come in at all. The use of tensor notation is one thing, to have a tensor enter is another. Bôcher used vector notation for matrices but that does not make them vectors. On the other hand, we may have tensors without using tensor notation as is evidenced by the fact that the German mathematician Voigt, who originated the idea of a tensor, never omitted the summation sign, as is now done, and did not use dummy indices. There seems to be nothing against the use of tensor notation, except perhaps that it is too condensed, but if it is used it seems reasonable to demand that tensors really be involved in the discussion.

**V. Karapetoff** (Cornell University, Ithaca, N. Y.): Tensor analysis has been proved to be a powerful tool in the solution of quite advanced electrical problems; it is of interest to note, however, that some simpler problems involving stationary networks require only matrix algebra. This means that students of the subject may be able to solve a certain class of problems without going into the general theory of invariants. In particular, it has been felt that some of the earlier treatment in Kron's epoch-making articles in the *General Electric Review* (volume 38, page 231) could be developed in greater detail and shown to agree with Kirchhoff's law, without explicitly using power as an invariant.

Let figure 1 represent a stationary network with impedances and sources of voltage (indicated by small circles) in each branch. Only instantaneous values of the currents and the voltages will be considered, so that it is immaterial whether the inserted voltages are direct or alternating, and whether the régime is steady or transient. The individual conductors (or branches) are denoted by the letters $a, b, \ldots . n, p$. The positive directions of the currents in the individual branches are arbitrary and are indicated by arrowheads. An applied voltage in a branch is to be considered positive if it tends to produce a current in the positive direction in that particular branch.

Following Maxwell (*Electricity and Magnetism*, volume 1, page 406), fictitious mesh currents, $x, y, z, t, u, v$, are introduced, with the positive directions arbitrarily taken clockwise. These currents are supposed

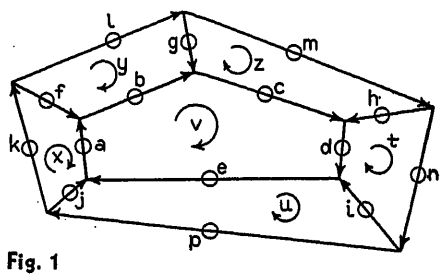

Fig. 1

to circulate in the individual loops of the network; an actual branch current is an algebraic sum of the corresponding mesh currents. For example, the current in $a$ is equal to $v - x$. It is well known that in this manner Kirchhoff's first law is satisfied automatically and need not be expressed by separate equations. We shall use the following notation and terminology:

The individual conductors (or branches), the currents flowing through the same, and the inserted (or applied) voltages will all be denoted by the same symbols, $a, b, c, \ldots n, p$. No confusion need arise as to whether a current or a voltage is meant, or the conductor itself. The potential differences between the terminals of the respective conductors will be denoted by the corresponding capital letters, $A, B, C, \ldots N, P$. The letters $x, y, z, t, u, v$, will mean interchangeably the respective loops or meshes, the fictitious currents circulating around these meshes, and the sums of the applied voltages in the same meshes. Those sources of voltage which give a positive energy output with the corresponding mesh currents are to be considered positive, when summing up around that particular loop. As a test, a source may be replaced by a storage battery; if the positive mesh current discharges that battery, the voltage of the source is positive; if the battery is charged, the source is negative.

Consider now the matrix shown in figure 2, with the "branch" letters written to the left, and the "mesh" letters on top. The first row is to be interpreted as $a = -x + v$, that is, the current in conductor $a$ is equal to that in mesh $v$ less the current in mesh $x$; this agrees with the sketch of the network.

The other horizontal rows have a similar meaning for the other branches of the network, as may be readily verified. The matrix thus represents the relationship between the branch currents and the mesh currents. The number of rows is equal to that of the branches, and the number of columns to that of independent loops or meshes. The idea behind this representation is to refer Kirchhoff's first law to the same meshes for which the second law is written, and thus to have all the relations among the currents and among the voltages represented by the same matrix.

Now read the last column of the dyadic from the top down, assuming the letters to

$C =$

| | x | y | z | t | u | v |
|---|---|---|---|---|---|---|
| a | -1 | | | | | 1 |
| b | | -1 | | | | 1 |
| c | | | -1 | | | 1 |
| d | | | | -1 | | 1 |
| e | | | | | -1 | 1 |
| f | 1 | -1 | | | | |
| g | | 1 | -1 | | | |
| h | | | 1 | -1 | | |
| i | | | | 1 | -1 | |
| j | -1 | | | | 1 | |
| k | 1 | | | | | |
| l | | 1 | | | | |
| m | | | 1 | | | |
| n | | | | 1 | | |
| p | | | | | 1 | |

Fig. 2.

refer to the voltages, and not to the currents. This column reads $v = a + b + c + d + e$, in other words, it states that the total applied voltage around the mesh $v$ is equal to the sum of the applied voltages in the branches $a$, $b$, $c$, $d$, $e$. The other columns contain the corresponding relationships for the other meshes; a comparison with the network itself will show the signs of the voltages to be also correct. Thus, for the total current the dyadic is written using the current vector combinations $ax$, $ay$, etc., whereas for the voltage it is written with $xa$, $xb$, etc. The second dyadic is called transpose or conjugate with respect to the first. The underlying reason for which the same dyadic is correct for both the currents and the voltages is now seen to be that currents are added in parallel, whereas voltages are added in series. Consequently, following the mesh letters ($x$, $y$, $z$, etc.) horizontally by rows, one encounters the meshes between which a given conductor is situated. Following the branch letters vertically by columns ($a$, $b$, $c$, etc.) one follows the branches which combined form a given loop. In this manner, the representation by dyadics becomes firmly established on the basis of the fundamental electrical principles.

Let the impedance of the individual branches of the network be denoted by $Z$'s with the corresponding double subscripts, the subscript $nn$ meaning that the resistance, the self-inductance, and the capacitance of the $n$-th conductor or branch are meant. In a steady state, $Z$ is a function of the frequency. In a transient state, the operator $p = d/dt$ is included in it. The mutual magnetic inductance between the $n$-th and the $m$-th branch is denoted by $X_{mn}$. It is identically equal to $X_{nm}$, and for this reason the impedance matrix of a stationary passive network is always symmetrical. In the dyadic notation $Z$ stands for both $Z_{nn}$ and $X_{nm}$, so that the general expression for the voltage drop in the individual branches is

$$E + e = Z \cdot i \qquad (1)$$

where $E$ is the voltage between the terminals of the conductor and $e$ is the sum of the external voltages inserted in the branch. The term $Z \cdot i$ includes a summation over all the branches which posses a mutual inductance with the branch under consideration. When summing up equation 1 over a closed mesh, the sum of the $E$'s becomes zero, and we have the usual expression for Kirchhoff's second law.

In accordance with Kron's notation, let the vector of the fictitious currents circulating over the meshes be denoted by $i'$, and the vector of the sums of the external applied voltages over the meshes by $e'$. In other words, let $i' = i_x x + i_y y +$ etc. Then, since all the relations are linear, we may write the dyadic expression in the form

$$e' = Z' \cdot i' \qquad (2)$$

where $Z'$ for the present simply stands for a dyadic of coefficients of proportionality between the new currents and the voltages. The relationship between $e$ and $e'$ on the one hand and between $i$ and $i'$ on the other hand is determined by the matrix in figure 2; consequently, there must be a definite dyadic relationship between the actual branch impedance $Z$ and the new impedance $Z'$. The components of the latter may be called mesh impedances or equivalent impedances, since they do not refer to the real branch currents, but to the fictitious mesh currents. Knowing $Z'$ and $e'$, these latter currents may be computed, and then the real branch currents calculated from the rows of the matrix in figure 2. Thus, our next problem is to find the relationship between $Z$ and $Z'$.

Let the matrix in figure 2 be denoted by $C$. It is called a transformation matrix, because by means of it the variables are changed from the branch currents to the mesh currents. The physical circuit itself is not modified. Thus

$$i = C \cdot i' \qquad (3)$$

For the voltages, the transpose matrix, $C_t$, must be used, as is explained above, and we have

$$e' = C_t \cdot e \qquad (4)$$

This equation may also be written as

$$e' = C_t \cdot (E + e) \qquad (5)$$

because a summation of the $E$'s over a mesh gives zero. From equations 1, 2, 3, and 5, the relationship between $Z$ and $Z'$ may be determined as follows: Multiplying both sides of equation 1 by $C_t$ and substituting for the left-hand side its value from equation 2 we get:

$$Z' \cdot i' = C_t \cdot Z \cdot i$$

Using the value of $i$ from equation 3 and cancelling $i'$, we finally obtain

$$Z' = C_t \cdot Z \cdot C \qquad (6)$$

This is Kron's equation 19, and from here on the procedure is the same as in his articles, namely: First find $Z'$ as on page 232, and then compute $Y' = 1/Z'$. Multiply vector $e'$ by $Y'$. This will give the mesh currents $i' = Y' \cdot e'$. Finally determine $i$ from $i'$ by using the transformation matrix $C$.

In the foregoing deduction of equation 6, it has not been necessary to introduce the power output, $P = i \cdot e = i' \cdot e'$, as an invariant. In fact, this mode of approach permits to deduce that the power is an invariant. Branch currents are changed to the mesh currents, but physically everything remains the same. Another advantage is that the inverse of the dyadic $C_t$ is not used in the deduction of equation 6. The dyadic being singular in its very nature, its determinant is equal to zero; therefore, it is preferable not to use $C_t^{-1}$ at all.

Because the transformation formulas are not derived from an invariant form, the foregoing deduction is not an example of tensor analysis; one is not permitted to use lower and upper indices in that sense. It is of interest to investigate the possibilities of generalizing this method, for example, by opening the network at a few points and connecting another circuit to it.

**Joseph Slepian** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): The first basis of good mathematics is probably the careful definition of terms. We have learned to follow and even improve upon the model set by Euclid, and to desire that each new term introduced into a mathematical work will be given a careful, and precise definition. We hope that the definition will have content. That is, that it should be free from self contradiction, and actually apply to some object. We hope that the definition will be sufficient. That is, that it will state all the qualities or properties necessary to distinguish the defined object from other objects. We hope the definition will be permanent. That is, that the meaning of the newly defined term will stay the same throughout the mathematical work. Lastly, we hope that so far as possible, the definition will conform to previous usage. The more widespread that previous usage, the less will we approve of any radical departure from previously used meanings.

The papers of Kron and Boyajian, appear to me to err in all these respects. Their definitions of the new terms or concepts which they introduce, seem mutually contradictory, insufficient, impermanent, and differ from previous and generally accepted usage.

From the titles of the papers, we would expect at least that adequate definitions of the "tensor" would be given. Also since the tensor is generally believed to be a generalization of the "vector," and opinion

apparently concurred with by Boyajian, but dissented from by Kron, we would expect an adequate definition of the "vector."

Kron, in his paper, page 1221, 1st column, refers to *General Electric Review*, volume 38 April 1935, page 181–91, and May 1935, page 230–43, "in which all the necessary definitions are stated." Turning to these references, we find in the first, page 181, first column, "the theory of tensors (known also under the name of hypercomplex numbers, polyadics, matrices, etc.)." Apparently then, the as yet undefined terms "tensors," "hypercomplex numbers," polyadics," "matrices," "etc., "all stand for the same thing. Perhaps a little dismayed by the plethora of names, including the "etc." for the same thing, we nevertheless proceed on in the reference.

The next suggestion of a definition we find on page 182, second column, "...replaced by hypercomplex numbers, that is, by sets of numbers arranged in a row (vector) or a square (matrix), etc." Here the terms "vector" and "matrix" seem to be no longer equivalent to the term "hypercomplex numbers," as before, but now the "vector" and "matrix" seem to be special cases of "hypercomplex numbers." "Vector" seems to refer to the capability of a set of numbers of being arranged in a row. Since, however, any set of numbers can obviously be arranged in a row, at least if it is a finite set, we seem to be told that any finite set of numbers is a "vector." Likewise "matrix" seems to refer to the capability of a set of numbers of being arranged in a square. But since any $n^2$ numbers, where $n$ is an integer, can be arranged in a square, we seem to be told that any set of $n^2$ numbers is a "matrix." These $n^2$ numbers, if we like can also be arranged in a row, so apparently a "matrix" is also a "vector."

Proceeding further in the reference, we find after $3^1/_2$ full pages of text, the first explicit definition, page 184, column 2, "An expression such as $(e_a a + e_b b + e_c c)$ ...is called a vector." Apparently, now, to be a "vector," the set of numbers must not only be placed in a row, but must be written with symbols, $a$, $b$, $c$, following each number, and with plus signs between successive numbers. But since obviously, any finite set of numbers can be set down in this way, if the writer chooses, again we seem to be told that any finite set of numbers is a "vector."

Boyajian is even more outspoken in enunciating this view, although there is some suggestion of uneasiness about a necessary relationship of the set of numbers to reference axes. Thus (ELECTRICAL ENGINEERING, August 1936, page 857, column 2), "Stated broadly, a vector is a quantity resolvable into a set of independent components." Again (ELECTRICAL ENGINEERING, August 1936, page 858, columns 1 and 2), "to constitute a generalized vector, the set of quantities $e_1 e_2 \ldots e_n$ need not represent a physically directed quantity in space, nor a harmonic quantity in time; in fact, it is not necessary to know what physical quantity they represent, in order to decide whether or not they constitute a generalized vector. They may be considered, at least tentatively, as constituting a generalized vector...if they ...constitute one group of related but independent quantities."

Since the members of any set of numbers are related, by being parts of one set, and independent, by being distinct from one another, Boyajian apparently also believes that any finite set of numbers is, "at least tentatively," a vector.

Thus according to these views, we have so bizarre a "vector" as today's closing quotations of the New York Stock Exchange. These are certainly a group of related quantities; in fact they are printed on the same newspaper page because of their common quality. That they vary independently, any speculator can testify. Although in the newspaper, they are usually arranged in columns, they could be arranged in a row. Actually on the ticker tape they are so arranged, and each number has set beside it a symbol, as *GM* $68^1/_2$...*GE* $59^1/_8$ ...*UP* 128, which, except for the absence of plus signs, is very reminiscent of Kron's $e_a a + e_b b + e_c c$. Apparently according to the definitions of Kron and Boyajian, the stock market quotations are "at least tentatively" a vector.

But these definitions are entirely different from the generally accepted meanings given to vectors. Let us limit outselves to vectors in ordinary Euclidean space. All the usual treatments of vectors in Euclidean space begin by assigning to vectors the notions of length or magnitude, and direction. These seem to be the primary defining properties of vectors which practically all text books agree upon. "Components" then come in only as the appropriate mathematical means for describing magnitude and direction.

In these days of relativity, we are all aware that length and direction have no absolute significance. We cannot describe the direction of a vector except with reference to other objects having direction, nor can we specify its length except with reference to some other object having length. Thus the "components" of a vector which mathematicians introduce to properly describe its length and direction are not absolute, but are relative to some system of reference object which themselves have length and direction. The "components" of a vector are relative to a reference system of vectors.

A vector, then, has not one set of components, but infinitely many sets, one for every vector reference system that may be chosen. Furthermore, all these various sets of components must be mutually related so that each in its own reference system indicates the same "directed magnitude." The so-called transformation equations which the sets of components must satisfy are merely the expression of the property of the vector of having length and direction.

A displacement in space which is the typical vector, has length and direction, and therefore has infinitely many mutually related sets of components referred to the various possible reference displacement systems, but the report of stock market quotations, which has only one set of components, has neither length nor direction and is not a vector according to usual notions.

Evidently the definitions of Kron and Boyajian which make an arbitrary set of numbers, such as a stock market report, a vector, "at least tentatively," must differ very radically from the generally accepted meaning given to "vector."

If we pursue further the reference given by Kron, we go through over 15 pages of text with the word tensor used scores of times. Although they are as yet undefined, "tensors," "dyadics," "polyadics," "matrices," "hypercomplex numbers," and "etc.," seem to be used indiscriminately synonomously. But, at last, page 234, we come to section VII, "Definition of a Tensor." We learn, "those polyadics whose formulas of transformation are the simple ones given in equations 37 are called 'tensors,'...the word tensor is limited to a definite class of polyadics..." Apparently the preceding use of the words "tensor" and "polyadic" as synonymous in Kron's work was a mistake.

Boyajian seems to be able to use the word "tensor" without requiring "polyadics." But his test for the tensor quality of his "transformation tensor" on page 862, seems to involve only such manipulation of indices as Kron performs upon all his "polyadics," which Kron states are not always "tensors." May I ask Boyajian whether his test may not merely demonstrate the "Kronian polyadic?" quality of his "transformation tensor" and perhaps not its tensor quality.

Going a little further in Kron's reference, page 234, column 2, "Whether a vector or a dyadic, etc., is a tensor or not, does not depend...." Apparently according to Kron a vector need not always be a tensor. However, every book, which I have consulted makes the vector a special case of a tensor, that is, a tensor of rank one. Boyajian also in his paper, says, page 857, column 2, "vectors come in as a special class of tensors" and page 860, column 1, "the common vector is merely a special case as a one-dimensional tensor, or a tensor of rank one." Can Kron justify his usage of the word vector which seems to differ from that of all others?

On page 235, column 2, of his reference, Kron becomes even more specific. He now says that a vector has "length," or magnitude, and "If the magnitude of a vector is the same irrespective of the co-ordinate system...it is called a tensor."

But Kron gives no definition of the "length" or "magnitude" of a vector. Would he find the "length" of the vector current such as he uses in his present paper by taking the scalar product of it with itself, meaning thereby the sum of the squares of its components? If so, then he would violate his rules for manipulating indices. But how otherwise? A similar question might be addressed to Boyajian who, on page 858, column 2, gives examples of a purportedly purely contravariant vector, and a purportedly purely covariant vector, each having length or magnitude. However, whatever the resolution of this dilemma may be, Boyajian, contrary to Kron, seems willing to let the lengths or magnitudes of his vectors vary with transformation of co-ordinates, without their losing their tensor character.

We might also ask Kron whether his criterion for the tensor character of a vector last quoted is consistent with the previously quoted "Definition of a Tensor" as those "polyadics" which satisfy the "equations" 37. If the components of a vector satisfy the "equations" 37 will its

"length" necessarily be unchanged by the transformation and vice versa?

One more question of definition. On page 239, column 1, of Kron's reference, we find "A tensor whose elements are complex numbers is called a spinor." Since "spinors" are used now quite widely in the literature of quantum-mechanics, and not at all in the sense of the quoted definition, will Kron give one reference to justify his definition?

I have already intimated that I believe Boyajian's treatment of covariance and contravariance to be unsound. If the space under consideration is metrical, as seems to be the case since Boyajian refers to the "magnitude" of his vectors, then any vector has both covariant and contravariant components as Sah brings out in his second paper in the section "Covariant and Contravariant Measure Numbers."

Refer to the equation in Kron's paper, page 1231, bottom of second column. This gives a relation between the components of the variables $\Delta X$ in the "old reference system" $\Delta X^m$ and the "new," $\Delta X^\alpha$. Is it not then the "transformation equation" and therefore does it not define the "transformation tensor?" But on page 1224, second column, we find "In this presentation all transformation tensors have only constant components..." In other words, is there not a contradiction with equations 38?

In Kron's paper page 1233, first column, the complex number

$$\Delta\hat{e}_1 = \Delta e_1 + j\Delta e_1'$$

is set down equal to a real number. Is this not a contradiction? The title of this section is called complex Taylor's series. But "Taylor's series" usually means the expansion of a function of a variable into a power series, such as equation 61 where the coefficient in each term is $1/n!$ times the value of the $n$th derivative of the function taken at some definite point. I fail to find any such expanison in this section. How does Kron justify the title, "Taylor's Series?"

In this section, where the applied voltage $\Delta e$ is supposed to be resolvable into $n$ components with different frequencies, it is said that there will in general be $n+2n^2$ components of current, (if, as I presume, higher powers than the second of the component $\Delta e$'s are neglected). Apparently the only distinguishing or defining feature of these components is their frequency. But, even in the most general case there will not by as many as $n + 2n^2$ different frequencies. For obviously in the square array of component currents shown in the second column of page 1233, the frequency $w_1 + w_2$ is equal to the frequency $w_2 + w_1$, etc. Hence in this square array there will in general be only $\frac{1}{2}n(n + 1)$ distinct frequencies. Does Kron intend the component $\Delta i^{w_2 + w_1}$ to be different from $\Delta i^{w_1 + w_2}$? If so, will he not need a different notation? Or is $w_1 + w_2$ not equal to $w_2 + w_1$? Will the total current $\Delta i$ always contain the two terms $\Delta i^{w_1 + w_2} + \Delta i^{w_2 + w_1}$ always summed together? If so, why not use only a single letter for this sum, since the component terms can never be determined by any test, and may therefore perhaps be said not to exist individually.

Similar remarks may be applied to the matrix for $\Delta i^{(\alpha)(-\beta)}$. The frequency $w_1 - w_2$ is the negative of the frequency $w_2 - w_1$. Does Kron permit the frequency to be negative? If so, how do these negative frequencies make their presence apparent? If not, then $\frac{1}{2}n(n-1)$ of the $n^2$ frequencies referred to in $\Delta i^{(\alpha)(-\beta)}$ disappear. Also in the matrix for $\Delta i^{(\alpha)(-\beta)}$ the frequencies for the diagonal terms are all alike and zero. Apparently even in the most general case there are for these $n + 2n^2$ components of current only $n^2 + n + 1$ distinct frequencies But if the $n + 2n^2$ components of current dealt with in this section are not defined by their individual frequencies, how are they defined?

In the next section, page 1234, entitled "Compound Series," Kron assumes that for any given total impressed voltage it is somehow possible to separate and distinguish components of "fundamental frequency" from components of "product frequency." But such a resolution is not at all unique. For example, suppose we have actually impressed upon a system a voltage having components of 10, 15, 25, and 35 cycles, and let us say each of these components has the value one. Then if we like, we may regard these all as "fundamental frequencies," and in Kron's equation 85 set $\Delta e_{(\sigma)}$, and $\Delta e_{(\gamma)}$ $\Delta e_{(\delta)}$, each as unity, and the $\Delta e_{(\gamma)}$ $(=\delta)$ each as zero. But we may, if we like, take only the 10 and 25 cycles as fundamental, and regard the 15 and 35 cycles as product frequencies. Then in Kron's equation 55, $\Delta e_{(\sigma)}$ stands for $\Delta e_{10}$ and $\Delta e_{25}$, each to be taken as one; $\Delta e_{(\gamma)}$, $\Delta e_{(\delta)}$ also stand for $\Delta e_{10}$ and $\Delta e_{25}$ and each to be taken as one. But $\Delta e_{(\gamma)}$ $(=\delta)$ now stand for $\Delta e_{25} = 10$, that is for $\Delta e_{15}$ and $\Delta e_{35}$ and are now to be taken as unity. Similarly we may take 10, 15, and 25 cycles as fundamental and regard only the 35 cycles as product frequency. Since each of these equally plausible ways of regarding the applied voltage, when applied to the equation 85 would seem to give different results, some doubt may be cast upon the correctness of the treatment.

At the end of this section, page 1234, column 1, it states that "all symbols,—such as $Z_{(\epsilon)(\sigma)}$ are not "polyadics" (as defined in reference 1*Da*)...." This contradicts the statement quoted earlier that "all the necessary definitions are stated" in reference 1*A*. It is most disconcerting, after receiving the impression in Kron's reference, from April 1935 to Jan. 1936, that "polyadics" and "hypercomplex numbers" are synonymous, to at last receive a definition in February 1936, which makes them different.

The section called "Inverse of the Complex Series," on page 1236, seems to deal with what were called "Compound Series" on page 1234.

Here, again, the lack of definition enabling one to distinguish between $\Delta i^{w_1+w_2}$ and $\Delta i^{w_2+w_1}$, and the ambiguity as to what are to be called "fundamental frequency" and what "product frequency" make the value of the work seem quite doubtful.

**A. P. T. Sah** (National Tsing Hua University, Peiping, China): The gateway to Kron's work hinges on his "connection tensor" $C$. It is unfortunate that Kron has not explained this fundamental quantity clearly in his writings, since 2 easily recognized inconsistencies in the exposition of the "connection tensor" $C$ have appeared in his papers. In the first place the "connection tensor," by its very nature, is necessarily singular and cannot have a reciprocal. And yet the reciprocal of $C$ or of its transpose has been not only written down in explicit equations (See equation 37, *General Electric Review*, volume 38, page 234, May 1935 and equation 38, ELECTRICAL ENGINEERING, page 1226, November 1936) but also used in making demonstrations. The second inconsistency has to do with Kron's "generalized network" (See figure 4, ELECTRICAL ENGINEERING, page 1228, November 1936). In figure 4*a*, the so-called "generalized network" is shown with all coils short-circuited through applied electromotive forces. From such a diagram one would necessarily conclude that the currents in the coils are uniquely determined when all the electromotive forces and the impedances are known. But these current values cannot satisfy the constraining conditions as shown in figure 4*b* for the same applied electromotive forces and the impedances of figure 4*a*. It is believed that Kron's generalized network is entirely uncalled for since it represents neither a mathematical fiction nor a physical reality. In fact, it is in plain contradiction with the physics of the problem

Leaving aside the question of the *engineering* utility of the "connection tensor" in setting up circuit equations in any case, which, as correctly pointed out by Bewley (ELECTRICAL ENGINEERING, page 1215 November 1936), is neither simpler nor shorter than the old-fashioned Kirchoff's laws, it is hoped that Kron will revise his statements and demonstrations so as to make his "connection tensor" a flawless tool.

**A. W. Tucker** (nonmember; Princeton University, Princeton, N. J.): Professor Struik has pointed out that my recent work on tensor algebra in topology has a bearing on the applications of tensors to electrical engineering. To illustrate let us consider a network consisting of (directed) lines numbered 1, 2, 3, etc. and terminals I, II, III, etc.; an example, with figure, is given below. The combinatorial structure of such a network is exhibited by the array of *incidence numbers*.

$$N_a^\alpha = \begin{cases} 1 & \text{if the line } a \text{ ends at the terminal } \alpha \\ -1 & \text{if the line } a \text{ begins at the terminal } \alpha \\ 0 & \text{otherwise.} \end{cases}$$

In each line $a$ let there be a current component $e^a$ and at each terminal $\alpha$ a component $h_\alpha$ of potential. Then, using the summation convention,

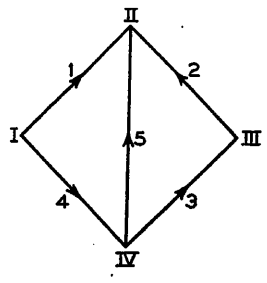
$$f^\alpha = N_a^\alpha e^a \tag{1}$$

$$i_a = h_\alpha N_a^\alpha \tag{2}$$

$$p = i_a e^a = h_\alpha N_a^\alpha e^a = h_\alpha f^\alpha \tag{3}$$

measure (1) the current flowing out of the network at the terminal $\alpha$ (say, into an external lead), (2) the voltage in the line $a$, and (3) the power in the network. If we now consider the same network in terms of

new elements 1′, 2′, 3′, etc. and I′, II′, III′, etc. formed from the old by a reversible process, we get new incidence numbers



$$N_{a'}{}^{\alpha'} = C_{\alpha}{}^{\alpha'} N_a{}^{\alpha} C_{a'}{}^{a}$$

and new components of current, potential, voltage, etc.,

$$e^{a'} = C_a{}^{a'} e^a, \; h_{\alpha'} = h_\alpha C_{\alpha'}{}^{\alpha}, \; i_{a'} = h_{\alpha'} N_{a'}{}^{\alpha'} = h_\alpha N_a{}^{\alpha} C_{a'}{}^{a}, \text{ etc.},$$

where $C_{a'}{}^{a}$, $C_a{}^{a'}$ are inverse transformations (i.e. $C_{a'}{}^{a}\, C_b{}^{a'} = 1$ if $a = b$ and 0 otherwise) as are $C_{\alpha'}{}^{\alpha}$, $C_{\alpha}{}^{\alpha'}$.

In topological parlance a network of lines and terminals is a *graph* of *edges* and *vertices* or a *1-complex* (i.e. one-dimensional complex) of 1-cells and 0-cells. Numbers $e^a$ attached to the 1-cells give a *1-chain*. The numbers $f^\alpha = N_a{}^{\alpha} e^a$ attached to the 0-cells give a special 0-chain called the *boundary* of the preceding 1-chain. Notice that Kirchhoff's law asserts that the boundary of a current vanishes—except at terminals with external connections. Numbers $h_\alpha$ attached to the 0-cells give a "dual" 0-chain—here the terminology is not well established for the notion is new. The "dual" boundary of this is the dual 1-chain given by the numbers $i_a = h_\alpha N_a{}^{\alpha}$ attached to the 1-cells. Instead of basing our chains on cells we may base them on suitable combinations of cells (i.e. chains). Thus we are led to consider *changes of basis*. The particular changes chosen in the above example serve to reduce the table of incidence to an especially simple form. The components of a chain such as current change contravariantly and those of a dual chain such as voltage change covariantly; hence their scalar product, or *intersection index*, is invariant under change of basis.

I hope these remarks indicate how topology enters as an intermediary in the application of tensors to electrical engineering. There is nothing new in the separate items of the above discussion; the only novelty lies in putting them together. The topology involved seems quite essential although being one-dimensional it is rather trivial from the geometrical point of view. However it is far from ruled out that higher dimensions may not come into the development as it unfolds.

C. E. Rose (Federal Emergency Administration, Washington, D. C.): Vector and tensor symbols will be written in capital type and since a vector is in reality a tensor of rank zero no ambiguity will result, because in this convention a vector will be defined as such by being without a sub- or superscript, whereas a tensor will always be written with its definitive subscripts and / or superscripts. Given any 2 arbitrary vectors $A$ and $B$, existing within orthogonal or affine space, we write their product as $AB$. This is neither their scalar product $A \cdot B$, not their vector product $A \times B$, and it is therefore at this point undetermined.

Write:

$$A = a_1 i + a_2 j + a_3 k, \tag{1}$$

$$B = b_1 i + b_2 j + b_3 k \tag{2}$$

in which $i$, $j$, and $k$ are the unit vectors and $a_1$, $a_2$, $a_3$ and $b_1$, $b_2$, $b_3$ are the respective projections of $A$ and $B$ upon the axes measured by these respective unit vectors.

We know from elementary vector analysis that:

$$i \cdot i = j \cdot j = k \cdot k = 1 \tag{3}$$

$$i \cdot j = j \cdot k = k \cdot i = 0 \tag{4}$$

as the scalar products of these unit vectors.

We also know that:

$$i \times i = j \times j = k \times k = 0 \tag{5}$$

$$i \times j = -j \times i = k \tag{6}$$

$$j \times k = -k \times j = i \tag{7}$$

$$k \times i = -i \times k = j \tag{8}$$

as the vector products of these unit vectors.

We, therefore, now write the product of equations 1 and 2 as:

$$\begin{aligned} AB = {} & a_1 b_1 ii + a_1 b_2 ij + a_1 b_3 ik + \\ & a_2 b_1 ji + a_2 b_2 jj + a_2 b_3 jk + \\ & a_3 b_1 ki + a_3 b_2 kj + a_3 b_3 ik \end{aligned} \tag{9}$$

We may now, as usual, substitute $a_{11}, a_{12} \ldots\ldots a_{33}$ for the coefficients of $a_1 b_1, \; a_1 b_2 \ldots \ldots a_3 b_3$ above, and write the scalar product of $AB$ as, the matrix:

$$A \cdot B = \begin{Vmatrix} a_{11} a_1 b_1 & 0 & 0 \\ 0 & a_{22} a_2 b_2 & 0 \\ 0 & 0 & a_{33} a_3 b_3 \end{Vmatrix} \tag{10}$$

and the vector product of $AB$ as, the matrix:

$$A \times B = \begin{Vmatrix} 0 & a_{12} a_1 b_2 & -a_{13} a_1 b_3 \\ -a_{21} a_2 b_1 & 0 & a_{23} a_2 b_3 \\ a_{31} a_3 b_1 & -a_{32} a_3 b_2 & 0 \end{Vmatrix} \tag{11}$$

add equations 10 and 11, yields:

$$AB = (A \cdot B) + (A \times B) = \begin{Vmatrix} a_{11} a_1 b_1 & a_{12} a_1 b_2 & a_{13} a_1 b_3 \\ a_{21} a_2 b_1 & a_{22} a_2 b_2 & a_{23} a_2 b_3 \\ a_{31} a_3 b_1 & a_{32} a_3 b_2 & a_{33} a_3 b_3 \end{Vmatrix} \tag{12}$$

We may further condense equation 12 and write:

$$AB = \sum_{ik} a_{ik} a_i b k = \begin{Vmatrix} a_{11} a_1 b_1 + a_{12} a_1 b_2 + a_{13} a_1 b_3 + \\ a_{21} a_2 b_1 + a_{22} a_2 b_2 + a_{23} a_2 b_3 + \\ a_{31} a_3 b_1 + a_{32} a_3 b_2 + a_{33} a_3 b_3 \end{Vmatrix} \tag{13}$$

If the right hand member of equation 13 remains invariant in form when subjected to any rotation about its co-ordinates, then we may write in tensor notation:

$$T_{ik} = \sum_{ik} a_{ik} a_i b_k \tag{14}$$

and equation 14 defines a covariant tensor of rank 2.

To test whether equation 14 is invariant let us rewrite equation 9 as before and rotate it 90 degrees around the $i$-axis. To do so write:

$$AB = \begin{Vmatrix} a_1 b_1 ii + a_1 b_2 ij + a_1 b_3 ik + \\ a_2 b_1 ji + a_2 b_2 jj + a_2 b_3 jk + \\ a_3 b_1 ki + a_3 b_2 kj + a_3 b_3 kk \end{Vmatrix} \tag{9}$$

and to apply to it the versor:

$$\phi = ii \cos e (jj + kk) + \sin e \, (kj - jk) \tag{15}$$

Since the original unit vectors in equation 9 are $i$, $j$ and $k$, then by multiplication of equation 9 by equation 15 we have rotated equation 9 90 degrees around the $i$-axis and

$$\begin{aligned} i' &= i \\ j' &= j \cos e + k \sin e, \\ k' &= -j \sin e + k \cos e \end{aligned} \tag{16}$$

$e$, the angular rotation in this cases being 90 degrees, equation 16 reduces to

$$\begin{aligned} i' &= i \\ j' &= k \\ k' &= -j \end{aligned} \quad \text{or} \quad \begin{aligned} i &= i' \\ j &= -k' \\ k &= j' \end{aligned} \tag{17}$$

Substitution of the values of $i$, $j$ and $k$, in terms of $i'$, $j'$, and $k'$ from equation 17 into equation 9 yields:

$$AB = \left\| \begin{matrix} a_1b_1i'i' - a_1b_2i'k' + a_1b_3i'j' - \\ a_2b_1k'i' + a_2b_2k'k' - a_2b_3k_1j' + \\ a_3b_1j'i' - a_3b_2j'k' + a_3b_3j'j' \end{matrix} \right\| \quad (18)$$

which is identical in form to equation 9. We may designate the coefficients as usual of the components $a_1b_1 \ldots a_3$, by $a_{11} \ldots a_{33}$ without losing any generality and the result is again equation 13, which proves that equation 9 and its developments, equations 12, 13, and 14, define a tensor, because its form is identical after this rotation of 90 degrees.

A contravariant tensor represents the "Path"; a covariant tensor represents the force along the "Path"; the first is defined by superscripts, the second by subscripts and the mixed tensor by both, as $A^{ik}$, $A_{ik}$, and $A_i^k$ respectively.

# Induction Motors on Unbalanced Voltages

**Discussion and authors' closure of a paper by H. R. Reed and R. J. W. Koopman published in the November 1936 issue, pages 1206–13, and presented for oral discussion at the induction machinery session of the winter convention, New York, N. Y., January 27, 1937.**

**H. J. Reeves** (Paul and Reeves, Spokane, Wash.): The authors treatment of the 3-phase motor on single-phase voltage might be presented in a slightly different manner. Sketch *B* of their paper could be

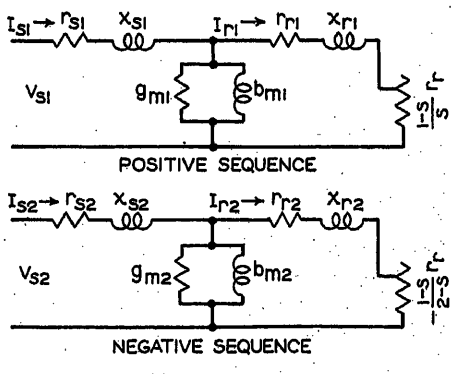

**Fig. 1**

changed to show the separate sequence circuits as in figure 1 of this discussion.

For the negative sequence circuit, the slip, $S_2$, is equal to 2 minus the positive sequence slip $S_1$. Thus,

$$\frac{1 - S_2}{S_2} = \frac{1 - 2 + S_1}{2 - S_1}$$

$$= -\frac{1 - S}{2 - S}$$

where $S_1$ is made equal to $S$ for the sake of brevity.

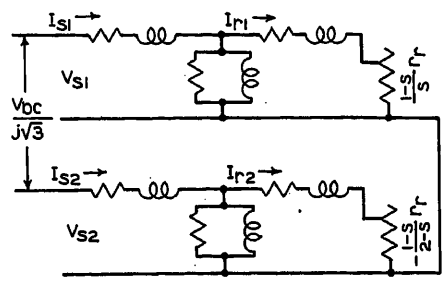

**Fig. 2**

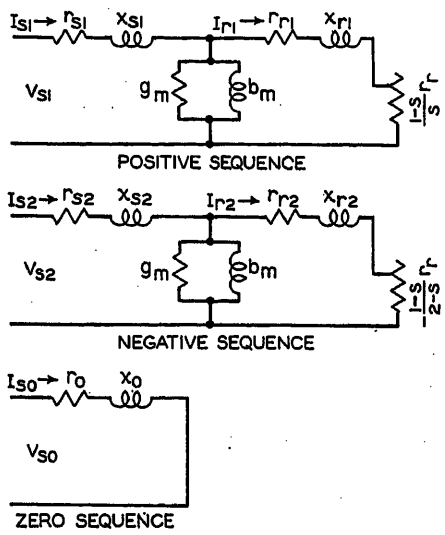

**Fig. 3**

For the 3-phase motor operating single phase we may assume $a$ phase open. The following relations will hold:

$$I_a = 0$$
$$I_b = I$$
$$I_c = I$$
$$I_{s1} = {}^1/_3 (0 + \alpha I - \alpha^2 I) = \frac{\alpha - \alpha^2}{3} I = \frac{j}{\sqrt{3}} I$$
$$I_{s2} = {}^1/_3 (0 + \alpha^2 I - \alpha I) = \frac{\alpha^2 - \alpha}{3} I = -I_{s1}$$

$$V_b = \alpha^2 V_{s1} + \alpha V_{s2}$$
$$V_c = \alpha V_{s1} + \alpha^2 V_{s2}$$
$$V_{bc} = V_c - V_b = (\alpha - \alpha^2) V_{s1} + (\alpha^2 - \alpha) V_{s2} = (\alpha - \alpha^2)(V_{s1} - V_{s2}) = j(\sqrt{3} V_{s1} - V_{s2})$$

$$I_{s1} = I_{s2} \quad (1)$$

$$\frac{V_{bc}}{j\sqrt{3}} = V_{s1} - V_{s2} \quad (2)$$

For analytical purposes, connect the sequence networks together as in figure 2 to satisfy the conditions of equations 1 and 2. This solution will permit the use of the familiar tabulation in columnar form for the calculation of motor performance curves. To the table for balanced 3-phase voltage operation will be added the negative-sequence calculations for the corresponding values of slip, and the changes in positive-sequence values resulting from the changes in positive-sequence voltage.

The practical limits of $\frac{1 - S}{S} r_r$ are zero and infinity, and of $-\frac{1 - S}{2 - S} r_r$ are zero and $-0.5 r_r$. It will be noted that in the working range, $-\frac{1 - S}{2 - S}$ may be assumed to be $-0.5$ without appreciable error. Since the values of negative-sequence voltage near synchronous speed are low we may assume

$$I_{r2} = I_{s1}$$

and the negative sequence torque will then be

$$T_2 = -0.176 \frac{P r_r}{f(2 - S)} I_{s1}^2$$

The loss in speed necessary for a balance between negative and positive sequence torques is slight and is usually less than one per cent.

Another interesting application can be made to the Y-connected motor operating on a 4-wire 3-phase circuit, with one of the phase wires open. A motor operating under this condition will have considerable starting torque, since a positive angular displacement between the 2-phase windings is maintained. The following solution for this condition might be used.

$$I_a = 0 = I_1 + I_2 + I_0 \quad (3)$$

$$I_b + I_c + I_N = 0$$

$$V_b = \alpha^2 V_1 + \alpha V_2 + V_0 \quad (4)$$
$$= \alpha^2 I_1 Z_1 + \alpha I_2 V_2 - (I_1 + I_2) Z_0$$
$$= I_1 (\alpha^2 Z_1 - Z_0) + I_2 (\alpha Z_2 - Z_0)$$

$$I_2 = \frac{V_b - I_1 (\alpha^2 Z_1 - Z_0)}{\alpha Z_2 - Z_0} \quad (6)$$

$$V_c = \alpha V_1 + \alpha^2 V_2 + V_0$$
$$= \alpha I_1 Z_1 + \alpha^2 I_2 Z_2 - (I_1 + I_2) Z_0$$
$$= I_1 (\alpha Z_1 - Z_0) + I_2 (\alpha^2 Z^2 - Z_0) \quad (5)$$

$$= I_1 (\alpha Z_1 - Z_0) + \frac{V_b - I_1(\alpha^2 Z_1 - Z_0)}{\alpha Z_2 - Z_0} \times (\alpha^2 Z_2 - Z_0)$$

$$I_1 = \frac{V_c(\alpha Z_2 - Z_0) - V_b(\alpha^2 Z_2 - Z_0)}{(\alpha Z_1 - Z_0)(\alpha Z_2 - Z_0) - (\alpha^2 Z_1 - Z_0)} \times (\alpha^2 Z_2 - Z_0) \quad (7)$$

The sequence networks are shown in figure 3. These should be connected together to satisfy the conditions of equations 3, 4, and 5, but as this condition does not lend itself readily for simple solution, $I_1$ may be calculated from equation 7 and $I_2$ from 6.

For this solution the values for 3-phase balanced operation may be utilized and the values for the negative-sequence circuit may be taken from the additions which have been noted above.

The starting torque and current values of table I and the speed-torque characteristics of figure 4 have been calculated from the following constants of a 5-horsepower, 220-volt, 3-phase, 60-cycle, 6-pole motor, all being expressed in unit values.

| | | | |
|---|---|---|---|

*A*—Motor operating on balanced 3-phase voltage
*B*—Motor operating single-phase line-to-line voltage
*C*—Motor operating on 2 phases of the 3 line-to-neutral voltages

**Selby Haar** (Board of Transportation, City of New York, N. Y.): Tests of a number of 3-phase squirrel cage rotor motors of 1 to 2½ horsepower, presumably with balanced windings, on a circuit with approximately 1 per cent unbalance of voltages showed unbalanced currents as high as 20 per cent. If the motors are provided with controllers of standard type with overloads in 2 lines only, an overload setting sufficient to carry the larger current may be too high to protect the other phase windings of the motor. Hence unbalanced voltages in a polyphase supply system may be a serious matter.

**G. F. Corcoran** (The State University of Iowa, Iowa City.): The authors have combined symmetrical-component circuit theory with classical polyphase-induction-motor theory to advantage. By strict adherence to accepted principles in these 2 fields they have simplified the general problem of predetermination of induction-motor characteristics under unbalanced voltage conditions.

An important feature of the method presented in this paper is the absence of empirical constants and other data that can be obtained only by elaborate tests. No parameters other than those which can easily be calculated from ordinary test data or from ordinary design data have been employed in the calculations. It is obvious that $g_e$, $b_e$, and $r_q$ are not exactly the same for the 2 equivalent circuits, namely, the positive-sequence circuit and the negative-sequence circuit. With the aid of empirical data and various assumptions several refinements in $g_e$, $b_e$, and $r_q$ might be affected. However, the amount of additional labor involved and the inaccuracies encountered in obtaining actual magnetizing reactances discourage any general attempt in this connection.

For a particular operating condition, certain refinements are entirely feasible. For example, at low values of slip $s_1$ the negative-sequence voltage is low and $g_e$ in the negative-sequence circuit could be adjusted accordingly with due regard for the saturation effects caused by the positive-sequence flux. It will be observed, however, that quite uniform results have been obtained neglecting "saturation effects" entirely. Also at low values of $s_1$ the approximate double-frequency rotor current in the negative-sequence circuit will make for higher rotor resistance and simultaneously there will be a high-frequency core loss. Both of these effects could, conceivably, be taken into account in the present method by increasing $r_q$ in the negative-sequence circuit by the appropriate amount for each different value of slip. Refinements of this nature are, of course, incidental to the general theory involved because accurate results necessarily involve the use of accurate circuit parameters.

The remarkable feature of the present method is that the experimentally determined results agree as well as they do with those calculated on the basis of constant $g_e$, $b_e$, and $r_q$. As shown in the paper, the calculated values agree with the experimentally determined values better for low values of $s_1$ than for higher values of $s_1$. Certain irregularities due to inherent space harmonic effects are to be expected for particular low values of $s_1$.

The theory underlying the introduction of a negative resistance

$$r_q \frac{(1 - s_2)}{s_2}$$

where $s_2 > 1$

is of some importance because the electromagnetic power developed by the negative-sequence field is:

$$-\left[I_q^2 r_q \frac{(1 - s_2)}{s_2}\right] \qquad (1)$$

In this connection it is interesting to note that power crossing the gap via the negative-sequence field is:

$$\left[I_q^2 \frac{r_q}{s_2}\right] \qquad (2)$$

Physically, of course, there are $I_q^2 r_q$ watts dissipated in heat in the $q$ branch of the negative-sequence circuit and this is supplied only partially by the power that crosses the gap via the negative-sequence field.

$$I_q^2 r_q = I_q^2 \frac{r_q}{s_2} - I_q^2 r_q \frac{(1 - s_2)}{s_2} \qquad (3)$$

The voltage relations involved in the negative-sequence circuit when $s_2 > 1$ are shown in the accompanying sketch. A comparison of these relations with the well-known positive-sequence circuit relations when $s_1 < 1$ will further disclose the reason for the introduction of negative resistance into the negative-sequence equivalent circuit.

Although the present method as applied

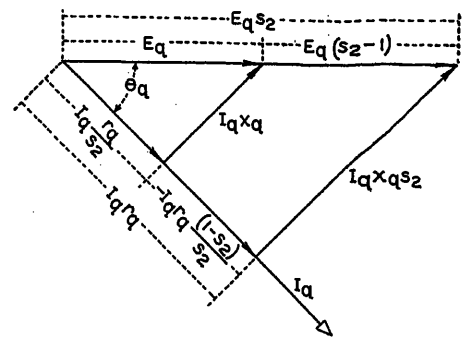

**Fig. 4. Voltage and current relations in the rotor of the negative-sequence circuit**

From a rotor point of view

$$I_q = \frac{E_q s_2}{r_q^2 - x_q^2 s_2^2}$$

From a stator point of view

$$I_q = \frac{E_q}{(r_q^2/s_2^2) - x_q^2}$$

to the single-phase case possesses certain features which are contained in the common 2-network single-phase equivalent circuit, it is definitely superior in several respects. The voltage to employ in connection with each circuit can be calculated in a straightforward manner. This particular feature is distinctly advantageous in the single-phase case and it is thought that the present method of attack will find its greatest field of usefulness in single-phase motor analysis.

**F. H. Pumphrey** (Rutgers University, New Brunswick, N. J.): I have been interested in the presentation of this paper primarily as a teacher of the subject of electrical machinery. The schools have faced tremendous pressure to reduce the amount of time spent in the study of electrical machinery. One of the ways that this has been accomplished is by obtaining a closer coordination of the theory of machines. With this in view, several years ago, I discarded the cross-field theory of single-phase induction motor operation, and adopted the symmetrical-component analysis as presented in this paper. It has had several advantages. First, it has given an excellent illustration of the use of symmetrical components, second, it has permitted me to use all of the polyphase motor theory that had been built up and thus save time, and third, it has given, I believe, a better physical understanding of the phenomena. I should welcome comments from designing engineers as to the relative merits of the symmetrical-component attack versus the cross-field theory where time permits the presentation of but one.

**P. H. Trickey** (Diehl Manufacturing Company, Elizabethport, N. J.): Is it possible to use this method when the turns and weights of wire in the two windings of a capacitor motor are not equal? (Note: (1) Kingsley of MIT replied to this question; (2) A professor from Rhode Island State asked what was being taught at

present, the revolving field or cross-field theory of single-phase motors; (3) Kingsley said that at MIT, they were teaching the revolving field theory exclusively; (4) Karapetoff, of Cornell, implied in a discussion that these methods of calculating capacitor motors were based on superposing 2 separately revolving fluxes, and that there was danger of inaccuracies due to saturation effects.)

1. The question as to whether the revolving field theory or cross-field theory should be used in single-phase motor analysis has been debated for many years. The engineers in our company are using both methods side by side in every day routine design problems, and I want to urge very seriously that neither method be allowed to drop out of the minds of men engaged in teaching.

For instance, the single-phase calculation method developed by C. G. Veinott and H. R. West, is based on the cross-field theory and is used by engineers of at least 4 large engineering companies. There are certain features that seem to be illustrated much more vividly than by the revolving field theory. On the other hand, such phenomena as the double-frequency rotor currents in a single-phase motor are not easily visualized by the cross-field method.

2. I think the authors of these papers on methods of calculating capacitor motors are to be commended, and I want to urge them as well as others, to keep working on this problem. There are now a number of different methods of attack, all of which can be used to calculate the performance. The principle difficulty now is the length of time involved. Those of us engaged in routine design need very badly a calculation method which is not appreciably longer than that which we use on single-phase motors. Our present method for polyphase motors involves 26 slide rule operations to calculate the performance for any given slip while the single-phase method takes 35 operations. The best I have been able to arrange any of the capacitor motor methods so far has been 107 operations. If we could cut this down to 40 or even 45, it would become very useful. This, of course, must be for capacitor motors where the two phases are not alike as we very seldom use equal windings.

3. I believe the inaccuracies due to saturation are not very serious due largely to the primary impedance dropping the induced voltage and the flux as the slip is increased. In any case, we need a method and it would be useful even with some error due to saturation.

**G. F. Tracy** (University of Wisconsin, Madison.): Reed and Koopman have used the expressions developed in their paper in order to predict the torque, currents, and voltages of a 3-phase motor operating as a capacitor motor at all slips from standstill to synchronous speed. From a practical standpoint the values of torque and line current at standstill are most significant, since these values determine the practicability of such a method for starting the motor. In a paper entitled "Split-Phase Starting of Three-Phase Motors," by Tracy and Wyss, in ELECTRICAL ENGINEERING, October 1935, page 1068, expressions for torque and current similar to those in Reed and Koopman's paper were developed for the case of split-phase starting using a noninductive resistance in series with one terminal of the motor, and an inductive reactance in series with the second terminal; the third terminal being connected directly to the other side of the line. The expression for torque was further analyzed by differentiation to find the "best" values of resistance and reactance in terms of the constants of the motor; i.e., that pair of values which will produce maximum starting torque (equation 22 in Tracy and Wyss' paper). A similar analysis of the companion case using a resistance and a capacitive reactance was subsequently carried out by J. W. Soule, graduate student at the University of Wisconsin. The best value of resistance was found to be zero in all cases (actually slightly negative); while the best value of reactance was shown to be given by the surprisingly simple and valuable expression $X_c = 1.5z$, where $X_c$ is the value of capacitive reactance in ohms and $z$ is the value in ohms of the equivalent impedance per phase of the motor at standstill, motor assumed Y-connected. The validity of the above expression was verified in a series of tests by Soule; and it is also interesting to observe that when applied to the $^3/_4$-horsepower motor in Reed and Koopman's paper this expression yields a value of capacitance of 245 microfarads, whereas figure 8 of the paper shows the maximum starting torque to occur at 240 microfarads. In the case of the 5 horsepower motor, Reed and Koopman do not show starting torque as a function of capacitance. The best value of capacitance according to the above expression is 690 microfarads; i.e., more than 4 times as large as that used in the curves of figures 5–7. Had the value of capacitance used in their tests been 690 microfarads instead of 160 microfarads the starting torque would have been 150 per cent of the 3-phase starting torque instead of approximately 13 per cent as in figure 5. The starting torque corresponding to the best value of $X_c$ is readily computed from $T = 28.8\, r/(z - x)$, where $T$ is in per cent of 3-phase starting torque, and $r$, $z$, and $x$ are respectively the numerical values of the resistance, impedance, and reactance, in ohms per phase of the motor at standstill, motor assumed Y-connected.

In general, the starting torque obtainable with an inductive reactance and a resistance connected as described above does not exceed 20 per cent of 3-phase starting torque even with the best values used for the resistance and reactance. It is a relatively inexpensive method, however, and is thus adaptable to large machines. On the other hand, the torque obtainable with a condenser only (as in sketch $C$ of Reed and Koopman's paper) is of the order of 100 per cent of 3-phase starting torque. This means that a 3-phase motor operating from a single-phase line and started as a capacitor motor has starting characteristics comparable with those of a repulsion-start single-phase motor or those of a 3-phase motor. The over-all cost, however, is greater than that of a repulsion-start motor at the present price of condensers.

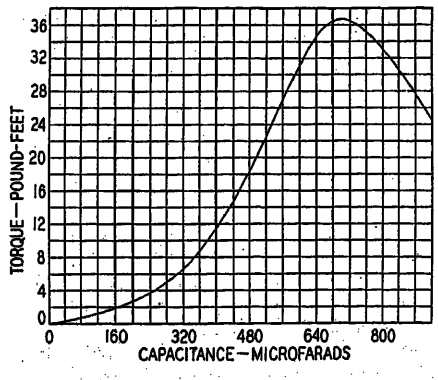
The authors make the statement in the opening paragraph of their paper that their method is "quite different from those which have appeared in the recent literature." The writer would like to state that it appears to him that the procedure used by the authors in treating the 3-phase motor operating single phase and also the 3-phase motor on unbalanced 3-phase supply is essentially the same as that used by O. C. G. Dahl in his book "Electric Circuits, Theory and Applications," volume 1, and also by C. F. Wagner and R. D. Evans in their book "Symmetrical Components." Also the authors' procedure in handling the case of the 3-phase motor operating as a capacitor motor does not appear to differ fundamentally from that used in the paper by Tracy and Wyss quoted at the beginning of this discussion, together with the discussion of this reference by E. M. Sabbagh (in ELECTRICAL ENGINEERING, March 1936, page 285).

**H. R. Reed and R. J. W. Koopman:** Reeves' treatment of the induction motor operating on 4-wire 3-phase with one line open is interesting, especially since this point was raised in oral discussion by Karapetoff. This is not a common method of operating induction motors, and the problem of determining the impedance to zero-sequence current which would flow under these conditions should be of interest. Wagner and Evans in the December 1929 issue of the *Electric Journal* discuss this problem.

The statement by Selby Haar that unbalanced voltages in a polyphase supply system may be a serious matter has been considered by the writers from the point of view of decreased efficiency, in an article in a recent issue of *Electrical World*.

Tracy states that the "best" value of capacitance to have been used in the illustrative curves of figures 5–7 is that which produces maximum torque at starting. In the Tracy and Wyss paper referred to, however, the authors, using inductive reactance starting, state that "By 'best' values of $R$ and $X$ is meant that pair of values which will produce maximum starting torque—or, if such values should be accompanied by an excessive line current, the 'best' values would then be those which produce maximum torque at an arbitrarily fixed line current."

It would seem that the best value of capacitance to be used at starting should be that which would most nearly duplicate 3-phase conditions at the motor. It can be shown that for 3-phase motors with 3-phase



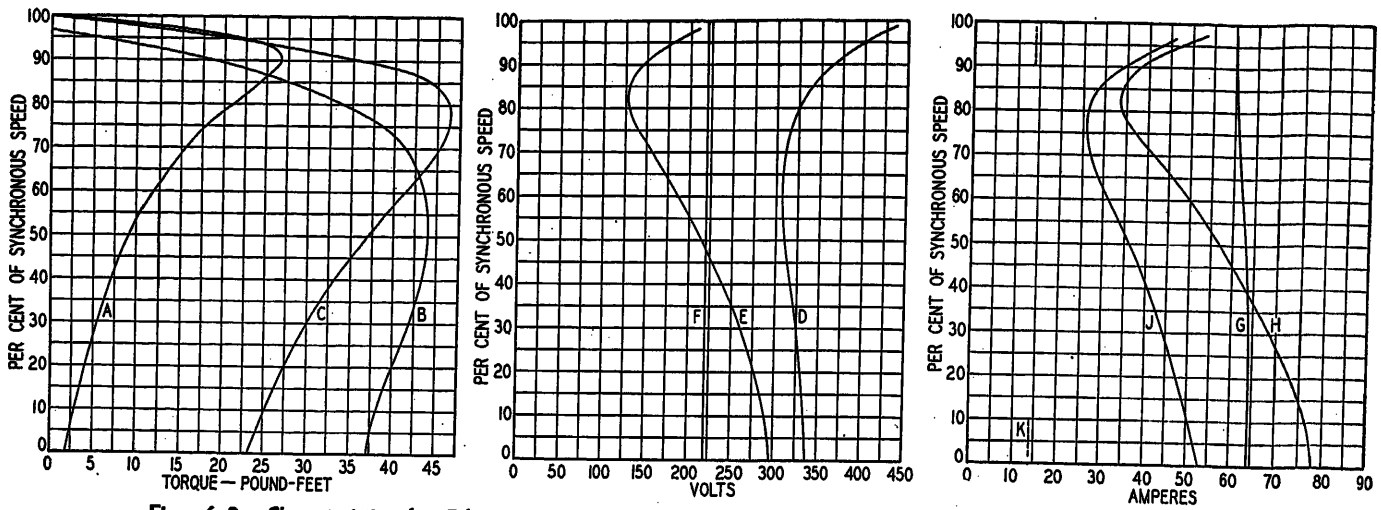


**Fig. 5. Starting torque-capacitance characteristic for 5-horsepower 3-phase motor starting on single-phase supply as capacitor motor**

**Figs. 6–8. Characteristics for 5-horsepower 3-phase motor operating on single-phase supply as capacitor motor**

*A*—Torque, single phase with 160-microfarad capacitor
*B*—Torque, single phase with 700-microfarad capacitor
*C*—Torque, 3 phase
*D*—Terminal voltage $V_{ab}$
*E*—Terminal voltage $B_{bc}$
*F*—Terminal voltage $V_{ca}$
*G*—Current $I_a$
*H*—Current $I_b$
*J*—Current $I_c$
*K*—Rated full-load 3-phase current

starting power factors less than 0.5, exact 3-phase conditions can be reproduced starting single-phase with a capacitor and a series resistor of proper size connected between the free terminal and one line. This resistor should have zero resistance if the 3-phase starting power factor is 0.5. Likewise it can be shown that for 3-phase starting power factors greater than 0.5, exact 3-phase conditions can be duplicated by placing an inductance of proper size between the terminal connected to the condenser (now without a series resistor) and the other line.

The relationship between starting torque and capacitance in microfarads for the 5-horsepower 3-phase 220-volt motor considered in appendix II of the paper is given in figure 5 of this discussion. The curve shows that the maximum starting torque is obtained with 700 microfarads capacitance; applying the expression $X_c = 1.5z$ gives 705 microfarads. The starting torque with 700 microfarads is 160 per cent of normal 3-phase starting torque; but the terminal voltages are 337, 296, and 220 volts, or 153, 135, and 100 per cent, respectively, of rated terminal voltage, and the coil currents are 78, 64, and 53 amperes, or 557, 457, and 379 per cent, respectively, of rated full load current.

Figure 6 is a comparison of the speed-torque curves when the motor operates 3 phase, single phase with the 160-microfarad capacitor, and single phase with the 700-microfarad capacitor. The relationships between the terminal voltages and the coil currents and per cent of synchronous speed are shown in figures 7 and 8 when the motor operates with the 700-microfarad capacitor. These curves show that when the motor operates with the 700-microfarad capacitor at 5 per cent slip it develops only 25.7 per cent of 3-phase torque at the corresponding slip, while the 160-microfarad capacitor it develops 108.5 per cent 3-phase torque. Figures 6 and 7 of the paper show that at this value of slip the currents and voltages are essentially normal whereas figure 7 of this discussion shows that the voltage $V_{ab}$ is 181 per cent of normal. The coil currents from figure 8 are seen to be 429, 339, and 307 per cent rated full load. It is also of interest to note from figure 6 that the no-load slip when operating with 700 microfarads is 3.5 per cent and that the above-named 3-phase torque is produced at a slip of 11 per cent.

In view of the foregoing discussion it would seem to be uneconomical to use a large capacitance, which would cause excessive coil currents to flow and which in itself would have to carry a large current as is shown in the preceding curves. In choosing the value of 160 microfarads to be used in the tests the writers were desirous of obtaining a value of capacitance which would give to the motor operating characteristics which were essentially normal. To obtain such characteristics it was obviously impossible to obtain a high starting torque. In practice, the motor would be started using that value of capacitance which would either give ample torque to start the load or most nearly duplicate 3-phase conditions and as the machine comes up to speed the capacitance would be reduced to a value which gives normal operation. The "best" value of capacitance to use in starting this motor would obviously not be that which produces the maximum starting torque as Professor Tracy indicates in his discussion, and that value would certainly not be used over the working range of the motor.

The expression $X_c = 1.5z$, which gives the value of capacitive reactance to produce maximum starting torque is noteworthy, as is likewise the expression which yields the per cent of 3-phase starting torque.

The writers are cognizant of the fact that the fundamentals are similar to those used by Dahl, Wagner, and Evans, and others. In considering the 3-phase motor operating single phase, Wagner, and Evans combine the sequence networks in an entirely different manner. The paper by Tracy and Wyss deals only with the inductive method of split-phase starting of 3-phase motors and considers neither the capacitor motor nor speed-torque curves, the accurate prediction of which the writers believe to be of paramount importance.

With reference to Trickey's question concerning operation with unequal windings we would refer to reference 3, "Analysis of Unsymmetrical Machines," by Lyon and Kingsley, AIEE TRANSACTIONS, volume 55, May 1936.

In the oral discussion the question of saturation was raised by Karapetoff. The writers believe that this question is adequately answered in the discussions of Corcoran and Trickey.

## Lightning Investigation on Transmission Lines—VI

**Discussion and authors' closure of a paper by W. W. Lewis and C. M. Foust published in the January 1937 issue, pages 101–6 and 189, and presented for oral discussion at the power transmission session of the winter convention, New York, N. Y., January 26, 1937.**

J. J. Smith (General Electric Company, Schenectady, N. Y.): During the last 10 years much work has been done on the problem of lightning interruption of electric-power service and now insulation and protection can be arranged in most cases to reduce tripouts to a very small number. While this progress is due to a number of circumstances it is nevertheless quite outstandingly evident from a survey of recent literature that an important factor has been the introduction of practical measuring instruments for direct connection to the transmission line. At the time the present investigation began there were available almost no direct measurement data which assisted toward an understanding of the problem.

Into this situation was introduced the Lichtenberg figure cameras such as the klydonograph, surge-voltage recorder, and lightning-stroke recorder. All these provided for the measurement of crest values of surge voltages and the determination of

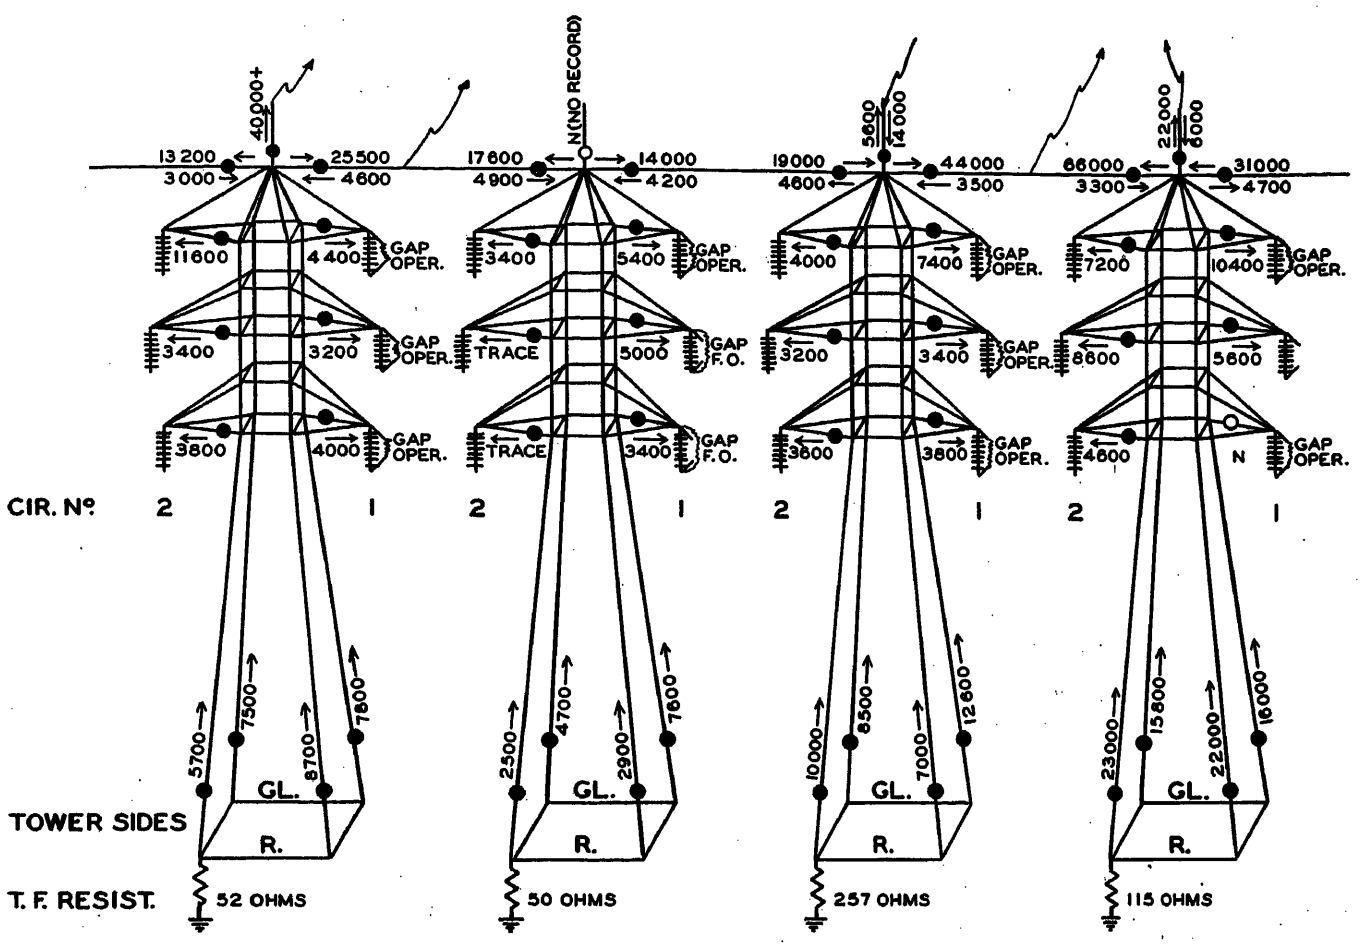

**Fig. 1. Lightning currents measured in towers of 132-kv Glenlyn-Roanoke line, May 4–15, 1936**

polarity. Conductor and structure potentials were then obtained by the hundreds. Lightning surges were followed along the conductor and attenuation directly measured. The Lichtenberg camera as a surge-voltage recorder therefore served to redirect the attack on the tripout problem, to take it away from the desk and laboratory and to concentrate effort on the task of requiring the lightning surge to locate and describe itself through the medium of such recorders.

The surge indicator or flashover indicator followed the surge recorder. This was a device which through the disruption of a small breakable powder link provided an indication of insulator assembly flashover until the patrolman observed it from the ground and reset it for the next flashover. Again many indicators, several thousand in fact, were used and hundreds of insulator flashovers and surges recorded.

The cathode-ray oscillograph was also applied to the measurement of lightning-surge wave shapes on line conductors. The elaborate equipment and somewhat complicated technique of operation required permitted the use of only a few oscillographs. Many valuable wave-shape records were obtained, however, among them one of conductor potential at a point within a few feet of a direct stroke.

All the instruments up to this time were used to obtain information concerning voltage conditions. The accumulating records, however, directed attention toward the necessity for lightning-current measurements and out of this need came the surge crest ammeter. Measurement stations again were established by the thousands. Entire lines were covered and many locations in the line structure such as tower legs, tower arms, overground wires, lightning rods, counterpoise and occasionally even the live conductor. Thousands of records were obtained and these when fitted in with the records from earlier instruments provided a greatly clarified picture of the lightning tripout problem. It is a thoroughly different picture from the previous desk-laboratory picture common at the beginning of the investigation, and this difference is mainly due to the devising of suitable recording and low cost, indicating and measuring devices through which the lightning surge has located and described itself automatically.

Table I of the paper gives an interesting comparison of the tripouts per 100 miles per year on different lines. Some of the differences are due to changed conditions on the same line over a period of years. However, for lines in different localities it is difficult to make a direct comparison since there must exist differences in the lightning conditions experienced. I wonder if the authors can suggest a way of taking these differences in lightning conditions into account.

On page 103 the authors show good correlation between the measurements when voltage exceeded flashover of the insulators and actual flashover. It is not quite clear, however, whether they have experienced flashover in cases where the measured voltage was well below that required. I should like to know their experience in this respect.

**Philip Sporn** (American Gas and Electric Company, New York, N. Y.): This paper is devoted in a large part to presentation and discussion of the field data obtained in the research and investigation that has been carried out over the past 4 or 5 years on the Glenlyn-Roanoke 132-kv line of the Appalachian Electric Power Company. However, the period covered by Lewis and Foust deals almost entirely with records obtained prior to 1936. Some of the most interesting data were not obtained until the year 1936, and in view of the fact that it was not found possible to present these data in summary form at this meeting of the Institute, owing to the shortness of time, it may be interesting to give some of the high lights of the 1936 investigation, and particularly those that bear directly on, and tie in with, the data presented by the authors of this paper.

In figure 2 is shown the magnitude and frequency of lightning stroke currents

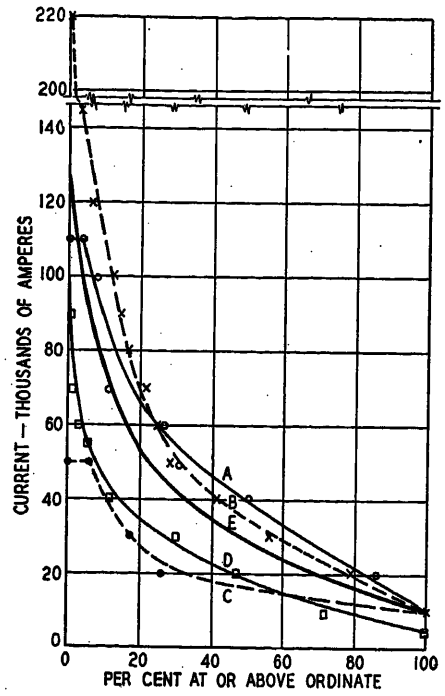

**Fig. 2. Magnitude and frequency of lightning stroke currents, 1933–36**

*A*—By ground-wire currents
*B*—Sum of adjacent tower currents
*C*—By tower-top lightning rods
*D*—Single tower currents
*E*—Average of A, B, and C

measured in the field by 3 different methods namely, currents in the ground wire, by addition of adjacent tower currents, and by direct measurement in tower-top lightning rods. While the current values recorded in this manner show some spread, the average of the 3 curves gives what is believed to be a fair representation of conditions which may be encountered in the field.

A considerable part of the investigation centered around the measurements of lightning currents in counterpoise wires. Figure 3 shows graphically the flow of current along the counterpoises, the counterpoise arrangement being shown in the upper right-hand corner.

The current in the long (150-foot) counterpoise is on the average 4 times the current in the short (40-foot) counterpoise, as measured at the point where connected to the tower. At the free, distant ends the currents are about equal in both. Uniform leakage of current from the long counterpoise is indicated by the averaged data. Clearly the long counterpoise is much more effective than the short one in draining current to ground. Other data, not presented here, indicates the short counterpoise behaving much like a plain ohmic resistance, while the long counterpoise displays an ability to carry current in excess of expectations on the basis of its d-c resistance alone.

An interesting relation between the current in the tower leg and connected counterpoise is shown in figure 4. It might be expected the current in any counterpoise would be less than the tower leg to which it is connected. However, it will be seen this was found to be true of the short counterpoise; but the reverse was true for the long counterpoise, where in some cases the long counterpose at the tower end carried some 30 per cent more than the tower leg. The reason for this has as yet not been fully explained.

Typical field records on which the correlation and interpretation of data were based are shown schematically in figure 1. One interesting feature of this record is the 66,000 amperes found in the ground wire associated with an apparent lightning stroke of 110,000 amperes to the line. Another feature is suggestive of a branched lightning stroke terminating at 2 adjacent towers and also midspan between them. These may, of course, be separate strokes during the same or different storms.

Still another feature of this one record is the high indicated tower potentials at the 4 adjacent towers, 2 of them being 9,800 kv and 8,830 kv, respectively, these being calculated on the basis of tower footing resistance and tower leg currents. Line flashover occurred at all 4 towers, as might be expected.

All this work is particularly interesting from the standpoint of showing what can be accomplished once measurements in terms of fundamental units, and particularly in terms of units of potential and current, are initiated. The great progress made in understanding the lightning phenomena is due in no small degree to the measurement of currents that have been made over the last 3 years under natural lightning conditions, and these in turn as this paper, and as I hope the brief discussion just given has brought out, have been directed more and more toward a detailed study of the various parts of the lightning circuit and an attempt to trace the lightning current from the time it discharges from the cloud until it definitely completes the circuit to ground, and all the current in the various parts of that circuit are accounted for.

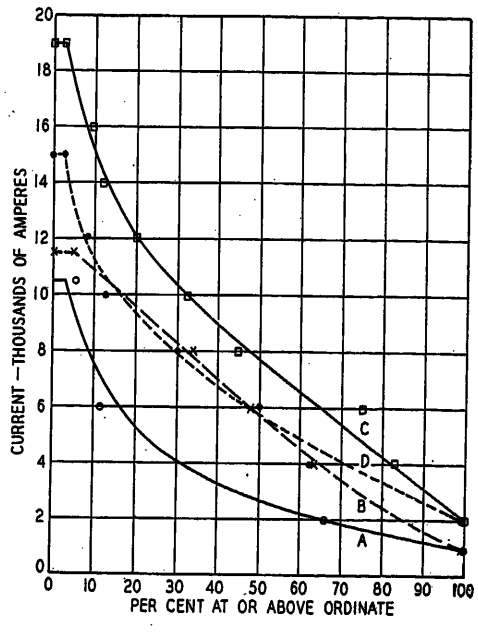

**Fig. 4. Relation between currents in tower leg and attached counterpoise on Glenlyn-Roanoke line, 1934–35–36**

*A*—Short counterpoise
*B*—Short-counterpoise tower leg
*C*—Long counterpoise
*D*—Long-counterpoise tower leg

A great deal more data along this line were obtained in last year's work on the Glenlyn-Roanoke line. A much more complete summary of some of this data, it is expected, will appear in an early issue of ELECTRICAL ENGINEERING.

L. V. Bewley (General Electric Company, Pittsfield, Mass.): In these papers there is the implication that the counterpoise "collects current" or "drains charge" throughout its length. Lewis and Foust, from measurements on 150-foot and 40-foot counterpoises arrive at a *uniform* collection per foot, but Bell shows records over several spans on continuous counterpoises of very irregular collection of current. The authors apparently do not regard the action as a simple traveling wave phenomenon, but rather as a *diffusion* of current up from the ground and along the counterpoise to the tower. That is, instead of a *negative* wave coming down the tower and moving out along the counterpoise, there is a veritable suction of *positive* charge up out of the earth which flows—but not as a wave—toward the tower and on up the lightning stroke to the cloud. Lewis and Foust speak of an essentially uniform potential along the counterpoise, and the natural inference is, then, that the counterpoise behaves merely as a concentrated resistance, presumably equal to its leakage resistance to earth. If

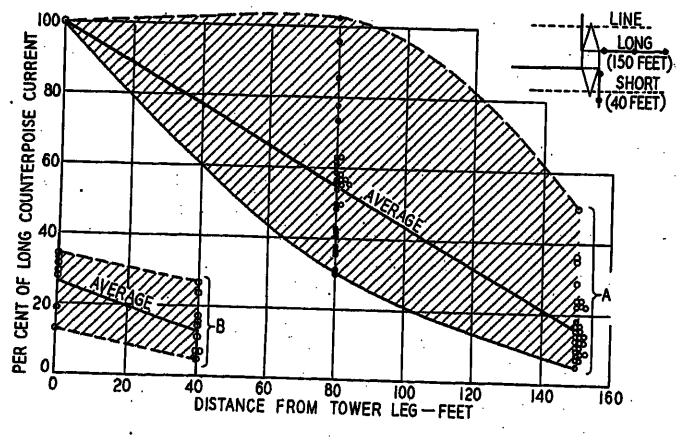

**Fig. 3. Attenuation of lightning currents in counterpoises on Glenlyn-Roanoke line, 1935–36**

*A*—Long counterpoise (30 records)
*B*—Short counterpoise (9 records)

this were so, it would make no difference whether a mile of wire were employed as one long counterpoise, or as many short ones in multiple. Moreover, a sufficiently low leakage resistance would be the only criterion for a counterpoise. For these reasons it seems to me somewhat dangerous to adopt such a point of view; at least until the traveling wave point of view has been found incapable of explaining the results. I therefore wish to demonstrate that the records obtained by the authors are in no wise contrary to ordinary theory and tests on the counterpoise.

It has been shown [1,2,3,4,5,6] both by theory and by field tests that the action of a counterpoise is essentially characterized by 3 effects:

1. The transient surge impedance starts at an initial value of 150 to 200 ohms and decays in a roughly exponential fashion to a final value equal to its leakage resistance.

2. The velocity of propagation is approximately 1/3 the velocity of light, and due to the heavy attenuation, a single reflection is sufficient to equalize a given length of counterpoise, so that a length $x$ is reduced from its initial surge impedance to its final leakage resistance in a time in microseconds equal to 6 times its length in thousands of feet.

3. The coupling with overhead conductors is of minor importance, amounting to less than 10 per cent for a parallel counterpoise.

Assume that a traveling wave $E$ comes down the lightning stroke of surge impedance $Z_0$ and strikes a tower having a counterpoise of transient impedance $Z(t)$. Then according to elementary theory, the voltage and current of the counterpoise are, respectively

$$e = \frac{2\,Z(t)}{Z(t) + Z_0} E$$

$$i = \frac{2}{Z(t) + Z_0} E$$

Obviously, the counterpoise voltage $e$, and therefore the tower top voltage, is a maximum in the neighborhood of the crest of $E$, but the counterpoise current $i$ does not reach its maximum until later. If $E$ were a moderately long wave, $i$ would not reach its maximum until $Z(t) = R$, where $R$ is the final, or leakage, resistance of the counterpoise. Now a surge crest ammeter merely measures the maximum current; and as is evident above, this maximum current *does not coincide with maximum voltage*, because the counterpoise impedance is changing. In other words, the leakage resistance of the counterpoise is not available at the instant of maximum voltage, and therefore the tower voltage will exceed the $RI$ of the counterpoise. The point is illustrated in figure 1, when a 10,000-kv lightning wave with a 1.5-microsecond front strikes a counterpoise. For simplicity the ground wires and tower footing resistance are neglected. The 500-foot counterpoise transient impedance falls from 200 ohms initially to 20 ohms finally in 6 x 500/1,000 = 3 microseconds. By the equations, the voltage is seen to reach a maximum of 2,600 kv at 1.0 microsecond while the current does not reach its maximum of 46,000 amperes until about 2.0 microseconds. If this maximum current were multiplied by the leakage resistance of the counterpoise the result of 920 kv would only be 1/3 the actual maximum voltage.

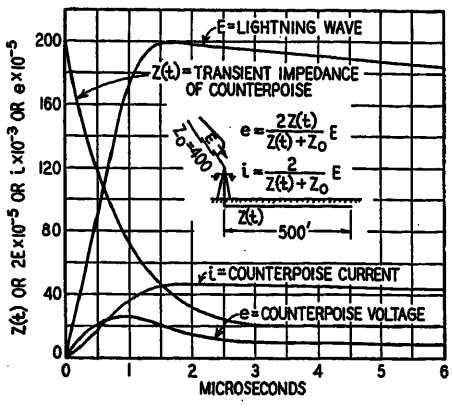

Fig. 5

This also explains why the $IR$ products are usually too small to account for the flashovers known to have occurred, especially in view of the fact that the voltage across the insulators is actually

$$V = (1 - \text{coupling factor})RI$$

and the coupling factor will be from 0.20 to 0.40.

Thus it appears that the observed results are in full accord with the ordinary traveling wave theory and tests of the counterpoise. Nor does the available surge crest ammeter data in itself offer any plausible reason for changing to a "diffusion" theory yielding a very much smaller voltage. It may be remarked, however, that the longer the wave front the more nearly do conditions approach the leakage resistance conditions of the counterpoise, but this is a natural result of wave theory and in no wise a substitution of mechanism.

S. K. Waldorf (Pennsylvania Water and Power Company, Baltimore, Md.): Lewis and Foust present additional evidence that lightning difficulties can be practically eliminated by the use of overhead ground wires and counterpoise. The experience of the Pennsylvania Water and Power Company shows very markedly the efficacy of these lightning protective measures. The Safe Harbor - Westport - Takoma 230-kv. line passed through 1936 without a single outage, making the record of this line only one outage in 5 years. Also the Safe Harbor-Perryville 132-kv line has passed through its second year of operation without any outages occurring in its lifetime.

Of particular interest has been the experience with the Holtwood-York 69-kv line which is a double-circuit steel-tower line having 2 overhead ground wires and a double continuous counterpoise system. Formerly, this line had no overhead ground wires nor auxiliary grounding. Tower footing resistances ranged from 17 to 525 ohms, with an average of 133 ohms. Its operating record was particularly bad, having an average of 19.3 single- and double-circuit outages per year in the 6-year period, 1929–1934, inclusive. After the counterpoise was installed, the maximum tower-footing resistance became 20 ohms, with the average value at 9.2 ohms. In the 1 1/4 lightning seasons since the lightning protection has been added, there have been no outages. This record is worthy of special notice because it indicates that tower lines operating at as low as 69 kv in high-resistivity territory can be made to behave well with counterpoise and overhead ground wires.

P. L. Bellaschi (Westinghouse Electric & Manufacturing Company, Sharon, Pa.): These investigations clarify further the lightning behavior on transmission lines particularly the current distribution in the ground-wire network, the towers and the counterpoise. Perhaps there may be the impression that rather complete data are now available on the lightning protection problem. Practically speaking this viewpoint is correct in a good measure. That more need be known on the lightning

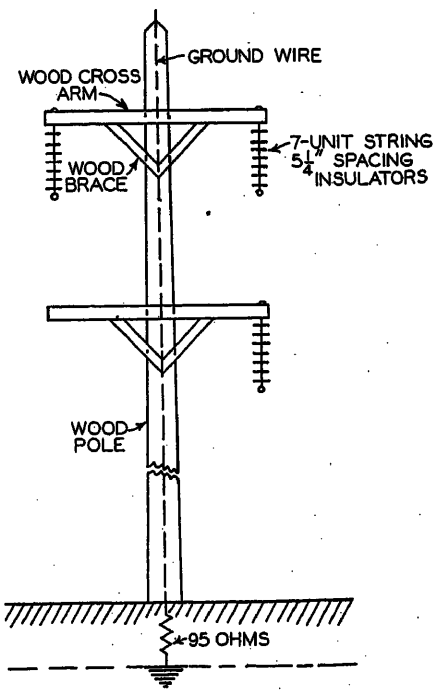

Fig. 6

phenomena even at this advanced stage need hardly be emphasized. I shall illustrate with an example which is rather typical of similar experiences encountered in the study of lightning.

Lightning struck the top end of a wood-pole ground wire (figure 1). Due to the high voltage resulting from the lightning current through the driven ground, flashover occurred from the ground wire to each of the 3 phase conductors. No indication of

flashover was observed at the adjacent poles.

Judging from the data on wood and insulators alone, the voltage time-lag curve for the combined insulation would be quite flat from the full wave (1.5x40 microsecond) down to a few microseconds and essentially the same for positive and negative polarities. Refinements are unnecessary for the purposes here. The estimated strength for the wood cross-arm and the insulator string (figure 1) is in the order of 1,400 kv. Though the resistance of the driven ground at the pole as measured by ordinary methods is 95 ohms, the effective surge resistance when a lightning current discharges through it would be some $^3/_4$ that amount (see for example discussion by Lewis and Foust, ELECTRICAL ENGINEERING, March 1936, page 279). The surge impedance of the 3 lines in parallel is approximately 200 ohms. The accuracy of all these figures are within practical tolerance—amply adequate for this example. The effective impedance from the wood pole-ground wire to zero-potential earth calculates in the order of 40 ohms. The coupling factor between the ground wire and the line conductors is rather small.

By token of the same methods as employed in the investigations here discussed and in other important work, the maximum current associated with the stroke in question is estimated to have been in the order of 50,000 amperes.

Consideration of all the available evidence reveal additional, pertinent information. The tip end of the wood pole ground wire which was struck by the lightning stroke was studied. This is a number 4 soft-drawn copper wire, i.e., 0.20-inch diameter. The tip end was fused and the molten metal flowed down the sides a length equal about the diameter. Evidence of overheating extended down a length of a few diameters. Tests were conducted in the laboratory on a similar conductor. Lightning currents from 50,000 to 100,000 amperes (approximately) and of a total duration of 100 microseconds were applied at an interval apart (2 minutes approximately) sufficient for the tip end of the conductor to cool down between applications. These tests indicate that $^1/_8$ inch of the tip down the side was raised near or to fusion temperature. Besides the oxydized surface extended downward some $^1/_2$ inch.

A close comparison of the field specimen and the samples tested in the laboratory lead to the following conclusions: (*a*) A repetitive stroke consisting of some 3 or 4 discharges apparently hit the conductor; (*b*) The maximum current in the discharges appears to have been in the order of 50,000 amperes.

The data pertaining to figure 4 in a paper by the writer (ELECTRICAL ENGINEERING, August 1935, page 839), similar information of the kind and the recent experiences abroad (Norinder in Sweden) further strengthen the conclusions above.

The case here described would appear to be similar to the 2 cases indicated as items 11 and 12 in table III of the paper by Lewis and Foust. Measurements with the crest ammeter would undoubtedly have contributed information on the crest value of the current but, as in the 2 cases in table III, no information on the "time factor"—an important element in lightning studies. It can be seen from this illustration and from similar cases that could be added that further methods of measurement and analysis than those employed in the investigations discussed are susceptible of giving additional, useful data on the lightning phenomena. This critique does not detract from the valuable contributions by Edgar Bell and Lewis and Foust.

**W. W. Lewis and C. M. Foust:** The authors wish to thank all those who have contributed discussions. J. J. Smith asks about the tie-in between lightning severity at particular locations and tripouts per 100 miles per year as given in table I of the paper. In course of this investigation, lightning-severity meters have been used at several locations over a period of a few years' time. The conclusion reached from their use was that severity does vary greatly at any particular location from year to year. It was not found possible to tie in the severity meter results closely with line performance, particularly because the latter depended so much on line construction. The most interesting scientific information on lightning frequency is obtained with the ceraunograph. These are electromagnetic instruments used by the weather bureau and through which the whole country is marked out in isoceraunographic lines of equal thunderstorm frequency. The transmission lines in table 1 extend over a territory from Albany, N. Y., to Washington, D. C., across New Jersey, eastern Pennsylvania, Maryland, and Virginia. The thunderstorm-frequency average ranged from no thunderstorm days in January to 150 to 200 thunderstorm days in July. The northern end of this territory has an average of about 45 storms per year and the southern end 55 from isoceraunograph records.

Smith also asks if flashovers have been experienced in cases where tower potential is well below that required. There are, according to the best analysis possible, several of such cases, but the preponderance of flashovers are co-ordinated with high tower potentials, and it is on this basis that the conclusions are drawn. It must be borne in mind at all times with regard to such data that correlation of flashover with a current record is never direct and positive unless by chance observation. Where automatic oscillographs are used to locate flashover, a strong evidence of tie-in is obtained, otherwise it is necessary to consider operator's reports, storm data, insulator inspections, tube performance, as well as current records in arriving at a correlation. It is to be expected that occasionally incomplete records do result in wrong correlation. However, these are infrequent, but may explain some of the few correlations of low tower potentials with flashovers.

In Philip Sporn's interesting discussion, attention is called to the case where the long counterpoise carried some 30 per cent more current than the tower leg to which it was attached. The explanation has been advanced that this is due to high currents in cross tower members, occasioned by the unsymmetrical counterpoise arrangement used.

Referring to L. V. Bewley's discussion, the term "diffusion" as a name for the lightning mechanism is inappropriate. We like to call it the Ohm's-law theory if a name is required. True, we do not regard the phenomena as a negative wave coming down the tower, nor do we regard it as a "veritable suction of positive charge up out of the earth." It is considered that, for the main stroke, current flows from the positive potential ground to the negative potential cloud. This conception is the common one of a current flowing from positive to negative. It is realistic to regard the counterpoise as practically at uniform potential in so far as flashover voltages are concerned. The counterpoise resistance to earth, however, is not a "concentrated resistance," but exactly the opposite, a distributed one and low because of it and that is just why it serves its purpose of holding down tower potential. Only by spreading out the conducting earth terminal by such wires at the tower footings is there deliberately achieved a decrease of tower-to-ground resistance. Comparing the extreme of a mile of single counterpoise to a number of short ones in multiple has no practical significance as the condition is not realistic. The sum total effect required is that of reducing the "across ground" voltage drop by reducing ground resistance which is highest immediately at the tower footings. Such a reduction in footing resistance shifts the ground potential up into the air arc.

Pertaining to Bewley's demonstration that records obtained are in no wise contrary to theory and tests on the counterpoise, it is regretted that the proof is not more convincing. Artificial lightning field tests are not particularly interesting in connection with such a proof. These are concerned with a quite different phenomenon from that of natural lightning. A 10,000-kv lightning wave with a 1.5-microsecond front striking a counterpoise is quite imaginary. The coupling factor of 0.2 or 0.4 may be correct or not, it should be measured and quite likely will in process of these investigations. The *IR* products of footing resistance and current are not usually too small to account for flashover, in fact the reverse is true, as we have pointed out, and these potentials are usually high enough to account for flashover.

Bewley's closing sentence is interesting and it is suggested that he consider carefully longer wave fronts, particularly those very slow in building up at the start, and then more rapidly as time increases.

Mr. Waldorf's discussion is valuable in that it calls attention to the usefulness of counterpoise and overhead ground wires as demonstrated by several cases of actual operational experience.

## Electrical Characteristics of Suspension-Insulator Units

**Discussion and authors' closure of a paper by C. L. Dawes and Reuben Reiter published in the January 1937 issue, pages 59–66, and presented for oral discussion at the power transmission session of the winter convention, New York, N. Y., January 26, 1937.**

**W. M. Goodhue** (Harvard University, Cambridge, Mass.): The curves obtained by the authors are remarkable in involving linear relationships, and particularly in

using *absolute* humidity instead of relative humidity as the variable. As is well known, the moisture content (including adsorption as in vegetable fibers, glass surfaces, etc.) of materials is not related to the absolute humidity, since materials tend to evaporate their moisture when the temperature is raised, just as water itself evaporates more at a higher temperature. Evidently some mechanism other than the moisture itself, but dependent on the moisture and *temperature*, is acting to counteract the effect of relative humidity.

The authors suggest that the island deposits are sputtering of the pin or cap metal in conjunction perhaps with chemical action. It would be important to know the effect of temperature on this action. A large increase of action with temperature increase would compensate the effect of temperature in reducing the relative humidity, when the absolute humidity is constant, and thus make absolute humidity the nearest significant variable, as it has been shown to be experimentally. A new avenue of experimentation would be to study corona sputtering itself, over a wide temperature range (say 20 degrees to 100 degrees centigrade), with temperature and absolute humidity as variables; something very practical may result from a *pure scientific investigation* of corona sputtering.

Time lag or hysteresis in corona measurements have doubtless been noticed in many types of apparatus. Some measurements that I made on *flat uniform dry air films* involved time lag. Evidently the authors have revealed new causes of hysteresis, so that in insulator work we have now a very large list: corona itself (electrical action), composition of the surrounding atmosphere (chemical change), *sputtering* (*islands*, surface action), heat (due to power loss), humidity (moisture acting merely as surface conductor), etc.

**M. G. Malti** (Cornell University, Ithaca, N. Y.): The results of this excellent paper recall to mind similar curves obtained on various insulating materials, as early as 1893, by Janet,[1] Potter,[2,3] Morris,[2,3] and others.[4-12] Many writers[13-18] have observed a hysteresis effect in the resistance of dielectrics with varying voltage gradient,[14,15] varying temperature,[13,18] varying mechanical pressure [15] and varying humidity.[17] The dielectric permittivity is also known to reveal a hysteresis effect with voltage gradient[19] and with temperature.[21,22] Finally the loss in dielectrics displays a hysteresis effect with temperature.[22,23] These are only a few of the many hysteresis effects that have been known to men interested in the study of dielectrics. The present paper adds the fact that porcelain and glass insulators display hysteresis effects in their loss, power factor, and capacitance when these are measured with varying voltage, varying mechanical pressure and varying degrees of humidity. These results are both interesting and significant. But I believe the authors could have laid more stress on the hysteresis and the hystero-viscosity phenomena in their interpretation.

It is impossible to interpret the hysteresis effects of figures 3 to 7 and 10 to 14 by the circuit figure 2 of the paper. This circuit owes its origin to Maxwell who used it as a model to interpret absorption and loss in

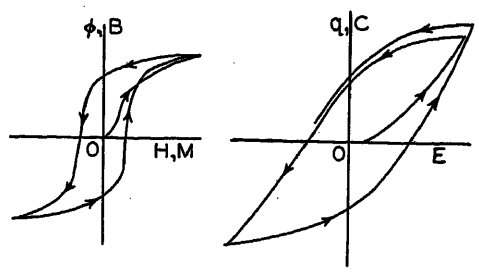

**Fig. 1a (left). Magnetic hysteresis**

**Fig. 1b (right). Dielectric hysteresis**

dielectrics. It served its purpose for a time. But very soon it became evident that dielecrics had properties which cannot be interpreted by such a simple model. This model has therefore been discarded and, to physicists, is now of historical interest only.

To interpret the results of this paper, as well as those of the researches mentioned in the bibliography, quantitatively would require an elaborate theory which we do not, at present, possess. A general qualitative interpretation, such as the authors have attempted, may be readily given on the assumption that dielectrics possess hysteresis just as magnetic materials do. In order to make this statement more real let us examine dielectric and magnetic hysteresis side by side to see the analogy.

In figure 1*a* is shown a magnetic hysteresis loop plotted with $B$ against $H$ which, by a change of scale, can be converted into $\phi = BA$ against $M = Hl$. Now, we engineers work directly with the $B$-$H$ curve. We never say that such a curve can be imitated by a model consisting of a series-parallel combination of pure inductances and pure resistances. The hysteresis loop is sufficient unto itself, is accepted as a physical fact and dealt with directly with no intermediate models to obscure the facts or becloud the issue.

Dielectrics display a similar behavior as shown by this paper and references 1–12. Indeed figure 1*b* is taken from reference 12 and represents the charge $Q$ plotted against the potential $E$. The hysteresis effect is unmistakable. Moreover, if we take the charge $Q$ figure 1*b*, as corresponding to the magnetic flux $\phi$ (figure 1*a*) and the voltage $E$ (figure 1*b*) as corresponding to the magnetomotive force $M$ (figure 1*a*), the analogy becomes irrefutible and complete.

Now the phenomena described by the authors in their figures 3 to 7 are purely dielectric hysteresis phenomena and show a part of the hysteresis loop figure 1*b*. Indeed the capacitance curves figure 3 and figure 6 of the paper can be easily shown to be simply hysteresis loops similar to figure 1*b* of this discussion by the following simple transformation:

We know that $q = ce$. Hence for any $e$, $q$ varies as $c$. Thus by merely changing the scale in figures 3 and 6 the curves $c$ versus $e$ may be changed to $q$ versus $e$, which are, respectively, the abscissa and ordinate of the curve figure 1*b*.

One more word about this research. The authors have an excellent experimental setup but they have introduced so many variables that their work has lost much of its fundamental importance. It is well known[24] that the following factors affect the capacitance, loss, and power factor of a dielectric: (*a*) voltage gradient; (*b*) shape of voltage wave; (*c*) time of application of voltage; (*d*) frequency; (*e*) temperature; (*f*) mechanical pressure; (*g*) humidity; (*h*) ionizing radiation; (*i*) shape of material; (*j*) shape of electrodes; (*k*) material of electrode; (*l*) electrode area; (*m*) thickness of dielectric; (*n*) physical condition of dielectric; (*o*) chemical composition of dielectric; (*p*) ionizing radiations.

Several of these factors entered simultaneously into the research under discussion and no attempt was made to eliminate all but one factor. For this reason the results cannot be generalized and must be restricted, in their application, only to the conditions under which they were taken.

**Sidney Withington** (New York, New Haven, and Hartford Railroad, New Haven, Conn.): This paper has developed insulator characteristics of much interest, and the authors are to be complimented for their contribution to this very important subject. It is to be hoped they will continue their tests, and that their work will inspire others.

It is apparent, as the authors have stated, that in the case of the 2 insulators tested, each, it is understood, rated at 18,000 pounds a definite change of some kind occurs in the porcelain insulator at approximately 8,000 pounds and in the glass insulator at about 12,000 pounds. Any such change, while undoubtedly very small in extent and observable only in the laboratory, nevertheless may be of considerable interest and *may* indicate some slight damage to the porcelain or cement connection.

The loads at which this change occurs may be within the range of loads imposed under service conditions, especially in the case of the porcelain insulator, when this point occurs at less than half the designed M. and E. stress. Even if, as intimated by the authors, the change is due only to some readjustment of the pin, the cement and the compound used for sealing, nevertheless if this readjustment is recurrent each time the stress passes this point, there may ultimately be serious deterioration.

It would be of much interest I believe to continue these tests with other types of insulators to determine whether or not this is a general characteristic.

**J. J. Torok** (Corning Glass Works, Corning, N. Y.): This paper by Dawes and Reiter is quite interesting and timely. Some of the effects which they describe have previously been recognized and in some cases well understood. However, so sporadic was the work in this field that important secondary effects have been frequently overlooked.

The effects of the so-called island deposits can be often detected by radio interference measurements in the following manner:

The radio interference level of a clean insulator is first obtained. Then a voltage, slightly below flashover is applied for 5 minutes or more, after which the radio interference is again obtained. It will be found that the interference level after the application of voltage is somewhat higher than when the insulator was first tested. This rise in interference level is due to the deposit raising the surface conductivity around the pin and head of the insulator and reducing the gradient adjacent to the metal parts. The increase in surface conductivity seems to last for a considerable period of time.

Tests in which glass pin type insulators have been subjected to abnormally high voltages for periods of years show that the surface of the glass has not changed. This, of course, would be expected from the known chemical resistivity of glass. However, the tie wires and even the large conductor attached to the insulators were corroded. Apparently the acid depositing on the metal parts hastened the corrosion. This effect at first seemed quite rapid but after a period of several months when the protective coating was fully formed the rate of deterioration was considerably reduced. The lead head pins on which the insulators were mounted were likewise corroded. The conductors and pins on the no-static type of insulators that were included in these tests were practically free of corrosion, only the natural oxidation seemed to have taken place. The conducting layer in the pin hole and around the head eliminated the corona and prevented corroding acids from forming.

The study of electrical characteristics with varying loads, as the authors point out, shows only that relative movement between the hardware and porcelain or glass does take place.

One of the difficulties of measuring the loss in a sample dielectric is in obtaining an intimate bond between the electrodes and the dielectric. If the electrodes are not thoroughly bonded to the dielectric the resultant voids bring about losses and other inaccuracies of measurement. These factors in higher voltage measurements may even overshadow the losses in the dielectric. Therefore any slight movement of the cap or pin causing a change in the bond between the electrodes and the dielectric should be detected by power factor or capacitance measurements.

A study of the effects of mechanical loading on the electrical properties of glass has been made by Doctor Guyer and the results published in the *Journal* of the American Ceramic Society in 1933. In brief he found that mechanical stresses set up by shear, cantilever, or pure compression did not affect the electrical conductivity of glass. The variations in the properties of the insulator as shown in figure 13 are therefore undoubtedly caused by slight readjustment of the alloy both in the pin hole and in the cap.

**Philip Sporn** (American Gas and Electric Company, New York, N. Y.): The authors of this paper have done an excellent systematic and painstaking job in investigating the subject of insulator characteristics a hitherto altogether too neglected field. It is astonishing to find electrical characteristics of suspension insulators such as power factor, capacitance, watts loss, following a hitherto undiscovered trend detected here by the accurate measurements of small quantities under controlled laboratory conditions.

It is of course too soon to predict where this study of porcelain-insulator characteristics may lead us but the fact that the authors have developed and applied a technique for insulator testing ought, without doubt, to be of considerable benefit to the particular art and to the particular industry in general.

Specifically the application of this method of testing ought to be of great help in design testing of insulators, both present and new types, with a view of detecting those physical characteristics which are not obviously measurable but which do have an appreciable effect in determining insulator deterioration and insulator life. We, ourselves have carried out some work in this connection but the amount of further work to be done is astonishingly large and the handicap that we have been faced with heretofore owing to lack of proper instruments and technique ought to be at least partially removed by the application of some of the methods already disclosed by the authors and by a development and perfection of these methods. It is hoped that the authors themselves will continue their systematic research on insulator characteristics. I personally believe that the results so obtainable will be of considerable benefit to the electric power industry and to the electrical industry in general.

**C. L. Dawes and R. Reiter:** W. M. Goodhue states that it is remarkable that our power factor-absolute humidity characteristics are linear. We felt this same way when these characteristics were first obtained and in order to verify these relations we performed a considerable amount of experimental work over considerable periods of time and under wide ranges of atmospheric conditions. Moreover, data obtained by graduate students who conduct insulator tests as part of their laboratory work show this same linear relation, so that it seems to be an experimental fact. There has not, however, been opportunity to determine whether or not this relation is due to any fundamental law.

The material in this paper first appeared as part of a doctorate thesis, and specific humidity, rather than absolute humidity was used as the humidity parameter. The same linear relations of power-factor to humidity were obtained, however. The change to absolute humidity was made at the suggestion of the Institute Committee in order to conform to previous practice. Over the usual range of atmospheric conditions, the ratio of specific to absolute humidity is nearly constant, so that the character of the curves is not appreciably affected by the change. Goodhue states that evaporation from materials tends to increase with temperature just as water itself evaporates more at higher temperature, and the inference is that the insulator characteristics would seem to be functions of relative rather than absolute or specific humidity. This conclusion is logical and our initial reasoning was the same as his. Hence, as stated in the paper, every attempt was made to relate our chatacteristics to relative humidity, but we could find no definite relation. Fundamentally, with the insulator the phenomenon is one of adsorbed moisture. Surface adsorption of gases is often considered a physical effect and the gases adhere rather tenaciously to a surface. Possibly the relation of adsorbed moisture to temperature is quite different from that of water vapor intermingled with the atmosphere, which may be the explanation oft he fact that the characteristics are not directly related to relative humidity. There may be some temperature effect which is not yet known.

Goodhue feels that it would be important to know the effect of temperature on the sputtering action of corona on the metal wire and cap. This would, of course, be valuable as fundamental knowledge and might assist in the explanation of the humidity effects obtained. However, in our tests, although the temperature varied several degrees, the proportionate change in absolute humidity was very much greater than the proportionate change in temperature. Hence, the authors feel that the changes in humidity must have a much

greater effect on sputtering than does temperature.

The lag in corona measurements observed by Goodhue is undoubtedly due to the fact that corona formation is in part determined by the ionization conditions in the ambient air. It requires time for the number of free positive and negative ions in the ambient air to reach the steady-state value. The lag found by us is due primarily to the time required for the temperature of the surface to change and to the time required for the accumulation of surface deposit. In both cases lag is due to the fact that appreciable time is required for conditions to reach equilibrium. In his concluding comment, Goodhue summarizes quite completely the several factors contributing to the "hysteresis" effect.

In M. G. Malti's discussion, he has apparently confused the lag or hysteresis effect shown by us with the cyclic hysteresis occurring in magnetic and dielectric materials. Although both phenomena involve lag of the effect relative to the cause, the two are quite different phenomena. With magnetic and dielectric materials hysteresis involves molecular rearrangements and also storage of energy. The hysteresis observed by us is merely a lag of surface conditions with respect to the effects producing them, and no energy is stored at any part of the cycle. In fact, it is being dissipated continuously at each point on the hysteresis cycle. In the porcelain itself true dielectric hysteresis of course does occur, but this is a rapidly changing cyclic phenomenon, and except for the almost negligible energy loss, its effects do not appear in our steady-state measurements.

The circuit shown in figure 2*a* is not the usual Maxwell series-parallel combination of resistances and capacitances purporting to simulate the behavior of dielectrics when an electromotive force is impressed on them as stated by Malti. The circuit is an actual one consisting of true surface resistance in series combinations with the actual capacitances between the surfaces of the shell. Accordingly, the circuit is not a model and it can be replaced by the equivalent circuits of figures 2*b* and 2*c*, just as electrical networks can usually be replaced by more simple circuits.

The hysteresis effect shown in our capacitance characteristics as stated in the paper is due to the fact that changes in surface resistance vary the amount of effective shell capacitance in circuit between cap and pin. This does not involve the ratio of $q$ to $e$ in the same sense that it occurs during the cyclic changes in dielectrics.

In the last portion of his discussion, Malti enumerates the several factors which affect the results obtained by us and states that the work lacks fundamental importance. Most of the factors which he enumerates have been investigated in a fundamental manner and are represented by a large amount of published data, some of which are given in his bibliography. Yet so far as we know, up to now no one has been able to apply these data to a porcelain insulator to reach the conclusions given in the paper. It must be remembered that this is practically pioneer work in this particular field, and it is only due to these experiments with complete commercial insulators that we now know the several factors which affect the insulator characteristics. We have already been able to isolate some of the factors suggested by him and hope to publish these in a subsequent paper. We realize that these experiments have opened a wide field of research, as Malti's suggestions imply, and undoubtedly as time progresses, more will be known of the subject.

Sidney Withington refers to the effect of mechanical load on the electrical characteristics of the insulator. As he states, at certain loads there is a definite but small change in these characteristics. We agree with him that since these changes show some readjustment of pin and the cement they may be of some importance. In the time available we did not investigate this effect nearly as completely as we would have desired. He suggests that the effects of mechanical loading should be studied under recurring stress. We have done this to a limited extent, but the work should be carried much further to include several different designs of insulators and tests should be made under varying electrical stress and at different temperatures.

It is gratifying to learn from J. J. Torok that the results presented in the paper substantiate some of the effects noted in the past, such as radio interference. In fact, our discovery of the island deposits such as are shown in figure 8, and the statement that they cause radio interference, seem to be in accord with the measurements of radio interference, which he describes. His statement that the surface of glass does not change after being subjected to abnormally high voltages for periods of years we assume does not mean that the surface is immune from the surface deposits described in the paper. Although there was not opportunity to examine the surfaces of the glass insulator with the care devoted to the porcelain, the characteristic shown in figure 7 would indicate a pronounced surface deposit.

The information obtained by Doctor Guyer that the mechanical loading of glass does not affect its electrical characteristics shows that the changes in electrical characteristics shown in figure 13 must be due to readjustment of the alloy at the pin and cap.

It is also very gratifying to learn that Philip Sporn, who has had wide experience with insulators in service and under diverse operating conditions, feels that our work will be of considerable practical importance. We are continuing the work and hope that further developments in our technique will be of assistance in improving the design of insulators and in detecting faulty insulators.

## Lightning Protection for Transmission Lines

**Discussion of a paper by A. W. Gothberg and A. S. Brookes published in the January 1937 issue, pages 13–16, and presented for oral discussion at the power transmission session of the winter convention, New York, N. Y., January 26, 1937.**

L. V. Bewley (General Electric Company, Pittsfield, Mass.): The analysis given by the authors is based on a lightning stroke of constant magnitude (40,000 amperes) with a uniform rate of rise of 1,000 kv per microsecond. Figure 1 of this discussion shows the results of some calculations for the equivalent of 8 standard 10 x 5.75 suspension insulators based on assuming definite front lightning waves of 1-2-4 microseconds and the lightning expectancy curve given in "Flashovers on Transmission Lines," ELECTRICAL ENGINEERING, April 1936.

These curves take into account the tower-footing resistance, surge impedances of phase wires and lightning stroke (400 ohms), coupling factor, time lag of insulator flashover, and a "crest factor" depending upon the length of spans, lightning wave front, and successive reflections.

The left-hand curves give the percentage flashovers for a stroke to a protected pole, the middle column for strokes to an unprotected pole midway between protected poles, and the right-hand curves the consolidated results. The following conclusions may be drawn:

1. The longer the lightning wave front the fewer the flashovers, a 1-microsecond front causing

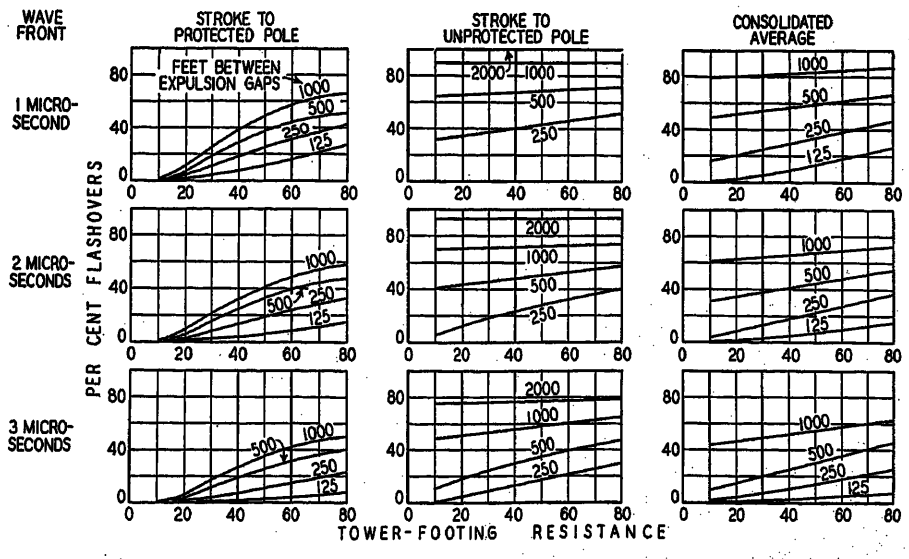

**Fig. 1. Per cent flashovers for stroke to protected and unprotected poles with expulsion gaps on top phase only and with ideal shielding, 125-foot spans and 10- by 5.75-inch insulator units**

perhaps twice as many flashovers as a 4-microsecond front.

2. The lower the tower-footing resistance the fewer the flashovers. But the curves are rather flat and the benefits of low footing resistance are by no means as good as in conventional ground wire practice. The reason is that resistance plays a minor rôle for a stroke at or near a pole not equipped with an expulsion gap, and as the number of unprotected poles between gaps increase, the bulk of flashovers become more independent of resistance. A stroke to an unprotected pole corresponds to a midspan stroke to a ground wire, with the essential difference that midspan flashover requires a very high voltage, whereas flashover of the insulation at the pole is comparatively small. The curves show that a reduction of resistance is about equally beneficial, regardless of wave front.

3. The percentage flashovers increase as the distances between gaps become greater, thus confirming the contention that the gaps should be installed at short intervals to realize their full advantages. Thus for a 2-microsecond wave front and footing resistances of 40 ohms the flashovers are:

| Distance Between Gaps | 125 | 250 | 500 | 1,000 |
|---|---|---|---|---|
| Per Cent Flashovers | 4 | 18 | 42 | 67 |

## Lightning Investigation on a 220-Kv System—II

**Discussion and author's closure of a paper by Edgar Bell published in the December 1936 issue, pages 1306–13, and presented for oral discussion at the power transmission session of the winter convention, New York, N. Y., January 26, 1937.**

**L. V. Bewley:** See discussion, page 626.

**P. L. Bellaschi:** See discussion, page 627.

**S. K. Waldorf** (Pennsylvania Water and Power Company, Baltimore, Md.): The surge current measurements on counterpoise conductors reported by Bell are of great value and more of them are needed, because they give an indication of the answer to one of the open questions in the design of lightning protection for transmission lines. This question is the proper length for counterpoise conductors. Bell has shown that currents flow along the counterpoise toward the point of stroke contact from as far away as $1^1/_2$ miles. This is a remarkable condition with tower footing resistances being as reported between 1 and 2 ohms. It would seem that such low footing resistances would permit neutralization of charge in the vicinity of a tower without charge flowing along the counterpoise for long distances. If such were the case, counterpoise conductors would not need to be so long.

The records presented in figure 2 of the paper must have been caused by a stroke having a relatively slow rate of voltage rise. Several microseconds must have been required for charge to travel more than a mile to the struck tower. The current law of Kirchhoff was followed at junctions of counterpoise and towers, a point not at first clear, as surges travel with different velocities on unburied and buried conductors. Maxima of surges on overhead ground wires and buried counterpoise under these conditions would not occur simultaneously at junctions, and the crest surge currents recorded would not obey Kirchhoff's current law. Apparently this effect did not enter into the measurements reported, indicating slow rates of current change.

The matter would be clarified to some extent if Bell would give details of the measurement of tower footing resistances on the line, such as amount of counterpoise and overhead ground wire included in the protective system during measurement and the reference used for the measurement. On this depends the conclusion which can be drawn whether the behavior noted is common to all types of counterpoise installation or only to counterpoises installed in soil of high resistivity.

**Edgar Bell:** Surge-crest ammeter records are not precision measurements and only tell the maximum or crest value of current without any indication of the time at which this maximum occurred, nor any direct indication of the current wave shape. Present technique allows any measurement to have an uncertain error; and the degree of accuracy of any single measurement is unknown. In general, however, surge-crest ammeter measurements appear to be consistent and reliable, but they have their limitations. Consequently, although the fact that the crest magnitudes of currents at various junction points in the overhead ground wire-tower structure-ground network apparently obey Kirchhoff's law, the accuracy of measurement does not permit us to say that reflections did not occur, but merely that such reflections were not particularly large.

Measurements of tower footing resistance were made during 1929 on the 14-tower section of line now equipped with continuous counterpoise. These were made under 4 conditions, namely:

1. Before installation of counterpoise, and with overhead ground wires disconnected from the tower under test.

2. Same as (1) but with overhead ground wires in place.

3. After installation of counterpoise and with overhead ground wires disconnected from the tower under test.

4. Same as (3) but with overhead ground wires in place.

Summarized results were as follows:

| Method | Maximum Ohms | Minimum Ohms | Average Ohms |
|---|---|---|---|
| 1 | 150 | 50 | 93 |
| 2 | 3.0 | 2.1 | 2.5 |
| 3 | 1.6 | 1.0 | 1.4 |
| 4 | 0.8 | 0.8 | 0.8 |

These resistance measurements were made with a megger ground tester. Measurements made in 1926 using a Kolrausch bridge and before overhead ground wires were installed gave approximately the same results as method 1.

The 1935 and 1936 counterpoise-current measurements show that currents flow for long distances, (except for extremely small lightning discharges) and indicate that lightning surges have relatively slow rates of voltage rise. The numerous records obtained some years ago from lightning stroke recorders also suggest that lightning strokes themselves do not have as rapid wave fronts as formerly assumed. Consequently the megger resistance measurements, except for the fact that they were made at low voltage and small current, more nearly approximate the resistances existing under lightning conditions than if lightning surges were of steep wave front.

## First Report of Power System Stability

**Discussion and closure of a report of the AIEE subcommittee on interconnection and stability factors published in the February 1937 issue, and presented for oral discussion at the power transmission session of the winter convention, New York, N. Y., January 26, 1937.**

**A. C. Monteith** (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): The committee should be congratulated on the completeness of this first report on a very broad and involved system problem.

The vital facts are presented for a large number of systems already in operation. The introduction of the a-c calculating table has given a tool that simplifies the solution of involved systems being planned. Its use has allowed a very accurate treatment of the interconnection and stability problem

**Fig. 1**

(a)—Zero ohms tower-footing resistance
(b)—3 ohms tower-footing resistance

with considerable saving in time and also the elimination of the human factor from a large part of the solution. The attached figure not only illustrates the results obtained from the a-c calculating board on a particular 6-machine problem but further shows the effect of considering 3 ohms tower-footing resistance in the zero-sequence circuit for a fault just outside station 1. This is a very nominal amount of resistance and its consideration in this case saved going to higher speed breakers or the use of higher speed relaying.

In another study the system was stable when 5-cycle breakers and carrier-current relaying was used assuming no tower-footing resistance. The system was in a high-resistance area and no ground wires were contemplated. The consideration of 10 ohms tower-footing resistance allowed the use of standard 8-cycle breakers and impedance-type relays resulting in a large saving in the equipment. The value of resistance selected and when it can be used

will depend on the particular system under consideration.

The effect of tower-footing resistance is emphasized in this discussion to point out that the proper consideration of ground resistance sometimes permits the use of less expensive equipment. It is possible also that data of this character might have been collected from the operating companies and included in table III.

**E. F. Scattergood** (Bureau of Power and Light, City of Los Angeles, Calif.): This report has been of particular interest to me because the field covered and the results presented so closely parallel the similar work done with respect to the design of the Boulder Dam transmission system of the City of Los Angeles.

In connection with the study of system stability, a point that should receive special consideration in the future is the effect of the characteristics of system load. A considerable part of the load on a metropolitan system is not pure resistance or pure impedance but consists of induction motors. Under the lower voltages existing during the recovery period after the fault, such motors tend to draw increased currents, a condition unfavorable to system stability.

To account for this effect on our system in an approximate way that was reasonably easy to apply, the system load was assumed to be 40 per cent motor load; and the load conductance representing this portion of the total load was assumed to vary inversely as the square of the voltage at the load during the recovery period.

Power limits found by this method are about 15 per cent lower than if the usual assumption of fixed impedance load is made.

Also in connection with table III of the paper, I should like to made certain corrections with respect to item I, the Boulder Dam-Los Angeles line: Line *A*-4 should read 265,000 kw.

This corresponds to the minimum head rating of the 4 turbines. The value of 240,000 kv which you used is the operating capacity representing load delivered at the receiving end. This is taken as 0.8 of the theoretical stability limit determined as outlined in greater detail in my paper given in your bibliographical reference 158.

In line *C*-2, the short circuit ratio should have been given as 2.74 at 60 cycles.

In line *F*-5, in designating use of lightning arresters, it should have read: at terminal stations, yes; at switching stations, no.

**C. W. Franklin** (Consolidated Edison Company of New York, N. Y., Inc.): In discussing methods of increasing the stability of metropolitan power systems, the "Report of Power System Stability," includes the system arrangement known as "synchronized at the load." Since this arrangement was placed in operation in the New York area in 1929, it is felt that a review of operating experiences in this area and the modifications resulting from those experiences should be helpful to those contemplating such an arrangement.

In the original concept of a system of this type, each generator was connected to a group of feeders and thence to the load. The only paralleling connections between generators were to be at the load, which in the ultimate, would be the low-voltage network mains, and during the transition period would also be through the low-voltage busses at substations. Service continuity was assured by the segregation of sources and the connections to a given network were deversified between as many bus sections as were available in a generating station and where economically feasible, also by feeder connections to 2 stations. Circuit breaker duty was greatly reduced due to the high impedance of the connections between generators. Economical loading of generators was accomplished partly by rearrangement of station switching and in part by unbalancing feeder loads. Stability both steady state and transient was assured by calculation, test, and subsequent experience.

In attempting to operate generators and stations at their economic loadings, some unbalancing and thereby overloading of network transformers resulted, and difficulty was experienced due to premature operation of network protectors at light loads. Late in 1930, while transferring load from Hudson Avenue to Hell Gate, the substation connections opened and the accompanying unbalance on network transformers and mains in one of the districts resulted in some equipment damage.

As a result of these experiences, it was decided that there should be no load transfer through the high-impedance connections. Stations and sections within the stations were to be operated substantially in phase and economy transfer was obtained by switching within the stations and between stations, by direct tie feeders with load control devices.

The maximum size of network which could be re-energized after shutdown had long been a matter of concern and study and the system was therefore divided into a number of separate low voltage networks, several of which were supplied from 2 stations. The difficulty of co-ordination between different stations during system trouble led to the conclusion that quicker restoration would be effected after an interruption if each network is under the control of one operator and thereby supplied from one station.

As a result of these experiences we have adopted the following as our fundamental plan of system development. Generating stations will be interconnected by a system of direct tie feeders and the distribution load will be segregated into blocks which are small by comparison with the capacity of the interconnected stations.

1. The a-c network will continue to be divided into network areas, each area being completely segregated from all other network areas. The load in each area should be small enough, so that the area can be re-energized by the station which serves as its base supply. Stations will be properly subdivided to meet the following requirements.

2. Network feeders should carry load in only one network area and should not be bifurcated with feeders to other areas.

3. The supply to each network area should be distributed between 2 or more major bus sections and further distributed among 4 or more subsections, and network capacity provided so that each network area fed from the station may be carried in emergency with one major section out of service. If the station has 3 or more major sections, it should be possible to re-energize a dead network area with one major section out of service. Each major bus section or subsection should have complete automatic protection.

4. Each network area should be supplied from a single station except during periods of initial development when the station has insufficient facilities to meet the above requirements. When it is necessary to feed an area from 2 or more stations, the supply should be such that one of the stations can pick up and carry the area in emergency without the other stations. This requires that the base station should have connected to it at least ½ of the feeder and distribution transformer capacity to the area.

5. Ties between stations should be adequate to pick up and carry the load of certain predetermined network areas fed from a station temporarily out of service due to mechanical trouble. These ties will generally be of capacity required for normal operating purposes such as economy of operation and pooling of reserve capacity.

A network system of this type has the following merits:

1. It is simpler to operate under normal conditions than any other type of system.

2. It requires a minimum of voltage and phase-angle control devices.

3. It minimizes the amount of operating co-ordination required for the restoration of service in the event of interruption and correspondingly simplifies the operating rules covering the re-energizing procedure.

4. In the event of the loss of communication or failure of the interconnections between stations, it enables each station to operate as an independent unit which in most cases will be able to supply all the load to the network areas which it serves.

5. It offers great flexibility in planning the expansion of the system.

To satisfy the above principles a station must be electrically segregated so as to substantially provide the equivalent of three or more stations at one location. This requires segregation of the switch and bus galleries by fire walls, so that fire will be confined to a small section of the station. In addition to automatic bus protection, any connections between major sections should be indirect physically and should have sufficient sets of automatic protection in the link to preclude the spread of electrical trouble. It is also desirable, if practical to sectionalize or make provision for quick sectionalization in case of failure on a steam or water main.

The work necessary at Hudson Avenue to satisfy these principles is practically complete and the new Waterside 60-cycle installation is being made in accordance with the fundamental plan. Plans for the revamping of Hell Gate are complete whereas plans for the rebuilding of the Sherman Creek galleries are being formulated. Further sectionalization of the network proceeds whenever the load in an area exceeds the permissible limit.

**R. D. Evans:** Franklin's discussion of the system arrangement known as "synchronised at the load" is of considerable interest. While the report referred to this method principally for the purpose of illustrating a principle applying to system arrangements, it is pertinent to include an authoritative statement covering the recent developments in connection with this scheme.

Monteith's discussion has emphasized the importance of the a-c calculating board in the solution of system stability problems. He has also called attention to the part which fault and tower-footing resistances plays in the stability studies. It may be pointed out that while fault resistance is usually a beneficial factor, it is possible for the fault path to be of very high resistance

and to accentuate the problem. It is suggested that in the preparation of future subcommittee reports consideration be given to the inclusion of data on faults and tower-footing resistance as part of the tabulations along the line suggested.

The method of representing the load at the receiving end of a transmission system has a considerable effect on the stability limits as pointed out by Scattergood. The particular method of approximation which he described is of considerable interest.

Scattergood's discussion has called attention to certain corrections to be made in table III of the report. In the same table on pages 278–9 Sels has called attention to the fact that the tabulation should show high tension bussing arrangements at both the sending and receiving ends of all eight lines listed under the Philadelphia Electric Company, Pennsylvania Power and Light Company, and Public Service Electric and Gas Company. If any other errors exist in the table it is quite desirable that attention should be called to them by subsequent written discussions.

# Capacitor Motors With Windings Not in Quadrature

**Discussion and authors' closure of a paper by A. F. Puchstein and T. C. Lloyd published in the November 1935 issue, pages 1235–9, and presented for oral discussion at the induction machinery session of the winter convention, New York, N. Y., January 27, 1936.**

**C. G. Veinott** (Westinghouse Electric & Manufacturing Company, Springfield, Mass.): This paper is an interesting extension of Morrill's paper on the revolving field theory of the capacitor motor. In Morrill's paper, the 2 stator windings are assumed to be displaced by 90 electrical degrees in space; therefore, the voltage induced in one stator winding, by a revolving field set up by the other stator winding, is displaced 90 degrees in time from the voltage induced by its own rotating field. (This displacement may be either forward or backward, as the case may be.) This phase displacement of 90 degrees is taken care of in Morrill's paper by the use of the familiar $j$ operator; it is $+j$ or $-j$; depending upon whether the displacement is forward or backward. The operator $j$ always revolves a vector 90 degrees.

Puchstein and Lloyd use a more generalized operator, namely, a vector operator expressed in exponential form,

$$\epsilon^{j\alpha} \text{ or } \epsilon^{-j\alpha}$$

where $\alpha$ = any angle, expressed in radians.

This vector operator rotates a vector, either forward or backward by the angle $\alpha$. The authors study the case of the capacitor motor where the windings are displaced by an angle, say $\alpha$, and the more generalized operator just given is used to take care of the angular time phase displacement of $\alpha$, occurring between the voltage induced in a winding by its own field and the voltage induced by the field of the other winding. The 2 generalized vector operators above, of course, have to be reduced to the slightly more familiar forms

$$\epsilon^{j\alpha} = \cos\alpha + j\sin\alpha$$

$$\epsilon^{-j\alpha} = \cos\alpha - j\sin\alpha$$

before they become usable in practical equations.

The new idea of this paper is the introduction of this general vector operator into Morrill's equations, which are then reworked, just as Morrill originally worked them; but with the different operator. This idea is the principal contribution of the paper. The authors are to be highly commended, however, for their working out quantitatively of a practical example showing the effect of using winding displaced by angle other than 90 degrees by comparing the performance with a conventional 90 degrees motor. Would that more AIEE authors followed this example!

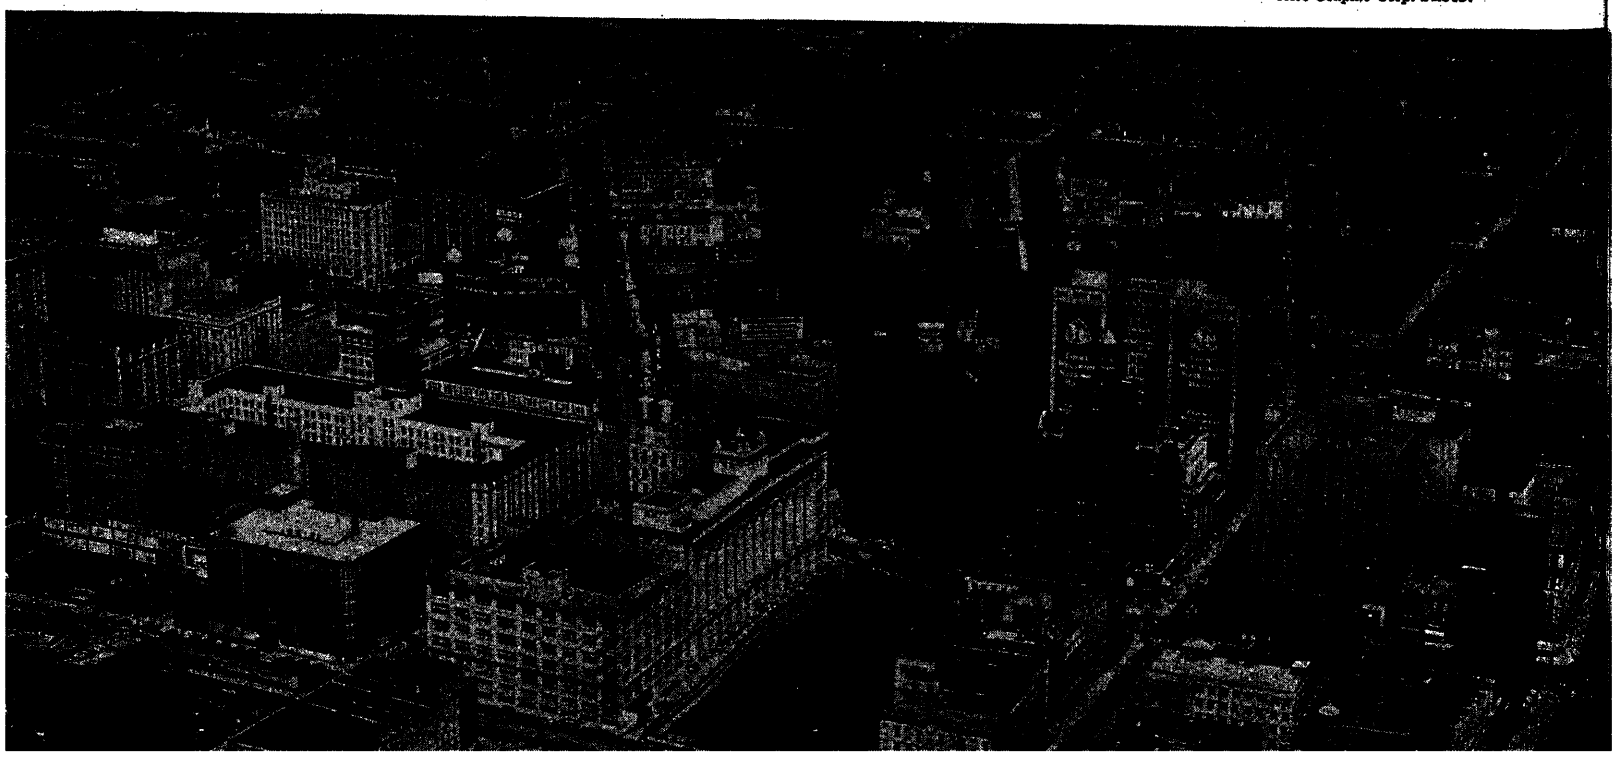
The use of vector operators other than $j$ is not new.

Fortescue uses a 120 degree operator or

$$\pm a = -\frac{1}{2} \pm j\frac{\sqrt{3}}{2}$$

in his classic paper on symmetrical co-ordinates.

Capacitor motors with windings not 90 degrees apart are of little commercial importance. The analysis of this paper is applicable to shaded-pole induction motors with distributed windings, a type which is of some commercial importance. The methods of this paper might also be used to analyze the performance of a 3-phase delta-connected induction motor with one open primary phase. This latter case could likewise be studied by Fortescue's methods.



**A. F. Puchstein and T. C. Lloyd:** We agree in general with the points expressed by Veinott.

He states, however, that $\epsilon^{\pm j\alpha}$ must be put into the form $\cos\alpha \pm j\sin\alpha$ before it becomes usable in practical equations. This of course (although a minor point) depends upon whether the calculation is carried on in rectangular or polar co-ordinates, since $\epsilon^{\pm j\alpha}$ is always equivalent to $1\angle \pm\alpha$.

Material for this paper aside from the reasons given therein, arose from the attempt to obtain torque equations which would be applicable to motors of various types in which the number of slots would not divide properly for 90 degrees displacement of windings. Replacement of the $j$ operator by its more generalized form was not so obviously simple as it appears when dealing with such torque equations. The final value was obtained as the result of an integration covering 24 letter-size pages, although Lyon and Kingsley, by the aid of symmetrical co-ordinates, have given what appears to be a shorter process.

# Institute's 1937 Summer Convention Offers Unusual Vacation Opportunities

THE Institute's annual summer convention, which will be held in Milwaukee, Wis., June 21–25, 1937, with headquarters in the Schroeder Hotel, offers many unique features. Milwaukee, situated on the shore of Lake Michigan, and the State of Wisconsin, with its numerous inland lakes, possess an unusual appeal for all lovers of sports and nature to combine business with vacation. The schedule of events includes the annual business meeting, 10 technical sessions, and 1 general session which is designed to interest a great many members and which is not concurrent with any of the other sessions. The afternoons will be devoted principally to committee meetings, conference sessions, sports, and inspection trips to plants of internationally known manufacturers. Evenings will be devoted to social functions and entertainment.

### Vacation Opportunities

Members of the Institute are urged to consider the opportunities afforded for combining their vacations with the summer convention. Regardless of the kind of of vacation desired—whether it be the social gayety of a smart hotel, the peaceful comfort of a small resort, the rugged sport of a fishing lodge, the restful seclusion of a private cottage, or the good fellowship of tourist camps—all are available near Milwaukee. To the fisherman, Wisconsin offers 7,000 inland lakes and 10,000 miles of trout streams all well-stocked. To lovers of nature there is an abundance of wild life. The northern forests in many places are untouched by man; deer frequently are seen right from the highways. Wisconsin has 160,000 acres in 19 scenic state parks and forests at various points in the state, each possessing its own peculiar and impressive characteristics. To lovers of sports there is almost everything that could be sought, including bathing and swimming in inland lakes or Lake Michigan and Lake Superior, motor boating, sailing, canoeing, golfing and tennis. Members desiring additional information regarding Wisconsin as a vacation land may write to the chairman of publicity, summer convention committee: W. E. Gundlach, 231 West Michigan Street, Milwaukee, or to the Wisconsin Conservation Commission, State Capitol, Madison.

### Friendliness and Hospitality Will Pervade the Inspection Trips

According to the committee, a feature of the inspection trips is that they will be not only interesting and valuable from a technical standpoint, but also outstanding in their personal or social aspects. A spirit of friendliness and hospitality will be exhibited along with production processes, new equipment, and new products: (See special message from summer convention committee elsewhere in this issue.) At least 3

## Schedule of Events

**Monday, June 21**

9:00 a.m.—Registration

10:00 a.m.—Opening Session—Crystal Ball Room

Annual Business Meeting

Annual report of board of directors, in abstract, by H. H. Henline, national secretary

Report of committee of tellers on election of officers

Introduction of and response from president-elect

Presentation of prizes for papers

Presentation of Lamme Medal to Doctor Frank Conrad

President's address by A. M. MacCutcheon

12:45 p.m.—Inspection trip with luncheon at Harnischfeger Corporation, after which the group will divide for a lecture on prefabricated houses or inspection of the National Avenue plant

1:45 p.m.—Inspection trip to Cutler-Hammer, Inc.

2:00 p.m.—Conference of Officers, Delegates, and Members (*a*) Section delegates (*b*) Student Branch counselors

2:30 p.m.—Inspection trip to A. O. Smith Corporation

Evening —Stag Smoker

**Tuesday, June 22**

10:00 a.m.—Power Transmission

General Power Applications

Instruments and Measurements

Education

1:30 p.m.—Inspection trip to Schlitz Brewery—refreshments

2:00 p.m.—Conference of Officers, Delegates, and Members (continued)

Evening —Lecture by Doctor Vannevar Bush

**Wednesday, June 23**

10:00 a.m.—General Session

12:30 p.m.—Inspection trip to Allis-Chalmers Manufacturing Company—luncheon

2:30 p.m.—Conference on Electrical Apparatus for 3-Phase Arc Furnace

Evening —Boat trip on Lake Michigan—dancing, cards, and buffet service on steamer

**Thursday, June 24**

10:00 a.m.—Lightning Protective Equipment and Insulation Co-ordination

Power Generation and Electrical Machinery

Illumination

12:30 p.m.—Directors' luncheon meeting

Afternoon—Inspection trips to:

1. Port Washington Power Plant
2. A. O. Smith Corporation
3. Cutler-Hammer, Inc.

2:30 p.m.—Conference on Field Problems

Evening —President's Reception—dinner and dancing

**Friday, June 25**

10:00 a.m.—Lightning Protective Equipment and Insulation Co-ordination

Vibration and Balance

Communication and Research

Afternoon—Inspection trips to:

1. Globe-Union Manufacturing Company.
2. Allen-Bradley Company
3. A. O. Smith Corporation (if shut down on previous days)

Evening —Farewell gathering at Blue Mound Country Club

Looking north along Lake Michigan and Lincoln Memorial Drive in Milwaukee

of the principal industries already have indicated a desire to provide luncheon for their visitors.

Trips already have been arranged to plants of the following companies: Allis-Chalmers Manufacturing Company, leading manufacturers of all types of heavy electrical equipment, including generators, motors, rectifiers, transformers, and switchgear, and also steam and hydraulic turbines, and tractors; A. O. Smith Corporation, makers of automobile frames, steel pipe, and pressure vessels; Cutler-Hammer, Inc., producers of electrical control and switching equipment; Harnischfeger Corporation, manufacturers of electric cranes and hoisting equipment, electric welders, and more recently a prefabricated steel home of new design; the Port Washington Power Plant of The Milwaukee Electric Railway and Light Company; and the Schlitz Brewing Company.

### Milwaukee's Lake Shore and Harbor Facilities Add Interest

Attendants at the convention will have an opportunity to enjoy the natural scenery and recreational facilities along the beautiful shores of Lake Michigan. Lincoln Memorial Drive leads from downtown Milwaukee north along the lake shore for a distance of 5 miles to Lake Park. It affords a view of the harbor entrance, the Coast Guard station, Milwaukee Yacht Club, fine swimming beaches, Milwaukee Gun Club, and the beautiful treed ravines of Lake Park.

At the north end of the Drive is Milwaukee's new $5,000,000 water purification plant which is rapidly nearing completion. The plant is on 24 acres of made land on the shore of Lake Michigan. It will have a rated capacity of 200,000,000 gallons daily and uses what is known as the rapid sand or mechanical type of filtration. All pumping is by electric drive using a total of 4,000 installed horsepower.

Milwaukee has long been known as one of the important harbor cities of the Great Lakes, receiving and shipping a wide variety of commodities in both foreign and domestic commerce. It is a principal grain shipping port and the foremost coal receiving port on Lake Michigan. More than 4,000 vessels arrive at and clear this port annually. The tonnage in and out over a period of years averages in excess of 7,500,000 net tons annually.

### Future AIEE Meetings

**Summer Convention**
Milwaukee, Wis., June 21–25, 1937

**Pacific Coast Convention**
Spokane, Wash., Aug. 30–Sept. 3, 1937

**Middle Eastern District Meeting**
Akron, Ohio, Oct. 13–15, 1937

**Winter Convention**
New York, N. Y., January 24–28, 1938

**North Eastern District Meeting**
Pittsfield, Mass., Spring 1938

### Post-Convention Trip to the Dells

Many people attending the convention will not want to miss the opportunity of seeing the dells of the Wisconsin River. For this reason special arrangements are being made for a chartered-motor-bus trip to this and other scenic and historical spots on Saturday, June 26, the day following the close of the convention. The trip will include a visit to the dells in the morning, a chicken dinner at Kilbourn, a visit to Devil's Lake and the University of Wisconsin campus in the afternoon and evening dinner at the Hotel Lorraine at Madison, returning to Milwaukee after dinner. The expense of the trip will be very reasonable.

### Technical Sessions

Ten technical sessions have been tentatively scheduled to provide a program of broad scope and current interest. Two sessions will be held on the subject of lightning protective equipment and insulation co-ordination. These sessions are sponsored jointly by the committees on protective devices, power transmission and distribution, and electrical machinery. The subject of insulation co-ordination was first introduced about 1928 and since has been discussed frequently by both operating companies and representatives of electrical manufacturers. Two of the papers report the latest information on the subject as developed by joint committees of the Edison Electric Institute and the National Electrical Manufacturers Association. Two others consist of reports by the lightning arrester subcommittee of the committee on protective devices and the transformer subcommittee of the committee on electrical machinery. The remaining papers are by operating-company engineers.

The subjects for other sessions are as follows: power transmission, general power applications (control), education, power generation and electrical machinery, illumination, vibration and balance, communication and research and instruments and measurements. Those interested in the technique of measurement should find the sessions on insulation co-ordination and vibration and balance also to be of interest. Several papers in the various sessions treat subjects of general interest, such as police radio, industrial economics and business methods, and industrial lighting.

### General Session

Wednesday morning, June 23, has been set aside exclusively for a general session to be held in 2 parts. The first part will consist of an address by Ralph E. Flanders "The Engineer in a Changing World." The second part will consist of discussions by various members of the Institute on the topic: "How Can the Institute Programs Be Made of Greatest Value to the Membership?" (See special announcement elsewhere in this issue.)

A sample of the scenery in the "The Dells" of the Wisconsin River near Kilbourn. A special post-convention trip to this attraction is being arranged

### Rules on Presenting and Discussing Papers

At some of the technical sessions, a few papers may be presented only by title. This will permit the devotion of more time to discussion. At other sessions, papers

# Tentative Technical Program

## Tuesday, June 22

### 10:00 a.m.—Power Transmission

POWER SYSTEM FAULTS TO GROUND—PART I: CHARACTERISTICS, C. L. Gilkeson, Edison Electric Institute, and P. A. Jeanne and J. C. Davenport, Bell Telephone Laboratories, Inc.
April issue, pages 421–8

POWER SYSTEM FAULTS TO GROUND—PART II: FAULT RESISTANCE, C. L. Gilkeson, Edison Electric Institute, and P. A. Jeanne and E. F. Vaage, Bell Telephone Laboratories, Inc.
April issue, pages 428–40

SYSTEM RECOVERY VOLTAGE DETERMINATION BY ANALYTICAL AND A-C. CALCULATING BOARD METHODS, R. D. Evans and A. C. Monteith, Westinghouse Electric & Manufacturing Company.
Scheduled for June issue

NEW OIL-FILLED CABLE LINES IN CHICAGO, Herman Halperin, Commonwealth Edison Company, and G. B. Shanklin, General Electric Company. Scheduled for June issue

### 10:00 a.m.—General Power Applications

A-C MOTOR PROTECTION, C. W. Kuhn, Cutler-Hammer, Inc. May issue, pages 589–93

IMPULSE OPERATION OF MAGNETIC CONTACTORS, Carroll Stansbury, Cutler-Hammer, Inc.
May issue, pages 583–8

COINCIDENTAL ELECTRIC DRIVES, L. E. Miller, Reliance Electric & Engineering Company.
May issue, pages 578–82

### 10:00 a.m.—Instruments and Measurements

A NEW MAGNETIC FLUX METER, G. S. Smith, University of Washington. April issue, pages 441–5

SIXTY-CYCLE CALIBRATION OF THE 50-CENTIMETER UNGROUNDED SPHERE GAP, C. S. Sprague and G. Gold, Purdue University. May issue, pages 594–6

A NEW PHOTOELECTRIC HYSTERESIOGRAPH, R. F. Edgar, General Electric Company.
Scheduled for June issue

A NEW HIGH-SPEED CATHODE-RAY OSCILLOGRAPH, H. P. Kuehni and Simon Ramo, General Electric Company. Scheduled for June issue

### 10:00 a.m.—Education

A SUGGESTED COURSE ON INDUSTRIAL ECONOMICS AND BUSINESS METHODS, R. E. Hellmund, Westinghouse Electric & Manufacturing Company.
April issue, pages 446–54

CURRENT LOCI IN THE GENERAL LINEAR A-C NETWORK, L. A. Hazeltine, Stevens Institute of Technology. March issue, pages 325–30

PER UNIT QUANTITIES, Irven A. Travis, University of Pennsylvania.

FUNDAMENTAL CONCEPTS OF SYNCHRONOUS MACHINE REACTANCES, B. R. Prentice, General Electric Company.

## Wednesday, June 23

### 10:00 a.m.—General Session

1. Address: THE ENGINEER IN A CHANGING WORLD, Ralph E. Flanders, chairman, engineering economics committee, American Engineering Council; President, Jones and Lamson Machine Company, and past-president, ASME.

Intermission

2. Discussion by members of the Institute on HOW CAN THE INSTITUTE PROGRAMS BE MADE OF GREATEST VALUE TO THE MEMBERSHIP?

**In this program, reference to the issue and, in so far as possible, to the page in ELECTRICAL ENGINEERING, is given for all papers.**

### 2:30 p.m.—Conference on Electrical Apparatus for 3-Phase Arc Furnaces

## Thursday, June 24

### 10:00 a.m.—Lightning Protective Equipment

FLASHOVER CHARACTERISTICS OF ROD GAPS AND INSULATORS, subcommittee on correlation of laboratory data of Joint NEMA-EEI Committee on Insulation Co-ordination.
Scheduled for June issue

EXPULSION PROTECTIVE GAPS, W. J. Rudge and E. J. Wade, General Electric Company.
May issue, pages 551–7

DISTRIBUTION LIGHTNING ARRESTER PERFORMANCE DATA, lightning arrester subcommittee of the committee on protective devices.
May issue, pages 576–7

SURGE PROTECTION OF DISTRIBUTION SYSTEMS, J. K. Hodnette and L. R. Ludwig, Westinghouse Electric & Manufacturing Company.

### 10:00 a.m.—Power Generation and Electrical Machinery

SWITCHBOARDS FOR BOULDER POWER PLANT, L. N. McClellan, U. S. Bureau of Reclamation, A. J. A. Peterson, Westinghouse Electric & Manufacturing Company, and C. P. Garman, Bureau of Power and Light, City of Los Angeles.
February issue, pages 224–36

END-CONNECTION REACTANCE OF ELECTRICAL MACHINERY, J. F. H. Douglas, Marquette University. February issue, pages 257–9

END-WINDING LEAKAGE INDUCTANCE OF A SYNCHRONOUS MACHINE, B. H. Caldwell, Jr., General Electric Company. April issue, pages 455–61

CHARACTERISTIC CONSTANTS OF SINGLE-PHASE INDUCTION MOTORS—PART I: AIR-GAP REACTANCES, W. J. Morrill, General Electric Company.
March issue, pages 333–8

## Notice of Annual Meeting

The annual meeting of the American Institute of Electrical Engineers will be held at the Hotel Schroeder, Milwaukee, Wis., at 10 a.m. on Monday, June 21, 1937. This will constitute one session of the annual summer convention which is to be held this year in Milwaukee, Wis.

At this meeting, the annual report of the board of directors, and the reports of the committee of tellers on the ballots cast for the election of officers will be presented.

Such other business, if any, as properly may come before the annual business meeting may be considered.

(Signed) H. H. HENLINE
*National Secretary*

### 10:00 a.m.—Illumination

A NEW APPROACH TO THE INDUSTRIAL LIGHTING PROBLEM; SPECIFIC LIGHTING FOR DIFFERENT SERVICES, H. B. Dates, Case School of Applied Science. May issue, pages 545–50

Address: WHAT A UNIVERSITY HAS DONE TOWARD PROTECTING THE EYESIGHT OF ITS STUDENTS, F. A. Kartak, Marquette University.

FURTHER CHARACTERISTICS OF THE CARBON ARC, W. C. Kalb, National Carbon Company, Inc.
March issue, pages 319–24

Demonstration Address: NEW LIGHT SOURCES, THEIR CHARACTERISTICS AND APPLICATIONS, D. W. Atwater, Westinghouse Lamp Company.

### 2:30 p.m.—Conference on Field Problems

## Friday, June 25

### 10:00 a.m.—Insulation Co-ordination

BASIC IMPULSE INSULATION LEVELS, EEI-NEMA Joint Committee on System Insulation Co-ordination. Scheduled for June issue

INSULATION STRENGTH OF TRANSFORMERS, transformer subcommittee of the committee on electrical machinery. Scheduled for June issue

APPLICATION OF ARRESTERS AND THE SELECTION OF INSULATION LEVELS, J. H. Foote and J. R. North, The Commonwealth & Southern Corporation.
Scheduled for June issue

INSULATION CO-ORDINATION, Philip Sporn and I. W. Gross, American Gas & Electric Company.
Scheduled for June issue

APPLICATION OF SPILL GAPS AND SELECTION OF INSULATION LEVELS, H. L. Melvin and R. E. Pierce, Ebasco Services Incorporated.
Scheduled for June issue

### 10:00 a.m.—Vibration and Balance

DYNAMIC BALANCING OF SMALL GYROSCOPE ROTORS, O. E. Esval and C. A. Frische, Sperry Gyroscope Company, Inc.
Scheduled for June issue

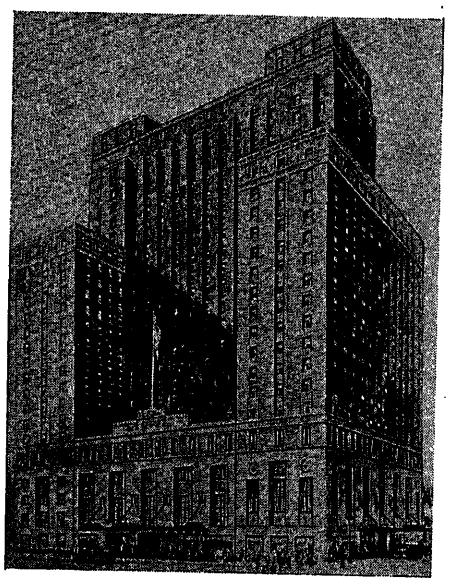
VIBRATION MEASURING INSTRUMENTS: FUNDAMENTAL CONSIDERATIONS IN THEIR DESIGN, C. D. Greentree, General Electric Company.
Scheduled for June issue

THE VIBRATION ISOLATION OF MACHINERY, L. H. Hansel, The Felters Company, Inc.
Scheduled for June issue

PRELIMINARY REPORT ON A PROPOSED TEST CODE FOR APPARATUS NOISE MEASUREMENT, subcommittee on sound of standards committee.

### 10:00 a.m.—Communication and Research

POLICE RADIO COMMUNICATION, E. L. White, Federal Communications Commission, and E. C. Denstaedt, Police Department, Detroit.
May issue, pages 532–44



OXIDATION IN INSULATING OIL, J. B. Whitehead, The Johns Hopkins University, and F. E. Mauritz.
April issue, pages 465–74

PROPERTIES OF SATURANTS FOR PAPER-INSULATED CABLES, G. M. L. Sommerman, American Steel & Wire Company. May issue, pages 566–76

THE DIELECTRIC STRENGTH OF NONINFLAMMABLE SYNTHETIC INSULATING LIQUIDS, P. M. Clark, General Electric Company.
Scheduled for June issue

will be presented in abstract, 10 minutes being allowed for each paper unless otherwise arranged, or the presiding officer meets with the authors preceding the session to arrange the order of presentation and allotment of time for papers and discussion. Authors will be notified officially in each case about one month in advance.

Any member is free to discuss any paper when the meeting is thrown open for general discussion. Usually 5 minutes is allowed to each discusser for the discussion of a single paper or of several papers on the same general subject. When a member signifies his desire to discuss several papers not dealing with the same general subject, he may be permitted a somewhat longer time.

**Hotel Schroeder, Milwaukee, headquarters for the summer convention**

It is preferable that a member who wishes to discuss a paper give his name in advance to the presiding officer of the session at which the paper is to be presented. Each discusser is to step to the front of the room and announce, so that all may hear, his name and professional affiliations. Three typewritten copies of discussion prepared in advance should be left with the presiding officer.

Other discussion to be considered for publication must be submitted, typed double spaced, in triplicate to C. S. Rich, secretary, technical program committee, AIEE headquarters, 33 West 39th St., New York, N. Y., on or before July 9, 1937. Discussion received after this date will not be accepted.

**Principal Hotels in Milwaukee, and Rates**

| Hotel | Single Room | Double Room |
|---|---|---|
| Schroeder | $3.00–4.00 | $6.00–20.00 |
| Wisconsin | 3.00–5.00 | 5.00–10.00 |
| Plankinton | 2.50–4.50 | 4.00–15.00 |
| New Pfister | 2.50–3.00 | 4.00–15.00 |
| Astor | 3.50–5.00 | 4.00– 6.00 |
| Ambassador | 3.00–4.00 | 5.00– 6.00 |
| New Randolph | 2.50–3.50 | 3.50– 6.00 |
| Knickerbocker | 3.00 | 5.00– 6.00 |
| Martin | 2.25–5.00 | |
| Juneau | 2.00–3.00 | 3.00– 5.00 |
| Medford | 1.75–3.00 | 2.75– 5.00 |
| Republican | 1.50–2.50 | 2.50– 4.00 |
| Miller | 1.50–3.00 | 3.00– 5.00 |

## To Summer Conventioners

GEMUTLICHKEIT is the only word to express adequately the spirit which will pervade the coming summer convention in Milwaukee. The entertainments, the hospitality extended to inspection-trip guests, and the sportsmanship displayed on links and courts, will all bear the stamp of *gemutlichkeit.*

One dictionary translation of this word is "quality of good nature," but experts in philology say that no English word, or combination of words, conveys its precise meaning. It is representative of a state of mind which must be lived and felt to be understood; that is, whatever it stands for must be "experienced" to be fully comprehended.

In Milwaukee a committee consisting of more than 60 able and alert men and women is so planning the convention that no one will leave without knowing the meaning of the word "gemutlichkeit." Never again will they have to look in the dictionary or inquire about this word whose meaning is so finely shaded and elusive that it can hardly be expressed with any degree of exactitude in any other language.

However, there are some ways in which you, our guests, can materially assist the committee to accomplish the task to which it has set itself, and I am sure we shall have your hearty cooperation.

(1) The committee will greatly appreciate it if you will make a serious effort to be present at the opening session of the convention. The tenor of a convention is often determined by the spirit which prevails at the first session. If this meeting is well attended and enthusiastically supported, the convention is sure to be a success. Furthermore, this session is the occasion of several impressive ceremonies, such as presentation of prizes and medals.

Above all, the members should keep in mind that the president delivers his annual message to the Institute at the opening session. Always of interest and importance to Institute members, the president's address has special significance when stirring times issue a challenge to professional organizations to take an active part in shaping the destinies of our civilization. No one attending the convention should miss the president's address.

(2) Some of the industries to which inspection trips will be made are planning to serve luncheons to their guests, and it will help them greatly to know as early as possible how many to prepare for. Therefore, register as early as you can for the inspection trips you intend to take.

(3) Elsewhere in this issue is published a list of the principal hotels in Milwaukee. All these hotels are within a 12- to 15-minute ride from convention headquarters (Schroeder). Because of these excellent facilities to please visitors with regard to housing, Milwaukee is a very popular convention city; and in order to avoid last minute congestion, choose your hotel and send in your reservation early. In case you have any difficulty, get in touch with the housing committee and efforts will be made to get you placed to your satisfaction. But do it early.

K. L. Hansen

General Chairman
Summer Convention Committee

### Women's Entertainment

In addition to the regular entertainment the women's entertainment committee is arranging an attractive program for the visiting ladies, which will be announced later.

### Sports

The annual tournaments for both the Mershon golf and tennis trophies will be held as usual, as well as the competition for the Lee golf trophy. The details of the sports program will be announced in a subsequent issue as soon as they have been made available by the sports committee.

### Advance Registration

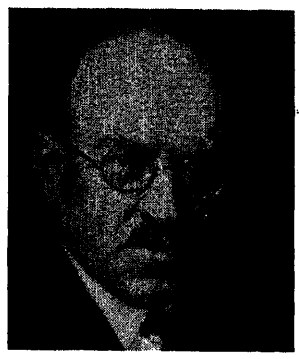
Members who will attend the convention are urged to register in advance by promptly returning the addressed advance-registration card which they will receive by mail. This will be helpful to the committees and permit badges to be made ready in advance, thus avoiding congestion at the registration desk.

A minimum registration fee of $2 will be charged all nonmembers, except Enrolled Students and the immediate families of members.

### Hotel Reservations

All members planning to attend the convention should make their own hotel reservations, and the committee urges that this be done well in advance. A list of the principal hotels in Milwaukee and their rates for

single and double rooms are given in an accompanying tabulation. All are within a 12- to 15-minute ride from convention headquarters (Schroeder). Any one having difficulty in obtaining rooms should contact the housing committee.



COMMITTEE

The personnel of the 1937 summer convention committee is as follows: Otto H. Falk, *honorary chairman;* K. L. Hansen, *chairman;* L. H. Hill, *vice-chairman;* C. H. Krueger, *secretary;* W. E. Crawford, *treasurer;* R. R. Benedict, A. G. Dewars, C. F. Harding, H. S. Osborne, G. G. Post, J. A. Potts, D. L. Smith, and W. H. Timbie. Subcommittee chairmen: J. F. H. Douglas, technical program; E. W. Seeger, finance; L. W. Copeland, entertainment; C. D. Brown, transportation; W. O. Helwig, registration and housing; W. E. Gundlach, publicity; G. F. Crowell, sports; S. H. Mortensen, inspection trips; and Mrs. A. C. Flory, women's entertainment.

## Session on Economics and Institute Activities

A special "general" session on the economic aspects of engineering and Institute activities has been scheduled for Wednesday morning, June 23, during the Institute's 1937 summer convention. The session, which will not be paralleled by any other, has been arranged by the newly appointed special committee on Institute activities, of which H. S. Osborne is chairman. The session will be divided into 2 parts, consisting of: (1) an address "The Engineer in a Changing World," by Doctor Ralph E. Flanders, president of the Jones and Lamson Machine Company, Springfield, Vt.; and (2) a discussion of the topic "How Can Institute Programs Be Made of Greatest Value to the Membership?" by various members of the Institute.

Doctor Flanders has devoted a large amount of time to engineering society activities, having served as president of the American Society of Mechanical Engineers and as member or chairman of many ASME committees. He is a vice-president of American Engineering Council and chairman of its committee on the relation of

Ralph E. Flanders

consumption, production, and distribution; since 1932 he has been active in the public works program of Council. During 1936 he was chairman of Council's committee on engineering economics, and has been a director of the Social Science Research Council. He has written numerous technical papers and 2 books.

Doctor Flanders was born September 28, 1880, at Barnet, Vt., and started his technical career as an apprentice machinist in 1897. In 1903 he became a designer for the International Paper Box Machinery Company, Nashua, N. H., which position he held until 1905, when he became associate editor of *Machinery*, with offices at New York, N. Y. He held that position for 5 years before joining the engineering staff of the Fellows Gear Shaper Company. Springfield, Vt., in 1910. In 1912 Doctor Flanders became director and manager of the Jones and Lamson Machine Company, and has been president of that company since 1933. He has received several honorary degrees.

At the conclusion of Doctor Flanders' address, the meeting will be opened for any questions that those present may wish to ask concerning the subject. Then, after a brief intermission, the second part of the session will begin with brief discussions of various phases of Institute activities by several prominent Institute members, leading up to a general discussion from the floor.

## Membership—

Mr. Institute Member:

The Institute has done much to improve the status of electrical engineering as a profession but much remains to be done. Increased membership will materially aid achievement of one of the aims of the Institute—public recognition of our profession.

Too many of us regard our membership in the Institute as a matter of paying dues. We should attend meetings frequently and take an active part in the affairs of our local Section. We cannot arouse interest in nonmember electrical engineers unless we display interest ourselves.

Let's all take a nonmember guest to our next Section meeting and show him the advantages of membership in the Institute.

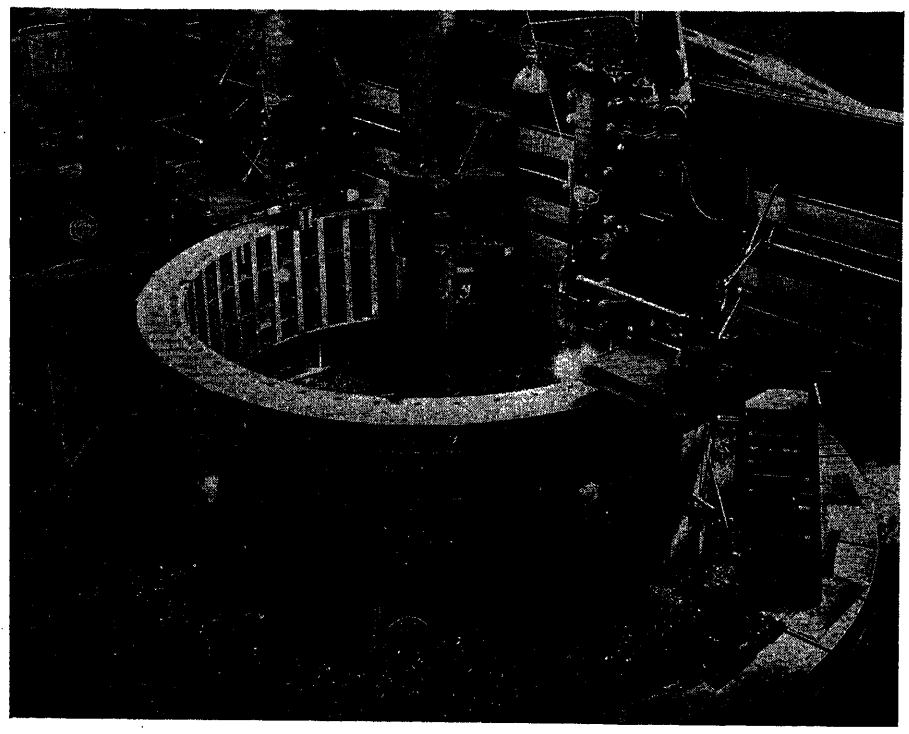
E. T. Gunther

Vice-Chairman, District No. 7
National Membership Committee

## AIEE Executive Committee Meets

A meeting of the executive committee of the American Institute of Electrical Engineers was held at Institute headquarters, New York, N. Y., on March 25, 1937, in place of the regular meeting of the board of directors.

Present: President A. M. MacCutcheon (chairman), F. M. Farmer, W. H. Harrison, Everett S. Lee, and W. I. Slichter, members of the committee; Vice-President A. C. Stevens, and National Secretary H. H. Henline. By standing vote, resolutions were adopted in memory of Junior Past-President E. B. Meyer, who died on January 30, and Past-President and Honorary Member Elihu Thomson, deceased, March 13. (The resolutions were published in the April issue of ELECTRICAL ENGINEERING.)



Reports were presented and approved of meetings of the board of examiners held February 17 and March 17, 1937. Upon the recommendation of the board of examiners, the following actions were taken: 1 applicant was elected to the grade of Fellow; 14 applicants were elected and 19 were transferred to the grade of Member; 96 applicants were elected to the grade of Associate; 106 Students were enrolled.

Monthly expenditures were reported by the finance committee and approved, as follows: February, $27,819.71; March, $17,691.20.

The selection by the District meeting committee of the dates, October 13–15, for the previously authorized 1937 meeting of the Middle Eastern District, at Akron, Ohio, was reported.

Doctor William McClellan was appointed a representative of the Institute upon the Hoover Medal board of award for the six-year term beginning in May 1937, succeeding Doctor F. B. Jewett, whose term expires at that time.

Professor R. W. Warner was appointed a third alternate of the Institute upon the delegatory committee for region V of the committee on engineering schools of the Engineers' Council for Professional De-

**Machining a fabricated-steel stator yoke on a 40-foot boring mill in the plant of the Allis-Chalmers Manufacturing Company, Milwaukee, Wis. An inspection trip to this plant during the forthcoming AIEE summer convention has been scheduled**

velopment, in connection with the accrediting of engineering schools by ECPD.

The executive committee confirmed the appointment, upon nomination by the standards committee, of Doctor Clayton H. Sharp to represent the Institute upon the subcommittee of the United States National Committee of the International Commission on Illumination to consider a proposal of the National Bureau of Standards for the international standardization of photometric units.

Other matters were discussed, reference to which may be found in this or future issues of ELECTRICAL ENGINEERING.

## President MacCutcheon Visits New England Sections

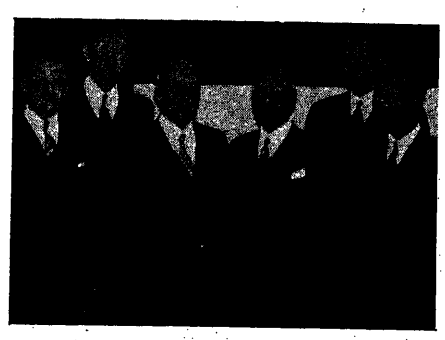
During the week of March 8, 1937, President A. M. MacCutcheon, accompanied by National Secretary H. H. Henline, Vice-President A. C. Stevens, and R. G. Lorraine, secretary of the North Eastern District, visited 5 Sections and one Student Branch of the Institute. This brief report of the tour has been prepared from information supplied by District Secretary Lorraine.

The following meetings were attended by the group:

**New Haven, Conn.** Dinner followed by meeting of Connecticut Section.

**Lynn, Mass.** Meeting of national members of Lynn Section and dinner as guests of the General Electric Company, followed by general Section meeting.

**Boston, Mass.** Dinner followed by Section meeting.



**Providence, R. I.** Luncheon with Providence Section and Brown University Branch followed by joint meeting of Brown University and Rhode Island State College Branches.

**Worcester, Mass.** Dinner followed by joint meeting of Worcester Section and Worcester Polytechnic Institute Branch.

**Springfield, Mass.** Dinner followed by Section meeting.

President MacCutcheon spoke on "The Selection and Training of Electrical Engineers" at the New Haven, Boston, Providence, and Springfield meetings; and on "The Section's Part in Institute Activities" at the Worcester meeting. The dinners preceding the meetings were featured by intimate and informal discussions of Institute policies and procedures. At some of the meetings, in addition to the talks by the president, Vice-President Stevens made short talks on District activities; National Secretary Henline discussed the Sections' records as the national organization sees them, and District Secretary Lorraine discussed the forthcoming District meeting.

In addition to the meetings, the group visited the Cambridge (Mass.) plant of the Simplex Wire and Cable Company, where they were conducted on the inspection trip by officials and other members of the organization; this was followed by a luncheon in the private dining room of the company. At Springfield, Mass., an inspection was made of the Westinghouse plant under the direction of Section Chairman C. G. Veinott and others, and of the United American Bosch plant by officials of that company.

**At the Worcester Section meeting, left to right: District Secretary Lorraine, Professor T. H. Morgan (A'23, M'31) of Worcester Polytechnic Institute, President MacCutcheon, Admiral Ralph Earle, National Secretary Henline, and Vice-President Stevens**

## Baltimore Section Is Host to Student Branch Convention

In 1925, the Philadelphia Section initiated the idea of AIEE Student Branch conventions. Since that time, other Sections in the eastern portion of the Middle Eastern District have joined with the Philadelphia Section in promoting and supporting this successful phase of Institute activities. During the ensuing 12 years, the idea has been widely and effectively adopted by other Sections and Districts.

Monday, April 19, 1937, was Student Branch convention day at The Johns Hopkins University school of engineering, Baltimore, where the thirteenth such meeting of the eastern section of District No. 2 was held, with about 190 students, faculty members, and others interested in attendance. The day's program was full, with a technical session in the morning, a noon luncheon, an afternoon inspection trip, and an evening dinner meeting.

At the technical session, 4 student technical papers were presented:

A LABORATORY POLYPHASE POWER RECTIFIER, T. Chase, Drexel Institute, Philadelphia, Pa.

ELECTRICAL TIME STANDARDS, T. R. Brown, Lehigh University, Bethlehem, Pa.

AN ALGEBRAIC EQUATION SOLVER, D. L. Herr and R. H. Graham, University of Pennsylvania, Philadelphia, Pa.

APPLICATIONS OF A SONIC OSCILLATOR, L. Broomell, Swarthmore College, Swarthmore, Pa.

By decision of a committee of judges, Mr. Brown was awarded a first prize of $10 and Mr. Chase a second prize of $5. Presiding throughout the session was Chairman H. B. Peck of the Johns Hopkins student Branch. Preliminary introductory remarks were made by AIEE Past-President J. B. Whitehead, dean of the school of engineering of Johns Hopkins University, by AIEE President A. M. MacCutcheon, who discussed Institute activities, services, and affairs, by R. L. Thomas, chairman, Baltimore Section, and by National Secretary H. H. Henline.

Those attending the sessions were the guests of the Johns Hopkins Student Branch at luncheon where Dr. Isiah Bowman, president of The Johns Hopkins University, addressed the group on "Flood Control." An afternoon inspection trip to the plant of the Locke Insulator Corporation gave to those attending an opportunity to witness a demonstration of high-voltage insulator testing, and also to observe the

**A group of those that attended the recent Southern District Student Branch conference at Alabama Polytechnic Institute**

manufacture of porcelain insulators by the wet process.

The evening dinner meeting was held jointly by the Johns Hopkins Student Branch and the Baltimore Section in honor of President MacCutcheon, who spoke on "The Selection and Training of Electrical Engineering." Past-President Whitehead and President-Designate Harrison, and others spoke briefly.

With the co-operation of the Baltimore Section, the meeting was jointly participated in by the 8 Student Branches of the eastern section of the Middle Eastern District:

Drexel Institute, Philadelphia, Pa.
The Johns Hopkins University, Baltimore, Md.
Lafayette College, Easton, Pa.
Lehigh University, Bethlehem, Pa.
University of Pennsylvania, Philadelphia, Pa.
Princeton University, Princeton, N. J.
Swarthmore College, Swarthmore, Pa.
Villanova College, Villanova, Pa.

Although having no Student Branches, the University of Delaware and Haverford College both contributed support. Visiting Branches also participating in the meeting were:

Catholic University of America, Washington, D. C.
George Washington University, Washington, D. C.
University of Maryland, College Park, Md.

A generous delegation of students and faculty was present representing each of the Branches.

Plans already decided upon provide for similar meetings at Lehigh University in 1938, and at Drexel Institute in 1939.

## 1937 AIEE Year Book Is Now Available

In accordance with the provisions of the Institute's 1936–37 budget as approved by the finance committee and the board of directors, the 1937 edition of the AIEE Year Book has been issued, in limited edition, and is available to members of the Institute who have use for it. The book contains essentially the same material as was included in the 1936 edition; business and mailing addresses have been corrected as of February 27, 1937.

In keeping with established custom, copies of the Year Book have been distributed to all national, District, and Section officers, to Student Branch counselors, and to all members of all national committees. Other members wishing to secure a copy may do so by writing to the AIEE order department, 33 West 39th Street, New York, N. Y., giving correct mailing addresses.

The Year Book is not available to nonmembers of the Institute, nor is its use permitted for commercial, promotional, or other circularization purposes.

## Student Conference Held at Alabama Polytechnic

Some 140 of the South's top-ranking students in electrical engineering, and Student Branch counselors from 15 colleges and universities registered at the annual student conference of the AIEE Southern District, held April 1–3 at Alabama Polytechnic Institute, Auburn. All principal features of the program were confined to Friday, April 2, with Thursday afternoon given over to registration followed by an informal smoker in the evening, and Saturday devoted to inspection trips to Tuskegee Institute and to hydroelectric plants of the Alabama Power Company on the Coosa River.

For the first time since the initiation of the Student Branch conferences in the Southern District, every Branch in the District was represented:

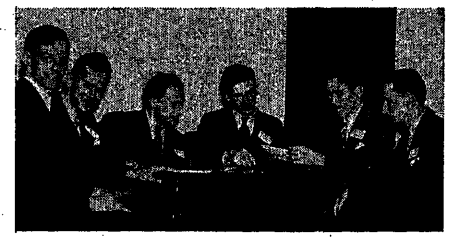
Alabama Polytechnic Institute, Auburn, Ala.
University of Alabama, University, Ala.
Clemson Agricultural College, Clemson, S. C.
Duke University, Durham, N. C.
University of Florida, Gainesville, Fla.
Georgia School of Technology, Atlanta, Ga.
University of Kentucky, Lexington, Ky.
Louisiana State University, Baton Rouge, La.
University of Louisville, Louisville, Ky.
Mississippi State College, State College, Miss.
North Carolina State College, Raleigh, N. C.
University of North Carolina, Chapel Hill, N. C.
University of South Carolina, Columbia, S. C.
University of Tennessee, Knoxville, Tenn.
Tulane University, New Orleans, La.
Virginia Military Institute, Lexington, Va.
Virginia Polytechnic Institute, Blacksburg, Va.
University of Virginia, University, Va.

Six technical papers were presented at the Friday morning technical session:

ELIMINATION OF MAN-MADE STATIC, Gordon Rogers, Clemson College, Clemson College, S. C.

A TREATISE ON RURAL ELECTRIFICATION, J. E. Lowery, Alabama Polytechnic Institute, Auburn, Ala.

TESTING VACUUM TUBES, T. M. Ferril, Jr., Mississippi State College, State College, Miss.



HIGH FREQUENCY RADIO TRANSMITTERS, Wayne Mason, University of Florida, Gainesville, Fla.

AN ELECTRICAL NURSE, J. A. Potter, Georgia School of Technology, Atlanta, Ga.

NOTES ON A SERIES SCHEME OF MODULATION, C. W. Harrison, Jr., University of Virginia, University Va. (Presented by Mr. Porter of University of Virginia.)

At the elaborate banquet held Friday evening, a first prize for the best technical paper was presented to Mr. Mason, with second and third honors conferred, respectively, upon Mr. Potter and Mr. Rogers. The presentation of prizes was made by Professor W. W. Hill, counselor of the Student Branch at Alabama Polytechnic Institute and chairman of the District committee on student activities. Professor Hill carried the principal responsibilities of the conference, ably assisted by L. C. Balch, chairman of the API Student Branch.

Principal speaker at the banquet was National Secretary H. H. Henline. The gist of his address was to the effect that engineering, instead of having in the near future a decadent place in modern civilization, will have an increasingly important place and opportunity to function in the world's development. He stressed the need for engineers of the future to have a greater knowledge of economics and a better understanding of social problems. Mark Eldredge, AIEE vice-president for the Southern District, also spoke briefly as did some others including API President L. N.

**The student authors of papers presented at the Southern District Student Branch conference**

(Left to right) James A. Potter (2d prize) Georgia Tech; T. M. Ferrill, Jr., Mississippi State; G. J. Porter, Virginia; Gordon Rogers (3d prize) Clemson; John E. Lowery, Alabama Poly.; Wayne Mason (1st prize) Florida

Duncan. The toastmaster was Professor John C. McKinnon of the API mechanical engineering faculty. Following the banquet an engineers' ball was held for visitors and API engineering students at the college's newly constructed WPA Hall.

At a short official business session Friday afternoon, Virginia Military Institute was selected as the location for the next annual District Student Branch conference. Colonel S. W. Anderson, professor of electrical engineering at VMI and counselor of its Student Branch, accordingly was elected chairman of the District committee on student activities and designated so to represent the Fourth District at the forthcoming summer convention. An extended discussion among counselors and students led to a decision to restrict to 20 minutes the time allowed for the presentation of technical papers, but to allow unlimited time for discussion of them. The papers committee decided to give preference to papers based upon original investigations.

## Chicago Section Sponsors Joint Meeting on Economics

At a joint meeting on March 22, 1937, the Chicago Section of the AIEE and the Western Society of Engineers heard 2 papers on "A Broader Field of Action for the Engineers." In the first, P. B. Juhnke (M'20, F'36) discussed the position of the engineers in the general economic structure of the nation and urged that they become better acquainted with questions involving the production and consumption of goods and the effect of changes in the monetary system. The second paper, presented by F. R. Innes (A'25, M'26) western editor of *Electrical World*, discussed the part that the engineer can take in directing the activities of the government in the electric-power field.

Some 200 members and guests of the participating bodies attended the meeting. According to Earle Wild (A'27, M'36) chairman of the publicity committee of the Chicago Section, those present expressed themselves as being highly in favor of meetings of this type. Further, it was the reported consensus of opinion that engineering societies in general should take more effective action concerning public affairs and broad economic problems within their respective fields.

**ASTM Standards Index.** An index to the standards and tentative standards of the American Society for Testing Materials which gives information as of January 1, 1937, has been made available. Copies are furnished without charge on request to ASTM headquarters, 260 South Broad St., Philadelphia, Pa.

**Willard Gibbs Medal Awarded.** Doctor Herbert Newby McCoy, internationally known for his achievements in radioactivity and in many other fields of chemical science, has been awarded the 1937 Willard Gibbs Medal of the Chicago (Ill.) section of the American Chemical Society. Doctor McCoy, for 16 years a member of the faculty of the University of Chicago and now vice-president and director of research of the Lindsay Light and Chemical Company, Chicago, was cited as "pioneer in a greater number of fundamental discoveries than any but 3 or 4 living American chemists." The medal was founded in 1911, and is awarded by a national jury of scientists.

## High-Voltage Conference to Be Held in Paris

The ninth session of the International Conference on High Voltage Electric Systems (CIGRE) is scheduled to be held in Paris, France, from June 24 to July 2, 1937. This permanent organization of CIGRE was created in 1921 under the auspices of the International Electrotechnical Commission, and its biennial sessions bring together delegations from 40 different countries for the discussion of all problems relating to the design, construction, and operation of high-voltage electric systems. The last session in 1935 was attended by more than 1,200 delegates including government officials, power-utility engineers and executives, electrical manufacturers, and university professors interested in high-voltage developments.

At the June session in Paris, 112 technical papers from 20 different countries are already scheduled to be presented, including the following 6 American papers:

1. HIGH-SPEED CLEARING AND ULTRA-HIGH-SPEED RECLOSING OF FAULTED HIGH-VOLTAGE TRANSMISSION LINES, by Philip Sporn (A'20, F'30) American Gas and Electric Company, New York, N. Y., and D. C. Prince (A'16, F'26) General Electric Company, Philadelphia, Pa.

2. LIGHTNING CURRENTS ON TRANSMISSION LINES, by W. W. Lewis (A'09, M'13) General Electric Company, Schenectady, N. Y.

3. LIGHTNING-STROKE TESTS ON HIGH-VOLTAGE APPARATUS IN THE LABORATORY, by P. L. Bellaschi (A'29, M'34) Westinghouse Electric and Manufacturing Company, Sharon, Pa.

4. LIGHTNING-PROOF TRANSMISSION LINES, by A. F. Bang (A'11) and Edwin Hansson (A'19, M'35) both of the Pennsylvania Water and Power Company, Baltimore, Md.

5. INVESTIGATION BY PRECISE MEASUREMENTS OF SUSPENSION-INSULATOR DESIGN CHARACTERISTICS FROM THE STANDPOINT OF SERVICE REQUIREMENTS, by L. A. Meisse and J. J. Taylor, both of the Ohio Brass Company, Barberton.

6. INSULATING OILS, by K. S. Wyatt (A'32) The Detroit (Mich.) Edison Company.

The proceedings are conducted in English, French, and German, and advance copies of all papers are available to all registered delegates. All delegates and their families are accorded reductions of 50 per cent in railway fares, and 40 per cent in hotel rates in France, and visits have been arranged for the delegates to the Paris International Exposition and to interesting electrical installations as well as to points of historical and scenic interest.

A permanent United States national committee has been formed, composed of Frederic Attwood (M'27), F. A. Allner (A'12 M'14), P. L. Bellaschi (A'29, M'34), W. W. Lewis (A'09, M'13), E. L. Moreland (A'11, F'21), Philip Sporn (A'20, F'30), and a large American delegation is expected to attend the June session in Paris. Further information may be obtained from CIGRE Headquarters, 54 Avenue Marceau, Paris, or from the president of the United States national committee, Frederic Attwood, 30 Church Street, New York, N. Y.

**Perkin Medal for 1937 Presented.** Thomas Midgley, Jr., vice-president of the Ethyl Gasoline Corporation, was presented with the Perkin Medal for 1937 of the Society of Chemical Industry at a joint meeting of the society and the American Chemical Society held on January 8, 1937. The medal is awarded annually for the most valuable work in applied chemistry and was presented to Mr. Midgley in recognition of his work in the development of antiknock motor fuels and safe refrigerants. Mr. Midgley is a fellow of the American Association for the Advancement of Science, and a member of the American Chemical Society, American Institute of Chemical Engineers, Society of Automotive Engineers, and other organizations.

## Joint Summer Session on Economics Planned

The seventh annual economics conference for engineers will be held at Stevens Institute of Technology camp, Johnsonburg, N. J., June 18–26, 1937, concurrently with a summer session sponsored by the Society for the Promotion of Engineering Education on the study of economics in engineering colleges. Members of the conference will be welcome at any of the lectures arranged for the SPEE session. A series of evening lectures by leading authorities on economic and industrial topics has been arranged for both groups. The 4 courses planned are:

1. INDUSTRIAL MANAGEMENT, conducted by Professor George W. Barnwell of Stevens Institute of Technology.

2. COURSE CONTENT AND TEACHING METHODS organized by Professor W. D. Ennis of Stevens Institute of Technology and conducted by several lecturers.

3. INDUSTRIAL ECONOMICS, conducted by Doctor Dexter S. Kimball, formerly dean of engineering, Cornell University, and Professor W. D. Ennis of Stevens Institute of Technology.

4. INDUSTRIAL PSYCHOLOGY, conducted by Doctor R. W. Uhrbrock, head of research department, industrial relations division, The Procter & Gamble Company.

Correspondence on enrollment should be addressed to President Harvey N. Davis, Stevens Institute of Technology, Hoboken, N. J.

**Semiannual Meeting of ASME.** The American Society of Mechanical Engineers will hold its semiannual meeting at Detroit, Mich., May 17–21, 1937. The meeting will stress the contribution of the automotive industry to industry in general, al-

though power plant engineering and other subjects will be included. The use of the Diesel engine will be discussed in several railroad sessions. Inspection trips to points of interest in the vicinity of Detroit have been arranged and include the River Rouge plant of the Ford Motor Company, Connors Creek station of The Detroit Edison Company, and the continuous strip mill of the Great Lakes Steel Corporation.

## Triennial Montefiore Prize Award Now Open

Constituting interest on 150,000 Belgian francs, distributed triennially in international competition for the best original work presented on scientific advancement and progress in technical application of electricity in every field, the George Montefiore Foundation prize award now is open again to candidates. The amount available for 1938 is 18,000 francs (about $600); the closing date for entries is April 30, 1938.

The competition is limited to works presented during the 3 years that immediately precede the meeting of the jury of award. Papers either signed or anonymous are acceptable in typewritten manuscript or printed form, and must be written in either French or English and submitted in duplicate. By a $^4/_5$ vote of the jury of award, composed of 5 Belgian and 5 other electrical engineers, $^1/_3$ of the available amount may be awarded to a person who has not taken part in the competition, or to a work which without completely fitting the program, discloses a new idea that may have important developments in the electrical field.

The secretary-registrar of the foundation may be addressed at the headquarters of the Association des Ingénieurs Électriciens, 31 Rue Saint-Gilles, Liege, Belgium.

**TVA Report.** The annual report of the Tennessee Valley Authority for the fiscal year ended June 30, 1936, has been printed as a 377-page paper-bound volume, and may be obtained from the Superintendent of Documents, Washington, D. C., at 55 cents per copy.

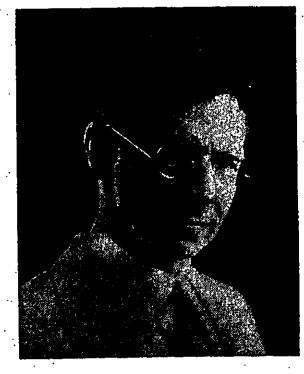
## Niagara Hudson Companies Consolidate

The Buffalo General Electric Company, the Niagara Electric Service Corporation, and the Tonawanda Power Company have filed a certificate of consolidation with the department of state at Albany, N. Y., following receipt of an order of the public service commission approving the consolidation of these companies as the Buffalo Niagara Electric Corporation. The announcement by Colonel William Kelly, (F'25) president of the Buffalo Niagara & Eastern Power Corporation, parent company for the 3 operating units involved in the consolidation, points out that the move is a further step in the simplification of the corporate structure of the Niagara Hudson power system, and reduces the number of system companies to 33 from a total of 59 in existence on December 31, 1929, the year the Niagara Hudson Power Corporation was formed.

The Buffalo General Electric Company was incorporated in 1892 from a consolidation of 2 smaller companies, and in 1915 absorbed a third company. Under another name, Niagara Electric Service Corporation also was formed in 1892, and adopted its present name in 1915; in 1928 2 smaller companies were acquired. The Tonawanda Power Company was incorporated in 1899 as a consolidation of 2 companies. Together these companies serve over 700,000 people.

## Pennsylvania Railroad Continues Electrification

The Pennsylvania Railroad has awarded contracts to 5 companies for continuation of electrification work. The chief lines now to be electrified are the main line from Paoli, near Philadelphia, to Harrisburg, Pa.; the freight line from Morrisville, Pa., near Trenton, N. J., to Harrisburg; the freight line from Columbia, Pa., to Perryville, Md.; and the freight line from Monmouth Juction to South Amboy, N. J. This will mark the completion of the original electrification program on the eastern lines as announced by the railroad in 1928. The work will be financed by a $52,670,700 bond issue, and is expected to be completed in 18 months.



The new work will involve electrification of 315 miles of line and 773 miles of track. Upon completion of the work, the Pennsylvania Railroad system will have 2,677 miles of electrified trackage. The new construction work will be of the same type as that now employed elsewhere in the railroad's eastern electrified territory. It is known as the cross-catenary construction, based on a system of overhead conductors held in place by an arrangement of flexible wires supported between structural steel poles set in concrete beds beyond the outer edges of the track.

The 4-track main line of the Pennsylvania is now electrified between New York, Trenton, Philadelphia, Wilmington, Baltimore, and Washington, as are also the commutation lines around Philadelphia and New York.

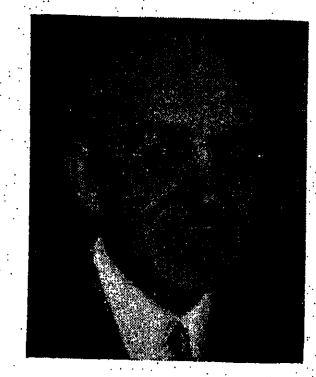
**Annual Convention of American Transit Association.** The 56th annual convention of the American Transit Association and its affiliates will be held September 19–23, 1937, at White Sulphur Springs, W. Va. The convention is expected to bring together executives, operators, and mechanical men representing more than 90 per cent of the transit operations in the United States, Canada, and Mexico. Representatives of manufacturing companies also will attend.

# Personal Items

W. D. Coolidge (A'10, M'34, Edison Medalist '27) director of the research laboratories of the General Electric Company, Schenectady, N. Y., recently was awarded a John Scott Medal "for the application of a new principle in X-ray tubes," as announced in the April 1937 issue of Electrical Engineering, pages 495-6. Doctor Coolidge was born October 23, 1873, at Hudson, Mass., and received the degrees of bachelor of science in electrical engineering (1896) and doctor of philosophy (1899) at Massachusetts Institute of Technology and the University of Leipzig (Germany), respectively. Following his graduation in 1899 he was appointed to the faculty of Massachusetts Institute of Technology in 1901, as an instructor in physical chemistry. In 1904 he was promoted to assistant professor of physicochemical research, but served in that capacity for only one year before joining the staff of the General Electric research laboratories at Schenectady. From 1908 until 1927 Doctor Coolidge served as assistant director of the research laboratories, and in 1928 was made associate director. He has been director of the laboratories since 1932. He has been active in many branches of electrical research, but is most widely known for his development of a process for manufacturing ductile tungsten for use in incandescent lamps, for the Coolidge X-ray tube, for improvements in submarine detecting devices, and

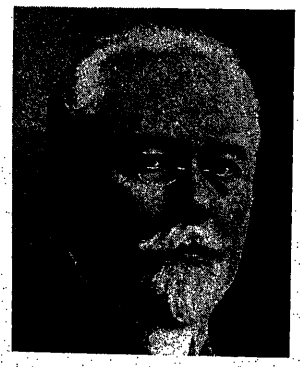
W. D. COOLIDGE

for researches on cathode-ray tubes. Doctor Coolidge received the Edison Medal in 1927 "for his contributions to the incandescent electric lighting and the X-ray arts." He has been honored by several



other scientific organizations, having received the Rumford Medal in 1914 "for invention and applications of ductile tungsten," the Howard N. Potts Medal "for development of a new and improved X-ray tube," the Louis Edward Levy Medal of the Franklin Institute, the gold medal of the American College of Radiology, a medal of award at the Panama-Pacific International Exposition in 1915, the Hughes Medal of the Royal Society in 1927, and the Washington Award in 1932. Doctor Coolidge served the Institute as a member of the committee on electrophysics from 1927 to 1929. He has contributed the results of his original researches to many scientific publications, and has presented several papers before the Institute. Doctor Coolidge is a member and past-vice-president of the Washington Academy of Sciences, and honorary member of the American Roentgen Ray Society, a fellow of the American Academy of Arts and Sciences, and a member of the American Chemical Society, American Electrochemical Society, American Physical Society, National Academy of Sciences, American Association for the Advancement of Science, Radiological Society of North America, American College of Radiology, and several foreign scientific societies. He was a member of the Corporation of Massachusetts Institute of Technology from 1930 to 1935.

R. H. TAPSCOTT (A'18, F'29, past vice-president) who has been vice-president in charge of electrical operations, Consolidated Edison Company of New York (N. Y.), Inc., recently was elected president and a trustee of that company. Mr. Tapscott was born in Brooklyn, N. Y., August 31, 1885 and was graduated from Union College with the degree of bachelor of science in electrical engineering in 1909, following which he joined the testing department of the General Electric Company, Schenectady, N. Y. Shortly afterward he was transferred to the lighting engineering department, where his work largely involved co-operation with a group of New York utility companies. In 1917 Mr. Tapscott left the General Electric Company to become assistant chief electrical engineer of the New York Edison Company. In 1925 he was promoted to the position of electrical engineer, and in 1932 became vice-president of that company and of the United Electric Light and Power Company. In 1936 he was elected vice-president of the Consolidated Edison Company of New York when the New York Edison Company, Inc., was merged with the Consolidated Edison Company. For the last 5 years Mr. Tapscott has been co-ordinating the engineering, construction, and operation of the electric companies affiliated with the Consolidated Edison Company. He served the Institute as a director (1930-34) and as a vice-president (1934-36); in addition, he has been a member of the committees on standards, 1924-29; electrical machinery, 1926-27; power transmission and distribution, 1926-28; headquarters, 1928-36 (chairman, 1929-33); Edison Medal, 1930-34; finance, 1931-36 (chairman, 1934-36); and co-ordination of Institute activities, 1934-36. Mr. Tapscott was active in the former National Electric Light Association. He was chairman of the electrical apparatus committee, and later a member of the engineering national committee of that organization.



ANDRÉ BLONDEL (A'05, HM'12) professor of applied electricity at l'Ecole Nationale des Ponts et Chaussees, Paris, France, has been awarded the Faraday Medal of the British Institution of Electrical Engineers. The medal is awarded once each year for notable scientific or industrial advancement in electrical engineering, or for conspicuous service rendered to the advancement of electrical science. Professor Blondel was born at Chaumont, France, in 1863, and was graduated from the universities of Paris and Dijon in 1889. He was then appointed engineer in the Department des Ponts et Chaussees (civil engineering), and from 1890 to 1927 was engaged in the lighthouse service of that department, with the titles of engineer-in-chief and inspector-general. He has held his present position as professor of applied electricity since 1904. During his long service, Professor Blondel has been instrumental in introducing many important changes in signaling on the coasts of France, principally by means of radio. In 1897 he conducted an exhaustive series of experiments on the electric arc, which led him to study the measurement of electrical quantities and to develop the art of photometry, a field in which he has long been a leading authority. His investigations have been extended to include the advancement of electrical theory and practice in relation to many types of equipment. He is perhaps most famous for his 2-reaction theory of synchronous machines and his work on the oscillograph, although he has to his credit many inventions in widely diversified electrical applications. His published contributions to electrical-engineering literature have been extensive. He has presided over committees and commissions, national and international, and has received many honors in his own land and abroad.

R. A. MILLIKAN (M'22, HM'33, Edison Medalist '22) director of the Norman Bridge Laboratory of Physics and chairman of the executive council of California Institute of Technology, Pasadena, has been awarded a 1937 Franklin Medal of the Franklin Institute "for his isolation and measurement of the fundamental unit of electricity, the electron." Doctor Millikan was born at Morrison, Ill., March 22, 1868, and received the degree of bachelor of arts at Oberlin College in 1891; in 1895 he received the degree of doctor of philosophy at Columbia University, and during the following year attended the universities of Berlin and Göttingen. He has received honorary degrees from universities in the United States and other countries. From 1891 to 1893 Doctor Millikan tutored in physics at Oberlin College, and in 1896 became an assistant in physics at the University of Chicago, becoming assistant professor in 1902. In 1906 he became associate professor and continued to serve in that capacity until he was appointed professor in 1910. Since 1921 he has been director of the Norman Bridge Laboratory of Physics and chairman of the executive council of California Institute of Technology. Doctor Millikan has conducted many fundamental experiments in physics that have become important contributions to scientific knowledge. Recently he has been active in researches pertaining to the so-called cosmic ray and to the physics of the electron, although many of his earlier investigations were more directly applicable to electrical engineering. Doctor Millikan is a member of many technical and scientific societies in the United States and in foreign countries, and has served as president of several of them.

H. A. WINNE (A'16) manager of sales in the mining and steel mill section of the industrial department, General Electric Company, Schenectady, N. Y., has joined the engineering department of that company as general assistant to the vice-president in charge of engineering. Mr. Winne, a native (1888) of Cherry Valley, N. Y., attended Syracuse University, graduating in 1910 with the degree of electrical engineer. In the same year he entered the employ of the General Electric Company as a student engineer in the testing department. In 1911 he became head of the large motor, generator, and synchronous converter test, and in the following year was made assistant general night foreman of the testing department. In 1916 Mr. Winne was promoted to the power and mining engineering department, where he remained until 1922, when he was transferred to the steel

R. A. MILLIKAN

mill section of the industrial engineering department. He became head of the steel mill section in 1930, and in 1936 was appointed manager of sales of the combined mining and steel mill sections. Mr. Winne is a member of the Institute's committees on electric welding and applications to iron and steel production.

E. V. CATON (M'23) chief engineer and manager of power production, Winnipeg (Man., Canada) Electric Company, has been elected president of the Association of Professional Engineers of Manitoba. Mr. Caton, a native (1884) of Hore, England, attended Brighton Technical College and Sheffield University, and received an honors certificate from the City of Guilds Institute in Electrical Engineers. He received his early technical training in various English firms before going to Canada in 1912 to accept a position as chief engineer of the Hydro Electric System of the City of Winnipeg, with full charge of extensions and construction. In 1922 he became electrical engineer for the Winnipeg Electric Company and has been manager of that company since 1925.

C. H. SHARP (A'02, F'12, member for life) consulting engineer, White Plains, N. Y., has been appointed to represent the Institute upon the subcommittee of the United States National Committee of the International Commission on Illumination to consider a proposal of the National Bureau of Standards for the international standardization of photometric units. Doctor Sharp is a member of the Institute's committee on standards and of the Thomas Alva Edison Foundation.

W. S. GORDON, Jr. (A'27, M'35) has resigned as superintendent of electrical construction at the Philadelphia, (Pa.) Navy Yard to accept a position as supervising engineer with Vare Brothers, Philadelphia, in connection with that firm's portion of the Harrisburg electrification of the Pennsylvania Railroad. Mr. Gordon is co-author of a paper "A Review of European Railway Electrification," published in the April 1932 issue of ELECTRICAL ENGINEERING, pages 244-52.

WILLIAM MCCLELLAN (A'04, F'12, past-president) president of the Potomac Electric Power Company and the Washington (D. C.) Railway and Electric Company, has been appointed a representative of the Institute upon the Hoover Medal board of award for the 6-year term beginning in May 1937. Doctor McClellan is also the Institute's representative on the council of the American Engineering Council.

A. A. THOMPSON (A'08) Downers Grove, Ill., an employee of the General Electric Company, has received a 1936 Charles A. Coffin Foundation award "in recognition of his unusual keenness in seeing trouble and his persistence in correcting it." Mr. Thompson has been associated with the General Electric Company since 1905.

R. W. WARNER (M'28) professor of electrical engineering, University of Kansas, Lawrence, has been appointed a third alternate upon the delegatory committee for region 5 of the committee on engineering schools of the Engineers' Council for Professional Development, relative to the accrediting of engineering schools by the Council.

T. O. SWEATT (A'33) recently resigned from the electrical department of Gibbs & Cox, Inc., marine architects and engineers, New York, N. Y., to accept a position with the consulting engineering firm of Gibbs & Hill, Inc., New York.

E. C. BROWN (A'26) assistant manager, Connecticut Valley Power Exchange, Hartford, Conn., recently was elected chairman of the New England System Operators' Club.

H. A. WAGNER (A'98, M'03) president of the Consolidated Gas, Electric Light, and Power Company of Baltimore, Md., has been elected a member of the executive committee of the Baltimore Association of Commerce.

H. C. HAMILTON (A'23, M'26) superintendent of the standardizing and testing department of the Edison Electric Illuminating Company of Boston, Mass., has been elected chairman of the New England Electrical Equipment Committee.

# Obituary

EDGAR KNOWLTON (A'11) electrical engineer, General Electric Company, Schenectady, N. Y., died January 19, 1937. Mr. Knowlton was born July 7, 1871, at Portland, Me., and received his formal engineering education through correspondence schools and independent study. He entered the employ of the General Electric Company in 1893 as a draftsman on a-c motor and generator design, and was continuously associated with that company for almost 44 years. In 1899 Mr. Knowlton was transferred to the a-c engineering department on preliminary mechanical and electrical design of a-c machinery, and in 1903 was transferred to the design of turboalternators. Later he was placed in charge of turbogenerator design, and for many years was engaged in a-c engineering problems.

JAMES DHU ANDREW (A'06) manager of The American Boiler Manufacturers Association, New York, N. Y., died March 22, 1937. Mr. Andrew was born October 29, 1874, at Brooklyn, N. Y., attended the school of mines of Columbia University and in 1899 became a mechanical engineer for the Metropolitan Street Railway Company of New York, N. Y. From 1903 to 1906 Mr. Andrew was chief engineer for the New York Edison Company. For 6 years thereafter he was superintendent of power for the Boston (Mass.) Elevated Railway Company, following which he was superintendent of engineering for the Edison Electric Illuminating Company of Boston. Later he was manager of ship construction of the Hog Island Shipyard, president of the American Balsa and Balsa Refrigerator Company, New York, and president of the Standard Tank Car Company, Sharon, Pa. He served also as vice-president of Stevens and Wood, Inc., of New York, in charge of design, construction, and operation of some power plants in Ohio. From 1926 to 1929 Mr. Andrew was a general consulting engineer for Armour & Company, Chicago, Ill. Later he was chief engineer of the Niagara Hudson Power Corporation. He was a member of The American Society of Mechanical Engineers and the Society of Naval Architects and Marine Engineers.

FREDERICK STEWART CUTTING (M'31) deputy public service engineer of the City of Providence, R. I., died March 13, 1937. Mr. Cutting was born January 18, 1882, at Cranston, R. I. In 1904 he became assistant to the president of the Massie Wireless Telegraph Company, Providence, and was placed in charge of design, construction, testing, and maintenance. He remained in the employ of that company until 1912, when he was engaged as an electrician for the New London (Conn.) Ship and Engine Company. In the following year he became chief clerk of the power and line department of The Rhode Island Company, which later became the United Electric Railways Company. During the World War, and until 1923, Mr. Cutting served in the United States Navy, first as an instructor in electrical engineering at the United States Naval Radio School at Harvard University, and later as an engineering officer and inspector of machinery. From 1923 to 1926 he was employed in electrical construction work for the Dwight P. Robinson Company and the Carleton-Mace Company, of Boston, Mass., and for a brief period was employed as appraisal engineer for Jackson and Moreland, consulting engineers. In 1927 Mr. Cutting was appointed deputy smoke inspector for the City of Providence; in 1929, deputy public service engineer. He was a member of The American Society of Mechanical Engineers.

FRANK GEORGE MCRAE (A'07) New York Power and Light Corporation, Albany, N. Y., died January 24, 1937. Mr. McRae was born February 5, 1879, at Schuylerville, N. Y., and was graduated from Cornell University with a degree in electrical engineering in 1902. In 1903 he entered the employ of the Hudson River Electric Power Corporation, Albany, where he served in various capacities in the operating department of that company until 1914. At that time he became superintendent of distribution of the Adirondack Electric Power Corporation at Glen Falls, N. Y. In 1922 Mr. McRae was transferred to the Amsterdam (N. Y.) offices of that company and in the following year to the Schenectady offices. He remained in the Schenectady offices of the Adirondack Electric Power Corporation until 1928, when he became associated with the New York Power and Light Corporation at Albany.

# Membership

## Recommended for Transfer

The board of examiners, at its meeting on April 14, 1937, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

**To Grade of Fellow**

Childerhose, E. A., senior engineer, Federal Power Commission, New York, N. Y.
Donnell, P. S., dean of division of engineering, Oklahoma Agricultural and Mechanical College, Stillwater, Okla.
Eshbach, O. W., special assistant, personnel department, American Telephone and Telegraph Company, New York, N. Y.
Newton, J. M., president, The Roland T. Oakes Company, Holyoke, Mass.
4 to Grade of Fellow

**To Grade of Member**

Baines, H. A., technical assistant to executive staff, The Narragansett Electric Company, Providence, R. I.
Barron, D. W., vice-president and assistant engineer, Albert F. Ganz, Inc., New York, N. Y.
Clary, H. L., erecting engineer, Allis-Chalmers Manufacturing Company, Boulder City, Nev.
Connell, D. J., electrical engineer, The Scranton Electric Company, Scranton, Pa.
Crumley, H. L., electrical engineer, E. M. Gilbert Engineering Corporation, Reading, Pa.
Defandorf, F. M., physicist, National Bureau of Standards, Washington, D. C.
Linney, R. W., transmission and protection engineer, Southwestern Bell Telephone Company, Oklahoma City, Okla.
Long, Marvin, engineering assistant to toll fundamental plan engineer, Bell Telephone Company of Pennsylvania, Philadelphia.
Peterson, J. B., aeronautical engineer, National Bureau of Standards, Washington, D. C.
Schuetz, R. F., audio facilities engineer, National Broadcasting Company, Inc.; New York, N. Y.
Wichum, Victor, chief engineer, C. J. Tagliabue Manufacturing Company, Brooklyn, N. Y.
Wilfley, V. B., electrical engineer, Westinghouse Electric & Manufacturing Company, Portland, Ore.
12 to Grade of Member

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. If the applicant has applied for direct admission to a grade higher than Associate, the grade folllows immediately after the name. Any member objecting to the election of any of these candidates should so inform the national secretary before May 31, 1937 or July 31, 1937, if the applicant resides outside of the United States or Canada.

Allen, S. R., Washington Water Power Company, Spokane, Wash.
Anderson, J. R., New York Worlds Fair, Inc., New York, N. Y.
Atkinson, J. M., California Institute of Technology, Los Angeles, Calif.
Banks, G. F., Commonwealth Edison Company, Chicago, Ill.
Bauerle, J. L., Cleveland Electric Illuminating Company, Cleveland, Ohio.
Baur, H. W., Eastman Kodak Co., Rochester, N. Y.
Bender, D. S., 1835 Arch Street, Philadelphia, Pa.
Bingham, H. C., Cleveland Electric Illuminating Company, Cleveland, Ohio.
Bittrick, W. E., Consolidated Gas, Electric Light, and Power Company, Baltimore, Md.
Brand, S. (Member) Bell Telephone Laboratories, Inc., New York, N. Y.
Brewster, L. C., Ohio Bell Telephone Company, Cleveland, Ohio.
Butler, C. H., Portland General Electric Company, West Linn, Ore.
Carey, A. J., New York Telephone Company, Brooklyn, N. Y.
Carr, B. P., The Commonwealth & Southern Corporation, Jackson, Mich.
Chase, C. N., New York Rapid Transit Corp., Brooklyn, N. Y.
Chase, G. E., Public Utilities Commission, Bowmanville, Ont., Canada
Colby, P. S., Kansas Gas and Electric Company, Wichita, Kans.
Crevi, I. P. (Member) Westinghouse Electric & Manufacturing Company, New York, N. Y.
Cupitt, I. M. (Member) American Telephone and Telegraph Company, New York, N. Y.
Dailey, J. A., General Electric Company, Kansas City, Mo.
Devereaux, A. J., Central Nebraska Public Power and Irrigation District Hastings, Nebr.
Dietsch, R. C., Texaco Development Corporation, Los Angeles, Calif.
Edwards, J. H. (Member) General Cable Corporation, New York, N. Y.
Enquist, E. A. Jr., Consolidated Edison Company of New York, Inc., New York, N. Y.
Fletcher, G. R. (Member), Virginia Public Service Co., Alexandria, Va.
Galle, Paul F., Tennessee Valley Authority, Knoxville, Tenn.
Garrett, P. A. (Member) Commonwealth Edison Company, Chicago, Ill.
Gaskill, H. R., 4415 Pine Street, Philadelphia, Pa.
Gatchell, O. W. (Member) Cooper Wire Engineering Association, Washington, D. C.
Gibson, G. P., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.
Hartzell, H. W., Locke Insulator Corporation, Baltimore, Md.
Henderson, O., Ohio Bell Telephone Company, Cleveland, Ohio.
Henderson, W. D., 3721 Locust Street, Philadelphia, Pa.
Hendricks, J. B., The Milwaukee Electric Railway and Light Company, Milwaukee, Wis.
Herter, C. C., New York and Queens Electric Light and Power Company, Flushing, N. Y.
Holme, S. A. (Member) General Electric Company, Schenectady, N. Y.
Hughes, P. E., Star Route, Newburgh, N. Y.
Jirka, F. J., Public Service Company of Northern Illinois, Chicago, Ill.
Jones, J. O., Pacific Gas and Electric Company, Oakland, Calif.
Jordan, T., American Smelting and Refining Company, Garfield, Utah.
Julian, L. P., Duke Power Company, Charlotte, N. C.
Kelley, R. R., Westinghouse Electric and Manufacturing Company, Sharon, Pa.
Kethley, B. L., South East Joslyn Company, Atlanta, Ga.
Kocsis, P., R. K. O., Franklin Theatre, New York, N. Y.
Koester, H. F. (Member) New York and Queens Electric Light and Power Company, Flushing, N. Y.
Kostriza, J. A., 90 St. Mark's Place, St. George, Staten Island, N. Y.
Lack, F. R. (Member) Bell Telephone Laboratories, Inc., New York, N. Y.
Latta, E., Airway Electric Appliance Corp., Toledo, Ohio.
Lukacs, J. J., Bell Telephone Laboratories, Inc., New York, N. Y.
MacDonald, L. L., Public Service Electric and Gas Company, Newark, N. J.
Mancini, P. S., 65 Chatham Street, Providence, R. I.
Markuson, O. S., Bell Telephone Laboratories, Inc., Baltimore, Md.
Marshall, A. E. (Member) Monsanto Chemical Company, St. Louis, Mo.
Marshall, M. B. Jr., Jackson and Moreland, Boston, Mass.
Matthysse, I. F., Burndy Engineering Company, New York, N. Y.
Maull, J. R., Massachusetts Institute of Technology, Cambridge, Mass.
Mayberry, W. R., H. J. Heinz Company, Pittsburgh, Pa.
McCarthy, E. J., Bell Telephone Laboratories, Inc., New York, N. Y.
McElroy, C. H., Department of Water and Power, Los Angeles, Calif.
McIntosh, F. H. (Member) Pacific Coast Radio Engineer, for Graybar Company, San Francisco, Calif.
McNeice, L. G. (Member), Orillia Water, Light, and Power Commission, Orillia, Ont., Canada.
McWilliams, H. G., Southern California Telephone Company, Los Angeles, Calif.
Mead, S. P. (Mrs.) Bell Telephone Laboratories, Inc., New York, N. Y.
Mintz, L. L., Parker-Kalon Corporation, New York, N. Y.
Morgan, G. W., E. I. Du Pont Company, Richmond, Va.
Moseley, F. N., Southwestern Bell Telephone Company, St. Louis, Mo.
Murdock, H. E., Montana Power Company, Bozeman, Mont.
Murray, T. F., United Light and Power Engineering and Construction Company, Davenport, Iowa.
Nebe, H. G., WSMB Radio Station, New Orleans, La.
Nelson, A. E., Jr., Arkansas Power and Light Company, Pine Bluff, Ark.
Nelson, R. D., Line Material Company, South Milwaukee, Wis.
Newton, E. G. (Member) General Electric Company, Pittsfield, Mass.
Nicholson, H. H., Electric Storage Battery Company, Cleveland, Ohio.
Nofrey, C. E., 3014 Clay St., San Francisco, Calif.
Norman, G. H. L., Aerovox Corporation, Brooklyn, N. Y.
Page, F. M., The Reliance Electric & Engineering Company, Cleveland, Ohio.
Paige, H. W. (Member) Peters and Peters, Inc. New York, N. Y.
Patterson, H. M., 825 Union Trust Building Washington, D. C.
Peck, R. R., Kansas City Power and Light Company, Kansas City, Mo.
Rahe, E. P., Western Electric Company, Baltimore, Md.
Rohr, E. K., Iowa State College, Ames.
Rohwer, O. J., Sargent and Lundy, Inc., Chicago, Ill.
Roush, C. G., Westinghouse Electric & Manufacturing Co., Kansas City, Mo.
Safranek, R. C., Washington Water Power Company, Spokane, Wash.
Schatz, G. W., Pennsylvania Power & Light Company, Allentown, Pa.
Scott, J. A., United States Treasury Department, Washington, D. C.
Seels, H. F., R.C.A. Manufacturing Corporation, Harrison, N. J.
Sickel, E. C., Northern States Power Company, West St. Paul, Minn.
Small, A. R. (Member) Underwriters' Laboratories Inc., Chicago, Ill.
Smith, L., Appalachian Electric Power Company, Charleston, W. Va.
Softli, R. R. B., 247 West 63d Street, New York, N. Y.
Spears, V. W., Public Service Company of Indiana, Bedford, Ind.
Stein, A. D. Jr., General Cable Corporation, New York, N. Y.
Stickel, O., A. I. Smith Corporation, Milwaukee, Wis.
Sullivan, D. E. (Member) Westinghouse Electric and Manufacturing Company, New York, N. Y.
Sullivan, J. W., S. S. White Dental Manfacturing Company, Princess Bay, S. I., N. Y.
Summers, S. D., Tri-State College, Angola, Ind.
Targonski, E., Arrow Hart and Hegeman Electric Company, Hartford, Conn.
Taylor, R. W., Tennessee Valley Authority, Knoxville, Tenn.
Thomas, P. E. (Member) Rochester Gas and Electric Corporation, Canandaigua, N. Y.
Thompson, W. B., E. M. Gilbert Engineering Corporation, Reading, Pa.
Tilson, H. MacM. (Member) San Francisco–Oakland Bay Bridge, San Francisco, Calif.
Tindall, H. D., Wagner Electric Corporation, St. Louis, Mo.
Todd, A. W., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.
Tollefson, M. W., Century Electric Company, St. Louis, Mo.
Traves, J. R., Bell Telephone Company of Canada, Toronto, Ont., Canada.
Vitale, R. L., Department of Water Supply, Gas and Electricity, Richmond, N. Y.
Wallace, T. M., General Electric Company, Erie, Pa.
Warfield, W. (Member), Tampa Electric Company, Tampa, Fla.
Westerkamp, P. R., Consolidated Edison Company of New York Inc., New York, N. Y.
White, P., Phoenix Engineering Corporation, New York, N. Y.
Widess, M. B., Western Geophysical Company, Los Angeles, Calif.
112 Domestic

**Foreign**

Accioly, P. B., Rio de Janeiro Tramway Light and Power Company, Brazil, S. A.
Barney, G. C. (Member), American Telegraph and Telephone Company and Bell Telephone Laboratories Inc., London, England.
Johnson, F. J. (Member) Honolulu Rapid Transit Company, Ltd., Honolulu, Hawaii.
Lazarus, V. E., "Sunnyside" Waltair, South India.
4 Foreign

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute record. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Evans, Maldwyn F., Canadian Comstock Company, Ltd., Star Building, Toronto, Ont., Canada.
Hale, Edward E., Public Service Commission of New York, 80 Centre St., New York, N. Y.
Little, Leroy C., 3414—17th St., N., Cherrydale, Va.
Nash, G. H., 2–A Holland Road, London W.14, England.
Schaefer, Philip E., 5154 St. Paul Avenue, Chicago, Ill.
Wickel, F. A., Pier 42, Dollar S. S. Lines, San Francisco, Calif.
6 Addresses Wanted

# Engineering Literature

## New Books in the Societies Library

Among the new books received at the Engineering Societies Library, New York, recently, are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface of the book in question.

VDE-FACHBERICHTE, volume 8, 1936. Berlin-Charlottenburg, Verband Deutscher Elektrotechniker. Illustrated, 12x8 in., paper, 10.20 rm.; bound, 13.50 rm. Contains papers delivered at the 1936 meeting of the Verband Deutscher Elektrotechniker. Discusses many branches of electrical engineering: power generation, distribution, communications, lighting, and high-frequency engineering.

SYMPOSIUM on RADIOGRAPHY and X-RAY DIFFRACTION METHODS, held at the 39th Annual Meeting of the American Society for Testing Materials, Atlantic City, N. J., June 30–July 1, 1936. Philadelphia, American Society for Testing Materials, 1937. 350 pages, illustrated, 9x6 in., cloth, $4.00. A collection of papers on the uses of X rays and gamma rays for testing materials. Provides an account of the available methods and suggests future developments.

PROTECTION of ELECTRIC PLANT. By P. F. Stritzl. London and New York, Pitman Publishing Corporation, 1936. 200 pages, illustrated, 9x6 in., cloth, $6.00. Provides a review of developments in protective devices. Chapters are devoted to the protection of generators, transformers, and high- and low-voltage lines

PERFORMANCE and DESIGN of ALTERNATING CURRENT MACHINES. By M. G. Say and E. N. Pink. London and New York, Pitman Publishing Corporation, 1936. 552 pages, illustrated, 9x6 in., cloth, $6.00. Limited to the principal types of a-c machines; the transformer, the 3-phase induction motor, and the synchronous motor and generator. Outlines the theory of each, and discusses details of performance, control, testing, construction, and design.

MANAGING for PROFIT. By C. E. Knoeppel with the collaboration of E. G. Seybold. New York and London, McGraw-Hill Book Company, 1937. 343 pages, illustrated, 9x6 in., cloth, $3.50. Discusses working methods for profit planning and control and describes recently developed aids to management in the way of profit-making tools and methods.

INDEX to ASTM STANDARDS and TENTATIVE STANDARDS, January 1, 1937. Philadelphia, American Society for Testing Materials. 118 pages, 9x6 in., paper, gratis. Enables the user to ascertain whether the society has issued standard or tentative standards, test methods, or definitions upon any engineering material or subject, and to locate the volume in which the latest information is found.

ELEMENTS of APPLIED ELECTRICITY. 4 volumes. By B. C. Chatterjee. 2 edition. Benares, India, Shiva Narayan Chatterjee, 1 Laksha Road, 1931–1936. 8x5 in., cloth. Volume 1, 412 pages; volume 2, 736 pages; volumes 3–4, 1142 pages, apply. Presents a course in practical engineering intended primarily for students.

HISTORY of the DISCOVERY of PHOTOGRAPHY. By E. Potonniée, translated by E. Epstean. New York, Tennant and Ward, 1936. 272 pages, 10x6 in., cloth, $8.00. Affords an account of the origin of photography and of its development to the end of the Daguerrean period, about 1651.

THEORETICAL ASTROPHYSICS, Atomic Theory and the Analysis of Stellar Atmospheres and Envelopes. By S. Rosseland. Oxford, England, Clarendon Press; New York, Oxford University Press, 1936. 355 pages, illustrated, 10x6 in., cloth, $8.00. Presents a mathematical and physical picture of the constitutions of stellar atmospheres, gaseous nebular and inter-stellar clouds projected to atomic physics as a background.

Introduction to PHYSICAL OPTICS. By J. K. Robertson. 2 editions. New York, D. Van Nostrand Company, 1935. 471 pages, illustrated, 9x6 in., cloth, $4.00. Aims to provide a comprehensive introduction to the subject.

MEN, MONEY, and MOLECULES. By W. Haynes. Garden City, N. Y., Doubleday, Doran and Company, 1936. 214 pages, illustrated, 8x5 in., leather, $1.50. An informal history of the American chemical industry, intended for the general reader.

Deutsches Museum Abhandlungen und Berichte, Jg. 8, Heft. 1. GRÖSZE und MASSE der MOLEKÜLE und ATOME. By E. Rüchardt. Berlin, VDI-Verlag, 1936, 27 pages, illustrated, 8x6 in., paper, 0.90 rm. A brief account of the methods used for investigating the size and mass of molecules and atoms.

74. VDI-HAUPTVERSAMMLUNG DARMSTADT 1936 und 80-Jahrfeier des Vereines Deutscher Ingenieure. FACHVORTRAGE. Berlin, VDI-Verlag, 1936. 406 pages, illustrated, 12x8 in., paper, 6 rm. Contains papers presented at the annual meeting of the Verein Deutscher Ingenieure. Special attention is given to problems connected with national resources in food, raw materials, and power.

PHOTOGRAPHY. By C. E. K. Mees. New York, Macmillan Company, 1937. 226 pages, illustrated, 9x6 in., cloth, $3.00. A review of the whole subject of photography. Based upon a series of Christmas lectures at the Royal Institution, London; simple and popular in style.

ART and the MACHINE, an Account of Industrial Design in 20th-Century America. By S. Cheney and M. C. Cheney. New York, McGraw-Hill Book Company (Whittlesey House), 1936. 307 pages, illustrated, 10x7 in., cloth, $3.75. Discusses the new field of "industrial design." Traces the development of this blending experiment through the last few decades.

DEUTSCHES MUSEUM. Abhandlungen und Berichte, Jg. 6, Heft 5, 1936. ENTWICKLUNG der KINOTECHNIK. By R. Thun. Berlin, VDI-Verlag, pages 111–138, illustrated, 8x6 in., paper, 0.90 rm. Gives a brief, popular outline of the development of moving pictures.

EVERY DAY BUT SUNDAY, the Romantic Age of New England Industry. By J. F. Copeland. Brattleboro, Vt., Stephen Daye Press, 1936. 294 pages, illustrated, 9x6 in., cloth, $2.50. The story of Mansfield, Mass., carried to the end of the nineteenth century. Gives a picture of an early industrial community; of considerable historic interest.

HANDMAIDEN of the SCIENCES. By E. T. Bell. Baltimore, Williams and Wilkins Company, 1937. 216 pages, illustrated, 9x6 in., cloth, $2.00. Shows that mathematics, in one sense queen, is also the servant of the sciences. Explains and demonstrates the usefulness of such concepts as conic sections, fourth and higher dimensions, continuity and discreteness, chance and probability.

COMMUNICATION ENGINEERING. By W. L. Everitt. 2nd edition. New York and London, McGraw-Hill Book Company, 1937. 727 pages, illustrated, 9x6 in., cloth, $5.00. Treats the subject of communication systems as distinct from power systems. Consideration is given only to general and fundamental aspects of network theory and layout. Based on the assumption that the reader already has the necessary groundwork in principles of a-c and d-c systems, and leaves specific applications to be studied in the field. The chapters on complex quantities and medium- and high-requency measurements have been deleted.

DEUTSCHES MUSEUM, Abhandlungen und Berichte, Jg. 8, Heft 6, 1936. Die ENTWICKLUNG der FUNKENTELEGRAPHIE, by J. Zenneck. Berlin, VDI-Verlag, 1936. Pages 139–171, diagrams, 8x6 in., paper, 0.90 rm. Traces the fundamental ideas of wireless telegraphy and the principal steps in its development.

ELECTRICAL MEASUREMENTS, Precise Comparisons of Standards and Absolute Determinations of the Units. By H. L. Curtis. New York and London, McGraw-Hill Book Company, 1937. 302 pages, illustrated, 9x6 in., cloth $4.00. Deals with methods used in absolute measurements of electric units. The introductory chapters cover definitions and the history of electrical units. Discusses each absolute measurement determination given, but considers only the precise ones. Brief appendixes give the computation of elliptic integrals and the results of absolute determinations of electrical units in various countries.

ELEKTRISCHE MESSGERÄTE und MESSEINRICHTUNGEN. By A. Palm. Berlin, Julius Springer, 1937. 231 pages, illustrated, 9x6 in., cloth, 16.50 rm. A textbook for engineers and students, presenting the principles and construction of electrical measuring instruments and their practical applications.

ELEMENTS of ELECTRICITY. By W. H. Timbie. 3rd edition. New York, John Wiley and Sons, 1937. 569 pages, illustrated, 9x6 in., cloth, $3.00. Provides a brief treatment of a few fundamental ideas that a technical student must know well. Presents new material on electronics and vacuum tubes, and covers electrical measurements, batteries, and d-c and a-c machinery.

(The) IDENTITY THEORY. By B. Stevens. 2nd edition, revised and enlarged. Manchester, England, Sherratt & Hughes; New York, C. E. Stechert and Co., 1936. 248 + 16 pages, illustrated, 9x6 in., cloth, 7s. 6d. Presents a mathematical theory of space-time relations as applied to the universe. Text is divided into articles, each one presenting a single argument. The reader is assumed to have had mathematical training.

INDUSTRIAL ELECTRICITY and WIRING. By J. A. Moyer and J. F. Wostrel. 2nd edition. New York and London, McGraw-Hill Book Company, 1937. 502 pages, illustrated, 8x6 in., cloth, $2.75. Based on the latest regulations of the National Electrical Code. Covers fundamental theory and practical wiring information.

INSTRUMENT TRANSFORMERS. By B. Hague. London, Sir Isaac Pitman and Sons; New York, Pitman Publishing Corporation, 1936. 656 pages, illustrated, 9x6 in., cloth, $10.00. An extensive summary of papers and magazine articles, with the object of giving a general view of the complete field covering theory, construction, characteristic features, and testing of instrument transformers.

JONES ANTENNA HANDBOOK, 1937 edition. By F. C. Jones. San Francisco, Pacific Radio Publishing Company, 64 pages, illustrated, 9x6 in., paper, $0.50. Aims to provide practical guidance in the selection and construction of the best type of antenna for any specified purpose and location.

LEHRBUCH der HOCHFREQUENZTECHNIK. By F. Vilbig. Leipzig, Akademische Verlagsgesellschaft, 1937. 775 pages, illustrated, 9x6 in., cloth, 32.80 rm. Aims to provide a review of theory and current practice in the field of high-frequency engineering.

MARINE ELECTRIC POWER. By Q. B. Newman. New York, Simmons-Boardman Publishing Corporation, 1937. 159 pages, illustrated, 9x5 in., cloth, $2.00. A collection of material reprinted from *Marine Engineering* and *Shipping Review*, designed to present simply the basic principles underlying the electrical equipment used on ships. Intended primarily for those who have had little groundwork in physics and mathematics.

MATHEMATICAL RECREATIONS and ESSAYS. By W. W. R. Ball. 10th edition. London and New York, Macmillan and Company, 1931. 366 pages, illustrated, 8x5 in., cloth, $3.50. Covers arithmetical, geometrical, and mechanical problems, magic squares, and chess and playing-card recreations. Contains discussions of cryptographs, ciphers, and various famous calculating prodigies.

NATIONAL ASSOCIATION OF RAILROAD and UTILITIES COMMISSIONERS. PROCEEDINGS of 48th Annual Convention, held at Atlantic City, N. J., November 10 to 13, 1936. New York, State Law Reporting Co., 541 pages, tables, 9x6 in., cloth, $6.00. Contains the discussions on the topics set for this meeting. Includes uniform systems of accounts for gas and electric companies, the operation of the federal motor-carrier act, the regulation of electric utilities and of telephone companies, progress in public-utility regulation, and public-utility rates.

**Engineering Societies Library**
29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a co-operative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Industrial Notes

**Large Generating Units on Order.**—Orders have been placed by the Public Service Electric & Gas Co. (of N. J.) for a 50,000-kw turbine-generator and 2 high pressure steam boilers to be installed at the Essex generating station in Newark. This will increase the station's generating capacity from 193,000 kw to 243,000 kw. Boilers will be operated at 1,400 pounds pressure and at a temperature of 950 F, the highest combined temperature and pressure ever to be utilized in a generating station in this country. The turbine-generator will be built by the General Electric Co., and the steam boilers by the Babcock & Wilcox Co. Boilers will be equipped to burn either oil or pulverized coal and each will have a capacity of 605,000 pounds of steam per hour.

A third 110,000-kw turbine-generator unit will be added to the present River Rouge power plant of the Ford Motor Co. at Detroit, making the total installed capacity 350,000 kw. The new vertical compound turbine will be a duplicate of the second 110,000-kw unit, recently installed, for steam conditions of 1,200 pounds, 900 F. Hydrogen cooling is employed for the generators, which will be the 13th and 14th large turbine-driven units designed for hydrogen cooling to be built at the Schenectady works of the General Electric Co.

**New Equipment for Pennsylvania Railroad.**—After the April 14th directors' meeting of The Pennsylvania Railroad announcement was made that 2,800 new steel freight cars and the chassis for 11 new electric passenger locomotives of the heaviest and most powerful design will be constructed at the railroad's Altoona, Pa., works. The locomotives, known as the GG-1 type, will be assembled at Altoona with electrical parts supplied by the electrical manufacturing companies. The total cost of the equipment will be slightly in excess of $10,750,000. The new locomotives will supplement 58 others of the same type and 28 of a slightly different type already in use for high-speed passenger service in the electrified territory, and will provide part of the additional motive power required for the extension of the electrification now under way westward to Harrisburg, Pa.

**Fansteel Annual Report.**—The recently issued annual report of the Fansteel Metallurgical Corp., No. Chicago, Ill., shows an increase of slightly more than 50 per cent in sales over those for the corresponding period of 1936, despite a "sit-down" strike in February which interrupted all operations for nearly 2 weeks. The products of the company are based upon 4 metals—tantalum, columbium, tungsten and molybdenum having wide application in many industries, including the electrical manufacturing field. Tantalum is used in the production of electronic tubes and is the basis of the Balkite rectifiers and condensers. In addition to its use in lamp filaments tungsten has numerous uses in vacuum tubes, X-ray tubes, and neon signs. One of its principal uses is that for electrical contacts. The most common use for molybdenum is in electronic tubes and incandescent lamps. It is also used extensively in mercury switches and electrical contacts. Development of new metal alloys to be added to the company's line of products is in process and should be completed this year.

**Manufacturers Report Record Orders.**—General Electric Co. reports sales billed for the first quarter of 1937 as $73,412,420, compared with $51,423,071 for the same quarter last year, an increase of 43 per cent. Orders received during the first quarter of this year amounted to $105,747,030, compared with $59,569,879 for the same quarter of 1936, an increase of 78 per cent. This was the largest first quarter in the history of the Company.

Orders booked for the 3 months ending March 31, amounting to $74,242,584, by Westinghouse Electric & Mfg. Co., were the highest for any quarter on record and unfilled orders for the same period were the highest since 1923. The orders booked for the first 3 months of this year show an increase of 75 per cent over the same period in 1936.

**General Electric Opens Exhibit.**—An exhibit of electrical products for industry has been opened in the General Electric Building, 570 Lexington Ave., New York City. It brings together, in 7,000 square feet of floor space, a complete line of representative products of General Electric and its affiliates. Cable, distribution equipment, fractional-horsepower and integral motors, industrial control, industrial heating, lighting, meters and instruments, police radio, switchgear, transportation products, turbines and welding; the products of the incandescent lamp department, air conditioning department, and the construction material division and the plastics division of the appliance and merchandise department; and the products of the Trumbull Electric Co., General Electric X-Ray Corp., Warren Telechron Clock Co., General Electric Vapor Lamp Co., Bailey Meter Co., Locke Insulator Corp., and Carboloy Co., are on display. Much of the equipment is in operation.

# Trade Literature

**Insulators.**—Catalog supplement and 2 articles, 5 pp. Outlines the theory of the design of O-B radio-interference-free pintype insulators, known as "Silentypes;" includes complete descriptions of the units available. Ohio Brass Co., 360 N. Main St., Mansfield, O.

**Relays.**—Folder. Describes a comprehensive line of relays, timing devices, thermostats, electric counters, melting pots, ladles, etc. Struthers Dunn, Inc., 139 North Juniper St., Philadelphia, Pa.

**Recording Instruments.**—Bulletin GEA-1061F, 32 pp. Describes strip-chart recording instruments; illustrates some of the more important improvements that have been made in the complete line of portable and switchboard type CD equipment. General Electric Co., Schenectady, N. Y.

**Circuit Breakers.**—Bulletin 33-226, 8 pp. Describes construction, operation and applications of type F-124 indoor oil circuit breakers for industrial and central station use. Rated at 50,000-kva interrupting capacity, manually and electrically operated, non-automatic and automatic, single throw. Westinghouse Electric & Mfg. Co. E. Pittsburgh, Pa.

**Motor-Control Units.**—Bulletin 67, 16 pp. Describes steel-clad motor-control units, each complete with disconnect switches, bus bars, contactor-type switching mechanisms, safety door-interlocks, meters and all the equipment necessary to meet the requirements of the individual application. The Electric Controller & Mfg. Co., Cleveland, O.

**Magnetic Relays.**—Bulletin 81, 8 pp. Lists more than 100 relays for intermediate duty (10–15 amperes) on d-c and a-c circuits for 2 and 3 wire control. Includes valuable coil and contact data, contact arrangements, enclosures, and illustrates relays assembled from standard parts for use on special applications. Ward Leonard Electric Co., Mount Vernon, N. Y.

**Aerial Cables.**—Bulletin GEA-2215, 52 pp. The book is intended mainly as a treatise on power cable and aims to facilitate selection of insulated cable for overhead transmission and distribution. Tables are presented showing the current carrying capacities of cables in air and also methods of calculating regulation. Some installation data is included in the bulletin. General Electric Co., Schenectady, N. Y.

**Trolley Coaches.**—Bulletin B2088, 32 pp., "The Modern Trolley Coach." Includes the essential data on typical electric-powered coaches of which there are at present over one thousand in use. The booklet traces the development and growth of this means of commutative transportation and studies its field of application. Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

**Utility Distribution Supplies.**—Catalog 37, 166 pp. A comprehensive listing of electrical distribution and transmission underground and street lighting equipment. Items included cover heavy and secondary cable racks, guy guards, anchors, clamps and clevises of many types, cross arms, insulator and pole top pins, brackets, glass and porcelain insulators, fuswitches, mast arms and accessories, etc. Utilities Service Co., Allentown, Pa.

**Street Lighting Equipment.**—Catalog Secs. 60–250,–260,–270,–275,–280,–300,–330,–340 and –450. Describe lighting standards and fittings. These sections include descriptions of cast iron standards, Hollowspun Granite (concrete) standards, Union Metal steel standards, top sections and casings for standards, brackets and equipment for poles, ornamental crooks; also luminaires for street lighting, street lighting glassware, and paragon and octagonal pendants. Westinghouse Electric & Mfg. Co., Lighting Division, Cleveland, O.

# High Lights

**Radiobroadcasting.** Although radiobroadcasting stations in the United States operate on frequencies assigned so as to provide service to listeners throughout the country, practical limitations make impossible good reception on every one of the 100 frequency channels in the band of medium wave lengths for any one listener (*pages 666–70*). Frequencies of 30 or more megacycles per second have certain characteristics that make them particularly suitable for local broadcasting, and essential for television with present standards, but working frequencies in this region by no means are unlimited. Because such waves are limited in range almost to optical paths, they are unlikely to replace the medium-frequency waves now used for broadcasting over large areas (*pages 662–6*).

**Vibration.** Increasing the speed of machines imposes upon the engineer the necessity for seeking some means of reducing the amount of noise and vibration transmitted to the structures in which the machines are housed. Vibration isolation is one way of accomplishing this (*pages 735–8*). Instruments for precision measurement of vibration must measure amplitude, velocity, and acceleration. Fundamental requirements in the design of a general-purpose measuring instrument determining the useful frequency range, accuracy, amplitude range, and effect of the instrument on the vibrating body (*pages 706–10*).

**Insulation Co-ordination.** For several years a joint committee of Edison Electric Institute and National Electrical Manufacturers Association has been considering the subject of insulation co-ordination. As a result, basic impulse insulation levels now have been agreed upon, which constitutes the first step in the program (*pages 712–14*). A subcommittee has studied the factors that caused divergence in flashover values obtained by different commercial laboratories for the same test piece on impulse testing, and impulse and 60-cycle flashover values for rod gaps and insulators now have been agreed upon (*pages 711–12*).

**Recovery Voltages.** Determination of circuit recovery voltages for many different system conditions by actual tests is expensive and limited in scope. The voltages may be determined by analytical methods, which cannot consider all factors without becoming extremely complex, or by reproducing the system in miniature on an a-c calculating board and actually measuring the desired quantities (*pages 695–705*).

**Distribution Protection.** Investigation of the requirements of distribution systems for protection against surges shows that protectors should have a discharge capacity of 100,000 amperes, although a lower value may be satisfactory, and that a high degree of protection may be obtained in voltage classes up to 13.8 kv with a ratio of 9 to 1 for the protective-device discharge voltage and normal-frequency voltage (*pages 683–8*).

**Transformer Insulation.** For many years the transformer subcommittee of the AIEE committee on electrical machinery has been developing standards for the insulation strength of transformers. Impulse testing of insulation is one of the recent developments, and now the expression of impulse strength in terms of kilovolts instead of gap spacing is authorized (*pages 749–54*).

**Insulation Levels.** Insulation levels of transformers and other power system equipment should be selected according to the performance of the protective equipment such as lightning arresters and gaps; the level selected must be above the maximum surge voltage presumed to be allowed by the protective device on a volt-time basis over the range of time selected (*pages 677–82*).

**Security of Engineering Employment.** Data supplied by some 35,000 engineers shows that the degree of economic security among professional engineers, as evidenced by possession of an employment contract covering some period of time, or by pension privileges, is negligible (*pages 655–61*).

**Insulation Co-ordination.** Economy and the protection of service and equipment are the objectives of insulation co-ordination. Many data on the insulation strength of major equipment and protection available have been collected and are presented in graphical form in this issue (*pages 715–20*).

**Spill Gaps.** Theory and performance of spill gaps for the protection of electric circuits and equipment from lightning, together with a discussion of the selection of insulation levels co-ordinated with this type of protection, are presented in this issue (*pages 689–94*).

**Section and Branch Report.** The annual report of the Section and Branch activities for 1936–37 show that 621 meetings were held by AIEE Sections during the year, 81 more than during the preceding year; Student Branches held 1,363 meetings, by far the most ever held in a fiscal year (*pages 762–5*).

**District Meeting at Buffalo.** Active discussions on electrical equipment for steel mills and power system operation featured the Institute's North Eastern District meeting held recently at Buffalo, N. Y. The meeting included also a Student Branch convention (*pages 758–61*).

**Rotor Balancing.** Small gyro rotors such as are used in airplane flight instruments require balancing in production at speeds of 30,000 or 40,000 rpm. A machine using electrical means to detect unbalance is replacing older methods (*pages 729–34*).

**Oil-Filled Cables.** Improvements in oil-filled cable and associated equipment, have made possible economy and comparatively simple layout for about 100 miles of 66-kv oil-filled single-conductor cable now being installed in Chicago, Ill. (*pages 739–48*).

**Development of Standards.** The AIEE, with its technical committees covering all phases of the electrical art, many of which have active subcommittees, has an ideal setup for the development of material for electrical standards (*pages 653–4*).

**Prize Awards.** National prizes for technical papers presented at Institute meetings during 1936 have been awarded. Prize awards also have been announced by some of the Districts (*page 756*).

**Cathode-Ray Oscillograph.** A historical review of advances in the design of high-speed cathode-ray oscillographs, and a description of a new type of oscillograph, are included in this issue (*pages 721–8*).

**AEC Patent Report.** Action taken by the committee on patents of American Engineering Council during the year 1936 is summarized in the committee's annual report (*pages 766–7*).

**Noninflammable Insulating Oils.** A new type of synthetic insulating oil that obviates several of the problems heretofore associated with the use of mineral oil for insulation has been produced (*pages 671–6*).

**Summer Convention.** Final plans for the Institute's 1937 summer convention to be held at Milwaukee, Wis., June 21–25, are practically complete (*page 755*).

**New Members-for-Life.** Since June 1936, 92 members of the AIEE have become members-for-life (*page 757*).

Statements and opinions given in articles and papers appearing in ELECTRICAL ENGINEERING are the expressions of contributors, for which the Institute assumes no responsibility. Correspondence is invited on all controversial matters. ¶ Subscriptions—$12 per year to United States, Mexico, Cuba, Porto Rico, Hawaii, Philippine Islands, Central and South America, Haiti, Spain, Spanish Colonies; $13 to Canada; $14 elsewhere. Single copy $1.50. ¶ Address changes must be received by the fifteenth of the month to be effective with the succeeding issue. # What Institute Sections Are Doing

## —A Message From the President

FROM my limited viewpoints, a primary activity of other Sections is enthusiastically to receive and delightfully entertain the president. At those meetings where the president was an invited guest, but not the primary speaker, there was the greatest opportunity to learn what the Section was doing "to advance the theory and practice of electrical engineering, and the allied arts and sciences, and to maintain a high professional standing among the members." A meeting each year with a national officer or officers is most desirable, not only that the Section may learn of national activities, but even more that the national officers may be informed as to the Section's viewpoints. Several times this year, the president joined in a luncheon meeting with a Section's executive committee. These meetings were very profitable.

Undoubtedly, the most important factors in a Section's success are the enthusiasm and devotion of the Section's officers. Service to the profession appears to hold the strongest appeal for a representative electrical engineer, and the energy and time devoted to Section affairs by the Section officers is astonishing. Those Sections where this spirit is diffused most widely among the membership are certainly the most successful. Many Sections hold an executive committee meeting prior to each Section meeting, and with excellent results.

I have stressed the opportunity open to the Section to participate in national Institute affairs by nominating one or more members for appointment to the national committees, and by submitting at least one technical paper for publication in ELECTRICAL ENGINEERING. Several Sections have embraced this opportunity. In several cities I have been impressed when I learned that the program for the succeeding year was completely planned prior to the first of July. This practice permits the completion of arrangements for the speakers during the summer months, and further permits the program to be printed and distributed at the first fall meeting of the Section. When the program is so arranged, it is well balanced, best meeting the needs of the various members. If Section finances permit, the membership roster may be combined effectively with program announcements. Those Sections which are following this practice testify to its success.

Usually 9 meetings are held, and integrating the information I have secured throughout my trips, the following seems to be a good classification as to the types of meetings held: 3 meetings are addressed by out-of-Section speakers on recent developments in the field of electrical engineering; 2 inspection trips to local plants, with a short paper by an engineer connected with the plant, outlining what may be observed on the trip; 1 meeting with a paper by a member of the Section on some developments in electrical engineering; 1 meeting attended by a national officer or officers; 1 meeting with a local Student Branch (if there is a Branch in the city or the vicinity); 1 social meeting.

This division of the program has not provided any meeting relating to the broad interest of the engineer beyond his primary professional activity. Such a meeting might replace one of the meetings addressed by a local speaker, and be arranged as a joint meeting with other groups of engineers in the same city or locality. All Sections testify to the difficulty of getting enough speakers from outside the Section to cover all the desired meetings, and those which have developed the practice of securing local speakers testify to the success of this plan. Often the members are much more interested in papers relating to technical activity in their own locality than in those having no bearing on their particular professional interests.

Several Sections sponsor addresses on semi-scientific subjects having a popular appeal, not necessarily related to electrical engineering. At such a meeting it is essential to have an outstandingly interesting speaker; in some places where this plan is followed, the meetings are self-supporting. It seems to me that such a plan is quite con-

sistent with the fundamental purpose of the Institute.

Among the most interesting meetings I have attended, have been those where a Section joined with a local Student Branch. In some cases the technical papers have been presented by members of the Branch. These meetings were well attended by the older Institute members who were glad to have an opportunity to co-operate with the young engineers in training, and to encourage their professional development. In one instance, several neighboring Branches joined in an inspection trip in the morning, were entertained at lunch, held an all-afternoon technical meeting, with 6 Branch papers, and joined with the Section in a dinner followed by an address. In a Western city, an interesting custom has been developed. Each of several devoted Institute members pledged themselves to entertain a Branch member at one of the Section meetings during the year. This resulted in 2 or 3 Branch members being present at each Section meeting as individual guests of some of the older engineers. I talked to some of the student guests, and they were very strong in their expressions of appreciation. I recall another outstanding type of Section meeting where the members of the Section are quite widely distributed, and have only 4 meetings a year; but each meeting starts at 2:30 and continues all afternoon and evening. Papers are presented by both Enrolled Students and members, the total number of papers being 6 or 8. Some members drive between 150 and 200 miles to attend, but those from the more distant points are unable to stay for the evening sessions.

From my observations, the best meeting is likely to be that in which there is the most discussion. Anything that can be done to stimulate discussion is desirable. In one city, the author requested 3 or 4 acquaintances to discuss his paper. Usually it is necessary for only 3 or 4 men to start the discussion and a very wide discussion results. Where 2 or more Sections are fairly close together, joint meetings are inspiring. Such a joint meeting might be preceded by a golf match in the afternoon, both Sections joining in dinner, followed by a technical session. Such a plan permits of a larger audience for some outstanding speaker from outside the Sections participating.

If 2 neighboring Sections each plan their programs considerably in advance, it is possible to arrange for one speaker to address the 2 Sections on succeeding evenings. Such an idea has been under discussion for years, but actually is being applied successfully to only a limited extent. One somewhat remote Section has considerable difficulty in securing outside speakers and has adopted the practice of asking their own members to review the English technical publications and present a digest on one or 2 of the most important contributions.

From all quarters of the country, I have learned that inspection trips are very popular and are largely attended. More meetings of this character are undoubtedly desirable.

I feel that there should be many more members of the Institute among those electrical engineers connected with companies using electric power and electrical equipment, but manufacturing other products. The engineers of such companies desire meetings and papers recording experience with the application of electricity and electrical equipment. It is my belief that if the technical committees would develop more papers of interest to this group of engineers, the organization would be rendering a service that would be greatly appreciated and would stimulate interest. A few of the Sections are holding meetings with this group of engineers particularly in mind. "Application" papers are usually of a broad general interest.

Several of the Sections have a monthly or quarterly publication, recording the activities and plans of the Section. The expense is not very great, and the results are good.

In one or 2 Sections, I find a committee covering the broad activities of the engineer. Each Section may be interested in organizing such a committee. I have observed that the most successful Sections are usually the most social Sections. I am not quite certain as to cause and effect, whether they are most social because they are most successful, or whether they are most successful because they are the most social. Some very light and inexpensive refreshments after meetings do add to sociability. In the West where many attend from a distance, a dinner preceding the meeting is usually held. If it is possible to develop the idea that attendance at the dinner is not necessary, but open to all, good results will follow.

Many Sections have organized specialized technical groups, holding additional meetings. Interest has been good and the meetings well attended. I have heard the statement made that it is not possible to organize such a group in a particular Section because there is not any very specialized industry. To such a Section I would suggest studying the list of technical committees to see if there is not some activity of unusual interest in that locality. For example, it might be desirable in some Sections to organize a general power application technical group, in others a technical education group.

I found one Section giving a great deal of consideration to sponsoring meetings for the benefit of men interested in electrical work, but not necessarily eligible for membership in the AIEE. It certainly seems quite in accord with the fundamental purposes of our organization, that the Institute Section should take the lead in arranging for speakers, and furnishing a meeting place where all the men interested in electrical work could receive information of value to them.

In a Western city, I heard a discussion as to whether it might not be possible to broadcast a Section meeting over short-wave radio. Several members of the Section had operator's licenses. This plan might not be consistent with governmental regulations, but deserves investigation.

One chairman told me that 3 or 4 years ago they wondered what they might do to carry on effectively the work of the AIEE. They decided that no more important meeting could be held than one that would offer the opportunity to every Section member to suggest what he thought might be done. This meeting was held, and since that time the principal problem has been to cover effectively all the suggestions that were made.

Several times I heard the thought expressed that each Section should have a committee on engineering co-operation with other engineering groups in the same city or locality. It seems very desirable that the engineering

activities covering all branches of the profession should be co-ordinated. It certainly is true that many of the questions which should interest the engineer are equally interesting to all types of engineers, whether they be mechanical, civil, electrical, or otherwise. No Institute member should forget the reference in Article 1 of our Constitution to "the allied arts and sciences."

It is my hope that Chairman W. H. Timbie and all members of the Sections committee will sponsor a paper to be printed in ELECTRICAL ENGINEERING next year on the subject "What The Other Sections Are Doing."

# Development of Standards Material

## A discussion of the responsibility of AIEE committees in aiding the development of electrical standards

By V. M. MONTSINGER
FELLOW AIEE

H. E. FARRER
ASSOCIATE AIEE

FOR an industry that manufactures and uses as large a variety of apparatus as the electrical industry, the problem of the development of standards is a tremendously important one. The purposes of standards are 2-fold: In the first place, they aid in the manufacture of products that are more uniform; in the second place, they form a basis that enables purchasers to obtain bids for new apparatus on a comparable basis.

For many years one of the chief duties of the AIEE has been the formulation and maintenance of standards for all kinds of electrical apparatus and machinery. In the past, purchasers of electrical apparatus have based their purchasing specifications largely on AIEE Standards.

So long as the Institute was the principal body in formulating electrical standards, the duties of its members and committees engaged in standardization were clearly understood. When, because of rapid developments in the art, other organizations—the National Electrical Manufacturers' Association, the Edison Electric Institute, the National Bureau of Standards, the American Society for Testing Materials, and others—found it necessary to formulate standards of their own, usually consisting largely of material not considered within the scope of AIEE Standards, it became desirable to co-ordinate the work of standardization under one central agency so constituted as to assure general acceptance. In 1918, therefore, on the basis of a plan formulated by the AIEE co-operating with the other national engineering societies, the Bureau of Standards, and others, the American Standards Association, or as it then was called, the American Engineering Standards Committee, was established. This organization grew rapidly, and under its procedure were developed many standardization projects outside the electrical field. Further to expedite and correlate electrical standardization under ASA procedure, the Electrical Standards Committee was created. The principal electrical standardization groups have representatives on this electrical standards committee, thus giving assurance that when a standard has the approval of the electrical standards committee it practically has the approval of the entire electrical industry and readily is accorded the status of American Standard by final action of ASA.

With this new setup, the question naturally arises as to what are the duties and responsibilities of the AIEE committees in the formulation and maintenance of electrical standards. The opinion seems to have developed that the ASA has taken over the standards-making obligation and that the Institute no longer has an active duty in the development of standards. This is an erroneous impression which should not exist, and this article aims to show why it still is the Institute's privilege and duty to develop standards material for submission to the ASA through the electrical standards committee. The ASA Council then will decide whether the material is ready for adoption as an American Standard, or whether it is desirable to organize a sectional committee to which it may be referred, with other pertinent material, for review and revision in order to assure general acceptance.

The Institute still has an ideal setup for the development of standards material, namely, the technical committees, covering all phases of the electrical art, many with active subcommittees. The Institute also has means for immediate and wide circulation of information and

Written especially for ELECTRICAL ENGINEERING.

V. M. MONTSINGER is chairman of the AIEE standards committee and has been a member of that committee since 1928; he has also been a member of the AIEE committee on electrical machinery since 1926 (chairman 1934–36). He was chairman of the Institute's Pittsfield Section, 1923–33, and has served on advisory committees of the International Electrotechnical Commission. He is the author of many papers on the subject of transformers. Mr. Montsinger is research engineer of the General Electric Company, Pittsfield, Mass.

H. E. FARRER is assistant to the national secretary of the AIEE; he has served as secretary of the AIEE standards committee since 1923, and has been intimately associated with the work of the standards committee since that time.

data on proposed new developments. This is essential and valuable in keeping the Standards up-to-date and in avoiding long delays in final approval of revisions and of new developments.

To illustrate, the development of a typical new Standard is outlined: Some 6 or 7 years ago the electrical industry decided that consideration should be given to the development of a standard covering impulse testing of transformers. This work was assigned to the AIEE standards committee and by them to the AIEE electrical machinery committee. The machinery committee requested its transformer subcommittee, which was composed of representatives of both operators and manufacturers, to develop the new standards.

Before the standard on impulse tests could be proposed, much research work had to be done in both the laboratory and in the field. As this work went on, the results were published from time to time in ELECTRICAL ENGINEERING. This proved very helpful to the subcommittee. So much ground work had to be done that the subcommittee worked on the problem for 3 or 4 years before standards material could even be proposed, but as soon as the Proposed Standards on impulse testing were published in 1933 the industry accepted them. However, due to the rapid advances in the art and to the accumulation of new data, thought on the subject was not sufficiently crystallized until just recently to justify publication as Tentative American Standards. Publication in this form within the next few months is planned.

Had this work not been assigned to the AIEE, impulse testing of commercial transformers would have been seriously delayed—until the Standards were officially approved. In other words, due to the setup in the AIEE committees, together with the means for obtaining wide publicity for the work of the transformer subcommittee, the industry has been able to make use of the proposed standards material on impulse testing while it was in the developmental stage.

In addition to the formulation of new standards material on impulse testing, the AIEE transformer subcommittee during this time recommended several fundamental changes in the standards, all of which were accepted by the industry as soon as published.

Several years ago, it was decided to seek approval as American Standards for the AIEE Transformer Standards and at the same time to pass along the work done by the transformer subcommittee on proposed changes in those standards. After obtaining approval by the electrical machinery committee and the standards committee, the transformer standards and proposed revisions were turned over to the ASA for consideration as American Standards. To obtain such approval the ASA organized the sectional committee on transformers, *C*-57. While a great deal of work has been done by the sectional committee in getting together the material covered not only in the AIEE standards, but in the standards of other societies to be combined with them, no changes of a fundamental nature have been made by the sectional committee without having them first considered and approved by the AIEE. This is quite logical because, as pointed out hereinbefore, the ASA has no means of getting proposed fundamental changes before the industry until the standards are given final approval. This question of informing the industry of proposed changes in the standards is well illustrated in this case by the publication in ELECTRICAL ENGINEERING since 1933 of 2 reports by the AIEE transformer subcommittee. In many instances, however, it has proved more advantageous to follow a somewhat different procedure; that is, to have the reports published by the standards committee in pamphlet form for general distribution, with an announcement of their availability published in ELECTRICAL ENGINEERING.

The procedure followed by the AIEE and ASA in transformer standardization work is not limited at all to transformer problems, but can and should be followed by other committees working on standards for other types of apparatus. In other words, it is the very definite responsibility and duty of the AIEE technical committees to prepare and formulate standards material, developing it to a point where it is satisfactory to the industry. The current procedure then is for an AIEE technical committee to pass this work on to the AIEE standards committee. The standards committee then approves the material, if satisfactory, either for publication in report form, or for transmittal to the ASA for consideration and approval as American Standards.

There may be exceptions to this procedure, in which event action should be based on the conditions applying to the particular situation.

# Security of Engineering Employment

**Data obtained from 35,559 engineers by the United States Bureau of Labor Statistics in its survey of the engineering profession indicate that the degree of economic security among professional engineers, as evidenced by possession of an employment contract covering some period of time, or by pension privileges, was negligible. This is the fourth* in a series of articles reporting the results of the Bureau's survey.**

PRIOR to the onset of the depression in 1929, only nonprofessional workers were primarily concerned with the stability and security of employment. The effects of the depression years, however, were such as to bring about a quickening of interest in the subject of economic security even among professional workers. Because of this, a series of questions relating to this subject was incorporated into the Bureau's study of the engineering profession. Data were requested concerning the employment and separation contract, pension privileges, and the medium used to obtain a position, also whether or not the engineer reporting was under civil service, and what his status was with regard to patent rights.

The present article is based upon data supplied by 35,559 engineers who reported the field of engineering engaged in and who had an engineering job in December 1934.[1] Their reports indicate that 68.4 per cent of all professional engineers used personal contacts and recommendations to obtain their jobs. Those who used this medium, together with those who obtained their positions through the civil service, formed nearly $^4/_5$ of all reporting.

The degree of economic security among professional engineers, as evidenced by possession of an employment contract covering some period of time, or by pension privileges, was negligible.

In general, there appears to be little restriction upon professional engineers with regard to patent rights to inventions made by them. The extent of restriction, however, depended largely upon the engineer's field of employment and the type of work in which engaged.

## Means Used to Obtain Employment

The data furnished by engineers concerning the medium through which they obtained employment are presented in table I. These figures demonstrate that for the engineering profession as a whole, placement was not the function of any particular organization. The vast majority of professional engineers obtained their jobs through personal contacts and recommendations. This was the means used to find the position held in 1934 by no less than 68.4 per cent of the 35,559 engineers who also reported the field of engineering activity in which they were engaged. This medium of employment was reported by $^3/_4$ of the chemical, electrical, and mining and metallurgical engineers, and by slightly more than 70.0 per cent of the mechanical and industrial engineers, but by only 61.7 per cent of the civil engineers. The civil engineers, however, found more positions through civil service agencies; in fact, 2,941, or 80.0 per cent, of the 3,706 engineers who were classified under this medium were civil engineers. This is further emphasized by a consideration of the data for the 5 professional classes. Of the engineers who had engineering jobs in December 1934, 19.8 per cent of the civil engineers stated that these were found through the civil service, whereas among the remaining 4 professional classes, the range was from only 2.5 per cent for the chemical and ceramic to 4.6 per cent for the mining and metallurgical engineers.

It may be noted, however, that personal contacts and recommendations, together with civil service, accounted for 74.2 per cent of the mechanical and industrial engineers. For each of the remaining professional classes, these 2 mediums covered approximately $^4/_5$ of their respective totals, ranging from 78.4 per cent of the chemical and ceramic to 81.5 per cent of the civil engineers. Mechanical and industrial engineers reported relatively higher percentages of jobs obtained through an engineering society, a private employment agency, and newspapers. The most significant differences, however, will be noted for "medium not reported" and "any other medium." Thus, only in the case of civil, and mining and metallurgical engineers did "any other medium" embrace smaller proportions than those classified under "medium not reported." For the other 3 professional classes, this condition was reversed. Any other medium may well include a substantial number placed through their colleges, a point not covered in the questionnaire and one likely to affect the percentage noted in this classification.

Although the percentage distributions for the remaining avenues to employment do not embrace large numbers of each professional class, relatively they do present some striking contrasts. Only 2.4 per cent of all engineers reported that they obtained their positions through an engineering society. Some 3.7 and 2.7 per cent, respec-

---

* An article prepared by Andrew Fraser, Jr., of the Division of Hours, Wages, and Working Conditions, Bureau of Labor Statistics, United States Department of Labor, which article was published in the May 1937 issue of *Monthly Labor Review*. Articles reporting other phases of this survey were published in ELECTRICAL ENGINEERING as follows: "Professional Aspects of Engineering Education," August 1936, pages 863–7; "Unemployment in the Engineering Profession," February 1937, pages 216–23; "Employment in the Engineering Profession," May 1937, pages 524–31. A detailed report of the survey will be published later in bulletin form by the Bureau of Labor Statistics.

1. The numbers reported in this article as engaged in engineering work in December 1934 cannot be compared with those shown in the discussion of employment. The former were derived from all of the 35,890 engineers who reported the field of engineering in which they were engaged. The discussion of employment dealt with all those older engineers who reported in the 3 years 1929, 1932, and 1934, and all 1930–32 engineers who reported in the years 1932 and 1934. The grand total, including the 1933–34 engineers, was 35,675.

Of the 35,890 engineers who gave income data in their special field, 331 did not report the year of their birth. Hence, 35,559 constitutes the base for all subsequent relationships with field of engineering engaged in. But 1,458 of these engineers did not report as to type of work engaged in, and hence 34,101 was used as a base figure for all subsequent relationships with functional classification.

tively, of the mechanical and industrial, and mining and metallurgical engineers were so classified. For the 3 remaining professional classes, the percentages ranged from 1.4 to 1.9. Despite the fact that so few engineers reported an engineering society as their employment medium, it must be recognized that such societies are an important factor in obtaining employment for professional engineers. It is obvious that through their members there must inevitably be a pooling of information on employment prospects, both locally and nationally. Furthermore, the officials of the various societies are kept in close touch with local and national employment

**Table I. Distribution of All Engineers Reporting Medium of Obtaining Employment, by Professional Class, at End of 1934**

| Medium Used to Obtain Employment | Engineers Utilizing Each Specified Medium | | | | | |
|---|---|---|---|---|---|---|
| | All Professional Classes | Chemical and Ceramic Engineers | Civil, Agricultural, and Architectural Engineers | Electrical Engineers | Mechanical and Industrial Engineers | Mining and Metallurgical Engineers |
| | Number | | | | | |
| All mediums | 35,559 | 2,538 | 14,861 | 6,816 | 9,833 | 1,511 |
| Personal contacts and recommendations | 24,312 | 1,927 | 9,179 | 5,106 | 6,960 | 1,140 |
| Civil service | 3,706 | 63 | 2,941 | 289 | 343 | 70 |
| Engineering society | 841 | 36 | 274 | 130 | 360 | 41 |
| Private employment agency | 576 | 49 | 113 | 112 | 285 | 17 |
| Newspapers | 567 | 27 | 152 | 120 | 255 | 13 |
| Technical journals | 363 | 54 | 142 | 64 | 85 | 18 |
| United States Employment or Reemployment Service | 264 | 7 | 190 | 14 | 46 | 7 |
| Other public employment service | 268 | 15 | 169 | 26 | 54 | 4 |
| Any other medium | 2,551 | 259 | 706 | 655 | 849 | 82 |
| Medium not reported | 2,111 | 101 | 995 | 300 | 596 | 119 |
| | Per Cent | | | | | |
| All mediums | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Personal contacts and recommendations | 68.4 | 75.9 | 61.7 | 75.0 | 70.7 | 75.4 |
| Civil service | 10.4 | 2.5 | 19.8 | 4.2 | 3.5 | 4.6 |
| Engineering society | 2.4 | 1.4 | 1.8 | 1.9 | 3.7 | 2.7 |
| Private employment agency | 1.6 | 1.9 | 0.8 | 1.6 | 2.9 | 1.1 |
| Newspapers | 1.6 | 1.1 | 1.0 | 1.8 | 2.6 | 0.9 |
| Technical journals | 1.0 | 2.1 | 1.0 | 0.9 | 0.9 | 1.2 |
| United States Employment or Reemployment Service | 0.7 | 0.3 | 1.3 | 0.2 | 0.5 | 0.5 |
| Other public employment service | 0.8 | 0.6 | 1.1 | 0.4 | 0.5 | 0.3 |
| Any other medium | 7.2 | 10.2 | 4.8 | 9.6 | 8.6 | 5.4 |
| Medium not reported | 5.9 | 4.0 | 6.7 | 4.4 | 6.1 | 7.9 |

conditions as a result of their meetings and conventions; but such appointments as are made would depend rather upon personal contacts and recommendations than upon contacts made through the society's employment service. The fact, therefore, that only 2.4 per cent of all engineers reported the engineering society as their medium of employment must be interpreted in the light of these conditions.

The securing of employment through newspapers and technical journals was reported by 1.6 and 1.0 per cent, respectively, of all engineers making returns. It will be noted however that, relatively, electrical and mechanical and industrial engineers found more jobs through newspapers than did any of the other professional classes; this medium was reported by 1.8 per cent of the electrical and 2.6 per cent of the mechanical and industrial engineers, whereas, among the other classes the highest percentage was 1.1. On the other hand, technical journals as a medium of employment were of more assistance to chemical and ceramic engineers (2.1 per cent); among the remaining professional classes percentages ranged from 0.9 to 1.2.

Private employment agencies were used by only 1.6 per cent of all engineers reported. When considered together, the 2 public employment agencies embraced approximately the same proportion, namely, 1.5 per cent. A similar comparison among the 5 professional classes showed that, relatively, public agencies were of more importance to civil engineers, of whom 2.4 per cent so reported, whereas the next highest percentage was 1.0 per cent for mechanical and industrial engineers. Only 0.8 per cent of the civil engineers used private employment agencies to obtain jobs, but 2.9 per cent of the mechanical and industrial engineers did so; for the remaining professional classes, the percentages ranged from 1.1 to 1.9 per cent.

## Economic Security in the Engineering Profession

A written contract of employment and pension privileges are 2 important criteria of economic security. The efficacy of any such schemes, however, depends to a marked extent upon the nature of the employment. This is demonstrated by a comparison of the data concerning economic security among professional engineers who reported being engaged in public engineering, personal service, and private engineering.

### Civil-Service Status

The importance of civil-service status as a factor in stability of employment is shown in table II. Despite the fact that, in all, 11,177 of the engineers reporting were in the employ of public authorities in December 1934, only 45.0 per cent reported being under civil service. The proportion of all engineers with civil-service status was 48.4 per cent for positions under the Federal Government, and for employment with state and county, and municipal and other public authorities, 36.1 and 45.6 per cent, respectively. This percentage under civil service of these engineers employed by the Federal Government was higher than in the 2 other public employments, despite the enormous increase in Federal Government employment by December 1934, because of the amount of temporary employment under the work-relief programs; it may be assumed that relatively few engineers so employed would be classified under civil service. Consequently, under normal circumstances, the proportion of all engineers under civil service with the Federal Govern-

ment would be higher than 48.4 per cent. With regard to the other 2 classes of public engineering, it may be recalled that the numbers of engineers so engaged remained comparatively stable over the period 1930–34. Hence, the proportions reported being under civil service are representative of the situation.

The relative proportions of each professional class under civil service differed very markedly among the 3 classes of public engineering employment. The smallest range occurred in Federal positions—from 45.1 per cent for electrical engineers to 62.0 per cent for mining and metallurgical engineers. These 2 professional classes also constituted the extremes of the range of the proportions embraced by municipal governments, but in reverse order. Thus, of the mining and metallurgical engineers in municipal employment, 30.4 per cent, and of the electrical engineers, 57.1 per cent, had civil-service status. Relatively, the smallest numbers of each professional class under civil service were found in state and county governments. This is best exemplified by the comparative data for civil engineers; of their number 47.9 and 43.8 per cent, respectively, in Federal and municipal employments but only 38.0 per cent in state and county positions had civil-service status. But since the civil engineers comprised approximately 80.0 per cent of the 5,038 engineers under civil service, obviously such a status is a significant contributory factor to the stability of employment.

**Table II. Distribution of All Engineers Reporting as to Civil-Service Status, by Field of Activity and Professional Class, at End of 1934**

| Field of Employment and Professional Class | Number | | | | Per Cent | | | |
|---|---|---|---|---|---|---|---|---|
| | Total | Without Status | With Status | Not Reporting | Total | Without Status | With Status | Not Reporting |
| Federal Government | 4,649 | 2,084 | 2,250 | 315 | 100.0 | 44.8 | 48.4 | 6.8 |
| Chemical and ceramic | 74 | 22 | 44 | 8 | 100.0 | 29.7 | 59.5 | 10.8 |
| Civil, agricultural, and architectural | 3,620 | 1,649 | 1,734 | 237 | 100.0 | 45.6 | 47.9 | 6.5 |
| Electrical | 306 | 143 | 138 | 25 | 100.0 | 46.7 | 45.1 | 8.2 |
| Mechanical and industrial | 549 | 240 | 272 | 37 | 100.0 | 43.7 | 49.6 | 6.7 |
| Mining and metallurgical | 100 | 30 | 62 | 8 | 100.0 | 30.0 | 62.0 | 8.0 |
| State and county governments | 4,438 | 2,487 | 1,604 | 347 | 100.0 | 56.1 | 36.1 | 7.8 |
| Chemical and ceramic | 37 | 30 | 3 | 4 | 100.0 | 81.1 | 8.1 | 10.8 |
| Civil, agricultural, and architectural | 4,044 | 2,203 | 1,535 | 306 | 100.0 | 54.4 | 38.0 | 7.6 |
| Electrical | 134 | 91 | 33 | 10 | 100.0 | 67.9 | 24.6 | 7.5 |
| Mechanical and industrial | 170 | 123 | 28 | 19 | 100.0 | 72.3 | 16.5 | 11.2 |
| Mining and metallurgical | 53 | 40 | 5 | 8 | 100.0 | 75.5 | 9.4 | 15.1 |
| Municipal governments | 2,090 | 1,028 | 952 | 110 | 100.0 | 49.1 | 45.6 | 5.3 |
| Chemical and ceramic | 54 | 28 | 23 | 3 | 100.0 | 51.8 | 42.6 | 5.6 |
| Civil, agricultural, and architectural | 1,617 | 829 | 709 | 79 | 100.0 | 51.3 | 43.8 | 4.9 |
| Electrical | 238 | 88 | 136 | 14 | 100.0 | 37.0 | 57.1 | 5.9 |
| Mechanical and industrial | 158 | 70 | 77 | 11 | 100.0 | 44.3 | 48.7 | 7.0 |
| Mining and metallurgical | 23 | 13 | 7 | 3 | 100.0 | 56.6 | 30.4 | 13.0 |

## The Employment Contract

For the engineering profession as a whole, the data in table III clearly evidence a lack of economic security in terms of a written contract which would secure employment over a substantial period of time. In all, only 3,169, or 8.9 per cent, of the 35,559 engineers who reported employment in an engineering field[2] were covered by a written contract. Of these, some 0.8 per cent had a contract for less than 1 year, 3.5 per cent a contract for between 1 and 2 years, and only 0.9 per cent for 2 years or more. Engineers who did not report as to period of contract formed 3.7 per cent of the whole. No less than 91.1 per cent either answered "no" or did not furnish specific information.

Comparison of the positive returns on employment contract from all engineers in the 3 broad fields of engineering activity shows that use of the contract was most common in personal service—primarily education.

For engineers under contract in the personal-service field the most common contract period (reported by 25.6 per cent of the 2,778 engineers so engaged) was from 1 to 2 years. Some 4.0 per cent were under contract for periods of 2 years or longer. Although the corresponding percentages for public engineering were much lower than for personal service, they were higher than for private engineering. For employment contracts under 1 year, however, private exceeded public engineering (1.0 per cent, as against 0.5 per cent). Of all reporting engineers engaged in public engineering, 2.0 per cent had contracts for 1 and under 2 years, and 1.1 per cent for periods of 2 years and over. The corresponding percentages for private engineering were 1.4 and 0.5 per cent.

For the separate fields of activity under private engineering, relatively the largest proportion of engineers under contract in their jobs occurred in manufacturing, with 408, or 3.8 per cent, of the 10,888 reporting as so engaged. In the construction and extractive industries 3.0 and 2.0 per cent, respectively, had written contracts. The smallest proportions under contract were reported by engineers in the employ of public utilities or engaged in transportation (1.1 and 0.9 per cent, respectively). In public engineering, there was a marked contrast in contract status between Federal positions and those in the 2 other categories of public engineering. Thus, while only 2.3 per cent of the 4,649 reporting engineers in Federal employ were on con-

2. Throughout the whole of this discussion, only engineering employment is considered. Consequently, no cognizance has been taken of the economic security of engineers engaged in nonengineering employment.

## Table III. Distribution of All Engineers Reporting Employment Contract, by Field of Employment at End of 1934

| Field of Employment | Number | | | | | | Per Cent | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Under Contract for— | | | Under Contract, No Period Reported | Not Reporting* | | Under Contract for— | | | Under Contract, No Period Reported | Not Reporting* |
| | Total | Under 1 Year | 1 and Under 2 Years | 2 Years and Over | | | Total | Under 1 Year | 1 and Under 2 Years | 2 Years and Over | | |
| All fields | 35,559 | 295 | 1,234 | 330 | 1,310 | 32,390 | 100.0 | 0.8 | 3.5 | 0.9 | 3.7 | 91.1 |
| Private engineering | 21,604 | 212 | 298 | 99 | 637 | 20,358 | 100.0 | 1.0 | 1.4 | 0.5 | 2.9 | 94.2 |
| Construction | 3,437 | 32 | 63 | 12 | 113 | 3,217 | 100.0 | 0.9 | 1.8 | 0.3 | 3.3 | 93.7 |
| Extractive industries | 1,841 | 11 | 21 | 6 | 60 | 1,743 | 100.0 | 0.6 | 1.1 | 0.3 | 3.3 | 94.7 |
| Public utilities | 4,183 | 16 | 21 | 8 | 50 | 4,088 | 100.0 | 0.4 | 0.5 | 0.2 | 1.2 | 97.7 |
| Transportation | 1,255 | 5 | 4 | 2 | 17 | 1,227 | 100.0 | 0.4 | 0.3 | 0.2 | 1.4 | 97.7 |
| Manufacturing | 10,888 | 148 | 189 | 71 | 397 | 10,083 | 100.0 | 1.4 | 1.7 | 0.7 | 3.6 | 92.6 |
| Public engineering | 11,177 | 53 | 224 | 121 | 295 | 10,484 | 100.0 | 0.5 | 2.0 | 1.1 | 2.6 | 93.8 |
| Federal Government | 4,649 | 33 | 42 | 34 | 181 | 4,359 | 100.0 | 0.7 | 0.9 | 0.7 | 3.9 | 93.8 |
| State and county governments | 4,438 | 15 | 125 | 50 | 81 | 4,167 | 100.0 | 0.3 | 2.8 | 1.1 | 1.8 | 94.0 |
| Municipal governments | 2,090 | 5 | 57 | 37 | 33 | 1,958 | 100.0 | 0.2 | 2.7 | 1.8 | 1.6 | 93.7 |
| Personal service | 2,778 | 30 | 712 | 110 | 378 | 1,548 | 100.0 | 1.1 | 25.6 | 4.0 | 13.6 | 55.7 |

* Also includes those who reported "no," which number could not be separated in the tabulation.

tract, the proportion working on this basis for state and county, and municipal governments formed, respectively, 4.2 and 4.7 per cent of their grand totals.

The type of work in which engineers under contract were engaged is presented in table IV. In general, the distribution followed the same trend as shown in table III, that is to say, the largest groups had written contracts for periods from 1 and under 2 years. Table IV also confirms the previous finding that engineers engaged in teaching are relatively more secure with regard to employment than other members of the engineering profession: 33.8 per cent of their number reported written contracts for periods of from 1 to 2 years. Sales employments, next in order, had under contract for a similar period only 3.9 per cent of their 1,513 reporting engineers, and general administration and management only 2.3 per cent. Each of the other functional classes had less than 2.0 per cent. Even for the contract periods of 2 years and over, teaching covered 4.8 per cent of the total reported for this functional class. The next highest percentage, namely, 1.5, was reported for general administration and management. In no one of the remaining employments did the percentage of engineers with written contracts for 2 years and over exceed 0.8 per cent.

Thus, with regard to fields of activity or the functional classes within them, the engineering profession cannot be said to have any substantial security of employment provided through a written contract for a period of time. However, professional engineers are not generally restricted with regard to the seeking of employment similar to that in which they may be engaged. This is evidenced by a consideration of the data furnished by professional engineers concerning their separation-contract status (tables V and VI).

Only 1.4 per cent of all the reporting engineers stated that they were under a contract for a definite period of time during which they bound themselves not to seek similar employment. This included 0.8 per cent whose separation contracts were for less than 1 year, 0.2 per cent for a period of from 1 to 2 years, and 0.4 per cent for 2 years and over. Clearly, restrictions upon professional engineers with regard to new employment were few.

It may be noted in table V, however, that 2.1 per cent of the reporting engineers in personal service were under separation contracts for less than one year, whereas the proportion in extractive industries and manufacturing was 1.0 per cent each. The reason for the relatively greater use of the separation contract in personal service is not clear. In extractive industries and manufacturing, the use of secret processes probably makes necessary some

## Table IV. Distribution of All Engineers Reporting Employment Contract, by Type of Work Engaged in at End of 1934

| Type of Work | Number | | | | | | Per Cent | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Federal Government | 4,649 | 16 | 1 | 2 | 8 | 4,622 | 100.0 | 0.3 | (†) | (†) | 0.2 | 99.5 |
| State and county governments | 4,438 | 27 | 1 | | 10 | 4,400 | 100.0 | 0.6 | (†) | | 0.2 | 99.2 |
| Municipal governments | 2,090 | 7 | 1 | | 8 | 2,074 | 100.0 | 0.3 | (†) | | 0.4 | 99.3 |
| Personal service | 2,778 | 57 | 7 | 2 | 31 | 2,681 | 100.0 | 2.1 | 0.3 | 0.1 | 0.1 | 96.4 |

* Also includes those who reported "no," which number could not be separated in the tabulation.
† Less than 1/10 of 1 per cent.

protection for the employer. It is evident, however, that even for these fields such a contract is seldom required. This freedom from restriction with regard to other employment is also apparent from table VI. Only 2 functional classes—teaching and sales—covered more than 1.0 per cent of their respective totals, and in neither did the period of contract exceed one year. In the teaching profession 2.5 per cent of the engineers were under separation contract and in sales 1.9 per cent; none of the other groups exceeded 0.8 per cent. Notwithstanding, it is significant that some 0.7 per cent of the engineers engaged in design and research were under separation contract for periods for 2 years and more.

### Provision for Retirement on Pension

An analysis of the data furnished by professional engineers concerning their pension privileges is presented in table VII. As of December 1934, 10,641, or almost 1/3, of the 35,559 professional engineers reporting who had engineering jobs at that time stated that they had pension privileges. Of this number, 6,684, or 18.8 per cent, were covered by contributory pension schemes, and 3,957, or 11.1 per cent by noncontributory schemes. Some 57.8 per cent were in employments for which no pension provision had been made. About 12.3 per cent did not furnish information.

Of the engineers in pensionable positions, the smallest relative proportion, 26.2 per cent, were engaged in private engineering. By contrast, 37.4 per cent of the engineers engaged in public engineering and 29.0 per cent of those in personal service had pension privileges. It may be noted also that for public engineering and personal service the contributory scheme predominated. Of the engineers engaged in private engineering, the largest proportion was covered by noncontributory systems. However, within the private-engineering group marked differences were shown; the same was true of the 3 categories of public engineering.

The largest number of professional engineers covered by a pension plan were those in the employ of the Federal Government. Out of a total employment of 4,649 engineers reporting, 43.2 per cent were under a contributory and only 5.3 per cent under a noncontributory plan. The corresponding proportions in positions with state and

## Table VI. Distribution of All Engineers Reporting Separation Contract, by Type of Work Engaged in at End of 1934

† Less than 1/10 of 1 per cent.

county, and municipal governments were very much less—26.9 and 1.3 per cent, respectively. For municipal-government employment the figures were 29.9 and 2.4 per cent. This order of difference parallels that of the proportions of engineers under civil service in these 3 classes of employment, but only in the case of the Federal Government are the 2 proportions closely related. This arises from the fact that, whereas all persons under Federal civil service must contribute to the retirement fund, this is not true to the same extent for employments under state and county, and municipal governments, where age, length of service, and salary are also taken into consideration.

Among the remaining fields of activity, public utilities and transportation reported the next highest proportions (after Federal employment) as having pension privileges. Public utilities and transportation used the noncontributory scheme; this type of plan covered 37.2 per cent in utilities and 33.1 per cent in transportation; contributory systems covered only 8.2 and 9.6 per cent, respectively, of those reporting. For the 3 remaining pursuits shown under private engineering, the largest number of engineers with pension privileges did not exceed 25.7 per cent, and in all cases contributory schemes predominated.

From the preceding discussion of the pension privileges it is quite evident that the kind of employment has a marked effect upon the question of the installation of a pension scheme. In no type of engineering employment was a majority of the reporting engineers protected by such a plan.

**Table VII. Distribution of All Engineers Reporting Pension Privileges, by Field of Employment at End of 1934**

| Field of Employment | Number | | | | | Per Cent | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | Pension Privilege | | | | | Pension Privilege | | |

## Patent Privileges in the Engineering Profession

Information as to patent privileges was furnished by 61.6 per cent of the 35,559 reporting engineers with engineering jobs at the end of 1934 (table VIII). Of all engineers covered, 31.7 per cent reported retention of the patent rights for all inventions made either in the course of their work or in fields not directly related to their work. Among the nine separate fields of employment this was true of the largest group in each case, except in manufacturing where the highest proportion (30.1 per cent) reported that they had no rights to patents relating to their work, but did retain their rights to those not directly related to their work. This latter combination ["(1) no; (2) yes," in table VIII] ranked second in importance and included 16.9 per cent of the 35,559 engineers. The third group in importance (including 4,575, or 12.9 per cent) was that reporting complete restriction on both aspects of patent privileges. Only 42 engineers, less than 0.1 per cent of the total, reported that they retained the rights to inventions connected with their duties but not to those not so connected.

It would seem that, comparatively, there is only slight restriction on the retention of patent rights among professional engineers, although its extent varies in the different fields of employment. Thus, relatively the greatest restriction was placed upon engineers engaged in manufacturing 19.0 per cent of whom reported complete restriction, 30.1 per cent the right to patent inventions not directly related to their work but not to those made in the course of their work, and only 23.1 per cent no restrictions. In the extractive industries the limitations, while less severe than in manufacturing, were nevertheless greater than in any of the other branches of private engineering. Complete restriction was reported by 15.6 per cent of the engineers in the extractive industries, by 11.8 per cent of those in construction, and by 11.4 per cent of those in transportation; the smallest proportion, 8.9 per cent, was reported for engineers in the employ of public utilities.

It has already been noted that in manufacturing, some 30.1 per cent of the engineers so engaged had the right to patent inventions not directly related to their work, but not to those made in the course of their work. This partial restriction was very much less for the remaining fields of activity in private engineering. In extractive industries, only 18.6 per cent so reported, in transportation 17.3 per cent, and in public utilities 16.0 per cent. Partial restriction affected only 8.6 per cent of the engineers engaged in construction. These same 4 fields of activity,

however, did report larger proportions as being unrestricted with regard to patent privileges. These ranged from 32.6 for extractive industries to 42.4 per cent for public utilities. In this regard, it may be recalled that only 23.1 per cent of the engineers in manufacturing so reported.

In the 3 classes of public engineering, there was a marked divergence in the restrictions placed upon patent privileges. This was greatest for engineers in the employ of the Federal Government, 12.2 per cent of whom had no patent privileges whatsoever, whereas in state and country, and municipal governments only some 9.0 per cent were under complete restriction. Partial restriction affected 12.5 per cent of the Federal Government engineers, but only about 5.5 per cent of those in the other 2 public employments. The greatest divergence occurred for those engineers who reported they had the right to patents made in the course of their work and also to those not directly related to their work. This group included only 21.7 per cent of Federal Government engineers, whereas

## Table VIII. Distribution of All Engineers Reporting Patent Rights, by Field of Employment

| Field of Employment | Total | Right Retained to Inventions (1) Made in the Course of Work, and (2) Not Directly Related to the Work: (1) Yes; (2) Yes | (1) Yes; (2) No | (1) No; (2) Yes | (1) No; (2) No | Not Reporting |

| Manufacturing | 100.0 | 23.1 | 0.1 | 30.1 | 19.0 | 27.7 |
| Public engineering | 100.0 | 30.1 | 0.1 | 8.5 | 10.3 | 51.0 |
| Federal Governments | 100.0 | 21.7 | 0.1 | 12.5 | 12.2 | 53.5 |
| State and county governments | 100.0 | 35.8 | 0.1 | 5.6 | 8.7 | 49.8 |
| Municipal governments | 100.0 | 36.7 | 0.1 | 5.5 | 9.4 | 48.3 |
| Personal service | 100.0 | 50.4 | 0.1 | 9.7 | 5.3 | 34.5 |

for state and county, and municipal governments the percentages reported were, respectively, 35.8 and 36.7.

Relative to all other fields of activity, the least restrictions were found in personal service, where 50.4 per cent reported unrestricted patent rights, 9.7 per cent partial restriction, and only 5.3 per cent no patent privileges. This freedom from restriction in the retention of patent rights for engineers in the personal-service group was due to the preponderance of teachers in this group, as examination of table IX shows.

Engineers engaged in teaching were under the least restriction as to the retention of patent rights, and

## Table IX. Distribution of All Engineers Reporting Patent Rights, by Type of Work Engaged in at End of 1934

| Sales | 100.0 | 29.9 | 0.1 | 20.5 | 19.4 | 30.1 |
| General administration and management | 100.0 | 33.6 | † | 16.0 | 12.1 | 38.3 |

† Less than 1/10 of 1 per cent.

engineers in design and research were under the greatest restriction. Of the 9,050 engineers classified as working in design and research, only 23.5 per cent had the right both to patents made in the course of their work and those not directly related to their work. As many as 55.3 per cent of the engineers engaged in the teaching of engineering subjects so reported. For the remaining 5 lines of work, the proportions with full rights to patents ranged from 29.9 per cent in sales to 33.6 per cent in general administration and management.

Relatively, the largest proportion of engineers who were partially restricted in regard to patent rights (26.6 per cent) was reported for design and research. Even in the case of sales, some 20.5 per cent were classified under this "no–yes" combination. By contrast, only 18.1 per cent of the engineers engaged in operation and 16.0 per cent in general administration and management were restricted only as to patents relating to their work. The corresponding proportions in construction, consulting, and teaching were very much less, ranging from 8.7 in construction to 9.7 in teaching.

The largest relative percentage completely restricted was 19.4—for the engineers engaged in sales—with design and research following next in order (15.8 per cent). From this point the proportion ranged downward to 13.4 per cent in operation, 12.1 per cent in general administration and management, 11.5 per cent in consulting, and 10.8 per cent in construction. The lowest percentage under complete restriction, namely 4.4, was noted in teaching.

# The Ultrahigh-Frequency Domain

By ALFRED N. GOLDSMITH
FELLOW AIEE

**Use of ultrahigh frequencies for educational broadcasting has been thought to offer attractive possibilities because of the supposedly almost unlimited number of channels; however, the demands of other radio services, particularly television, may be expected to congest this newly opened region. Ultrahigh-frequency waves behave somewhat like light waves, and give reliable and steady communication over short distances. The 6-megacycle band width required for television can be accommodated only in this region, but short range precludes, for the present, coverage of rural areas with these frequencies.**

THE ultrahigh-frequency waves have attracted considerable attention of late. It is but natural that educators have frequently considered the possible application of these waves for local educational broadcasting. In some quarters the optimistic thought has been expressed that in this new domain there will be space for the establishment of almost any number of local educational broadcasting stations. It will be attempted later in this presentation to analyze the probability of the successful execution of such a plan.

## Frequency Regions for Broadcasting

The radio waves referred to as lying in the "ultrahigh-frequency domain" are, broadly speaking, those having a wave length less than 10 meters. They result from electrical oscillations having frequencies greater than the extremely high value of 30,000,000 cycles or oscillations in each second. The waves in the existing broadcasting band—that is, the so-called "medium waves"—have lengths lying between about 200 and 550 meters, and correspond to electric oscillations of a frequency in the general neighborhood of 1,000,000 cycles per second. Lying between the medium waves for broadcasting and the ultrahigh-frequency domain are the short waves which are so effectively used, among other purposes, for trans-oceanic and transcontinental communication.

There is one additional region used for broadcasting, namely, that of the longer waves in the neighborhood of 1,500 meters, having a frequency of about 200,000 cycles per second. These waves are not used for broadcasting in America although they have had considerable application in Europe.

Thus there are, so to speak, 4 domains of possible interest for modern broadcasting. These are the long waves, having frequencies of the order of 200,000 cycles per second; the medium waves (so widely used in the United States), having frequencies of the general order of 1,000,000 cycles per second; the short waves, having frequencies of the order of 10,000,000 cycles per second; and, finally, the ultrashort waves, which have the ultrahigh frequencies of from 30,000,000 to several hundred million cycles per second or even more.

It was hinted that the short waves were not widely useful for national broadcasting. They do serve admirably to cover the great distances required to span oceans, but they give a relatively poor local service and create so considerable an amount of interference at distant points in other countries when they are used for primarily local broadcasting that it seems inappropriate to regard them as a proper means for completely carrying out national broadcasting in such countries as the United States.

Accordingly, so far as future expansion of the broadcasting realm is concerned, attention must be concentrated on the ultrahigh-frequency domain. The nature of these waves is worth considering more fully. To begin with, they are a good deal more like visible light than are the short, medium, or long radio waves hitherto used. By this is meant that these waves are more readily blocked by obstacles which would stop light; are reflected by objects somewhat like those which would reflect light; and have somewhat of the reliability and steadiness of transmission which light waves attain in the absence of fog or material obstacles.

## Ultrahigh-Frequency Transmission

Broadly considered, an ultrahigh-frequency transmitting station acts like a sort of radio lighthouse. Its rays travel outward in all directions toward the horizon and are best received along the "line of sight." For this reason it is common and approved practice to place the ultrahigh-frequency transmitting stations on the top of the tallest structure which may be available and also to place them, as nearly as practicable, in the center of the region which they are intended to serve. The higher the location of the transmitting station, the greater the range of satisfactory transmission.

It is true that the ultrahigh-frequency waves do not stop completely at the horizon but can be received, though with diminished strength and increased unsteadiness, at distances considerably beyond the optical horizon. It is also true that occasionally these waves may "fade" beyond their normal range, that is, fluctuate rapidly in their strength at the receiving station.

---

Essentially full text of an address presented at the First National Conference on Educational Broadcasting, Washington, D. C., December 10–12, 1936.

ALFRED N. GOLDSMITH is a consulting industrial engineer in New York, N. Y., and a Life Member of the AIEE. He received the degree of bachelor of science from the College of the City of New York, on the faculty of which he served for many years, the degree of doctor of philosophy from Columbia University, and, in 1935, the honorary degree of doctor of science from Lawrence College. Doctor Goldsmith is a past-president of the Institute of Radio Engineers and of the Society of Motion Picture Engineers, and is the author of many technical articles and books.

It has been reported that the occasional range of transmission and reception of the ultrahigh-frequency waves may be very considerable. Distances from 100 to several thousand miles have been cited in this connection. How frequently such extreme ranges may occur and upon what physical factors they depend are not yet known with certainty. Accordingly, a proper precaution is to suspend judgment as to the extent to which these facts will influence the allocation of the ultrahigh frequencies.

Nevertheless, taken by and large, the ultrahigh-frequency waves work best to distances little beyond the visible horizon, produce a steady and reliable signal with a minimum of distortion of the material transmitted (whether televisual or telephonic), and are relatively free from erratic changes in transmission. It is fair to state that, as a rule, the ultrahigh-frequency waves are transmitted with somewhat of the steadiness and constancy to be attained in a properly designed wire or cable system operating under the most favorable conditions.

Another fortunate aspect of the ultrahigh-frequency waves is the relatively low level of natural interference. It is well known that atmospheric electrical disturbances trouble radio listeners on the medium waves during the summer months, even in the northern portions of the United States. The ultrahigh-frequency waves, on the contrary, are little troubled from this source, though a number of man-made devices (such as the ignition systems of some automobiles and medical diathermal equipment) may cause serious interference with the reception of these waves at points near the outer limits of their service range. Fortunately automobile ignition systems can be shielded, and there is little doubt, should ultrahigh-frequency waves become widely used for broadcasting to the public, that the automobile industry will likely co-operate by taking such measures as will reduce ignition interference. Possibly diathermal outfits will be given their own assigned frequency, thus preventing most of the interference caused by them.

While the ultrahigh-frequency waves give reliable and steady communication, their service range, as indicated, is usually limited to distances of the order of several tens of miles from the transmitter. The questions will naturally be asked: Why should these waves be used in broadcasting? With their limited range what compensating advantages do they display? What can be accomplished by their use which cannot be otherwise accomplished? What broadcasting opportunities are thus offered? And what broadcasting methods, of special interest to educators, can thus be realized?

## Widths of Frequency Bands for Communication

Before answering these questions it is necessary to consider briefly the demands made upon radio transmission capabilities by the various forms of communication. The simplest form of communication is telegraphy—by dots and dashes. This requires a limited band of frequencies or "space in the air." Actually a few tens, or at most hundreds, of cycles per second are required next to one or both sides of the so-called carrier wave by telegraphic communication. Telephonic communication—the transmission of speech or music—makes more severe demands. In this case the frequency band required (that is, the so-called "side band") is about 10,000 cycles wide. The demands of facsimile communication—the transmission of drawings, printed text, writing, or photographs in the form of a record—requires perhaps a half or a third as much space for the corresponding frequency band as telephony. Then there is television, which is the most difficult of the communication arts. This is the transmission of pictures in motion, in transient form (that is, not recorded). The side band in this case rises in width to millions of cycles. For example, a side band about 2,500,000 cycles wide is believed to be required for really acceptable television pictures.

The difficulty of each of these methods of communication is somewhat proportionate to the side-band width required as previously indicated. This must not be taken too literally. However, it is fair to say that television is much more difficult than either telephony or facsimile which, in turn, exceed telegraphic communication in their technical requirements.

As hinted in the foregoing discussion, every transmission of intelligence by radio is accomplished by using a carrier wave for transmission and by modulating or controlling this carrier wave in such fashion as to convey the intelligence in question. The result of this modulation, in the simplest case, is to add new side bands on each side of a carrier wave; these side bands occupy frequencies to the exclusion of the interference-free reception of other communications of comparable strength on the same frequencies in the same general locality. (For the moment, the capabilities and advantages of directional reception are not under consideration.)

That television cannot be carried out, with adequate picture quality, on the medium broadcast waves becomes at once evident. Finding space on such waves, having an average frequency of a million cycles, for side bands several million cycles wide such as are required by television is not possible. It becomes necessary to go to the ultrahigh frequencies. If the carrier frequency has the ultrahigh value of say 50 megacycles there is obviously room on each side of this frequency for the side bands required by television, wide though such side bands be.

## Beam Transmission of Ultrahigh Frequencies

It is also desirable, before answering the questions which have been posed, to consider one other useful characteristic of the ultrahigh-frequency waves. These waves are quite short and are accordingly readily focused, if desired, so that they may be transmitted primarily in a given direction in a narrow beam. This is important whenever directional transmission and reception are required. A proposal has been made to use the ultrahigh-frequency waves for relay communications. In this process the transmission from a given station of these waves is picked up at a distant point by a corresponding receiving station, and the received signals are amplified powerfully by one means or another and then sent into a nearby second

transmitter which carries them along on their way to a further receiving station where the process of automatic relaying is carried out. Several such ultrahigh-frequency relay stations, each picking up its signal from the preceding and sending it forward along the relay system, would constitute a sort of network.

The difficulty experienced in using medium or long waves for the purpose of radio relaying involves the problem of efficient transmission and accurate reception. In this respect the ultrahigh-frequency waves are nearly ideal. They can be readily concentrated in a given direction toward the next relay station; and the amount of interference experienced in reception because of natural electrical disturbances is, as has previously been stated, relatively very slight and unimportant. For these reasons the ultrahigh-frequency waves lend themselves well to radio relay systems.

## Use of Ultrahigh Frequencies for Broadcasting

To some extent the questions which have been previously set forth can now be answered. First, as to the question: Why should the ultrahigh-frequency waves be used in broadcasting? The answer is that they show reduced distortion of quality, diminished interference from natural electrical disturbances, and a high degree of reliability of service within their normal range, which range is quite adequate to cover most urban and suburban areas or areas of corresponding size in rural regions. They require only reasonable amounts of power to accomplish such results provided the transmitting station is centrally located on the top of a high structure. Under usual conditions these waves do not cause severe distant interference and have only a limited "nuisance range," in contradistinction to the short and medium waves which sometimes cause interference at distances far beyond their range of useful reception. Further, the fact that the utilization of these waves might, if judiciously carried out and with due control, somewhat relieve the worst congestion now existing on the medium broadcasting waves cannot be overlooked. In the foregoing statement it is believed that there has similarly been answered the question: With their limited range what compensating advantages do they display?

The next question is: What can be accomplished by their use which cannot otherwise be accomplished? Through the use of ultrahigh-frequency waves it is possible to have more local stations which would be substantially noninterfering than would be the case if the medium waves were used. It is possible to establish more nearly constant day and night quality of service than is now the case. It is also feasible to maintain winter and summer reception on more nearly the same level of freedom from natural electrical disturbances. While it is true that man-made devices, such as automobile ignition systems and medical diathermal equipment, can interfere with ultrahigh-frequency reception, yet the reduction of such types of interference by organized planning, regulation, and industrial co-ordination offers greater possibilities than the elimination of natural disturbances—which latter have proved extremely stubborn as to their elimination by any methods of conventional sort requiring no increased width of frequency band for the corresponding transmission and reception. By the use of the ultrahigh-frequency waves it becomes at once possible to transmit telephone programs (that is, speech and music) on an extremely high-fidelity basis and, similarly, to receive these programs with such accuracy of reproduction in the home as will greatly enhance the clarity of speech and the naturalness of reproduction of music. Present-day broadcasting on the medium waves is greatly handicapped in its struggle to obtain high fidelity transmission and reception by the congestion of stations on neighboring channels only 10,000 cycles (10 kilocycles) apart. Actually 3 times this separation could be used to advantage were it available—which it emphatically is not in a country like the United States where great areas must be covered, where numerous broadcasters insist on the privilege of transmission, and where occasionally political considerations may be urged in connection with the allocation of transmission frequencies. Broadly stated, more reliable local transmission, less interference from natural disturbances, a partial relief from certain types of congestion of transmission facilities, high-fidelity telephonic operation, and a steady and reasonably uniform all-day and all-year service can be anticipated from the ultrahigh frequencies.

## Use of Ultrahigh Frequencies for Television

Perhaps the greatest opportunity offered by the ultrahigh-frequency waves, namely, the introduction of television, has not as yet been analyzed. Here is one service, at least, which could not conceivably be carried out according to present knowledge on any but the ultrahigh-frequencies. Its side-band demands for an extraordinarily wide band of frequencies can be met only in this new domain. Since the visual services can reasonably be expected to add a great deal to the value of broadcasting as an educational medium in the broadest sense, there is no question but that the ultrahigh frequencies will find a wide and successful application for that purpose.

Only very recently was reasonably good agreement reached among experts as to what constitutes an acceptable type of television. In a broad way the television picture is described as having "a certain number of lines," the lines being the parallel and adjacent paths over which moves the spot of light that creates the television picture. Initially as few as 24 lines were suggested for an acceptable television picture. Actually such a picture would be of the utmost crudity and capable of giving an extremely rough impression of only the simplest objects. As time went on, 45-line pictures and then 60-line pictures were proposed. In each case the almost pitiful inadequacy of such television pictures, so far as any educational or entertainment value was concerned, became fully evident. There then followed attempts to use 120 and 180 lines of television pictures and, for the first time, a slightly useful television picture was produced. However, present-day experimental practice here and abroad involves pictures having 343 lines or 405 lines, respectively (although some

attempts are still made to use 240-line pictures). The proposed standard for the United States is a 441-line picture. At its best such a picture may be described, crudely enough, as definitely better than a projected motion picture from 8-millimeter film and perhaps nearly or quite as good as a motion picture projected from 16-millimeter film. The television standards so far proposed as practicable cannot be expected to give results equal to those obtained in an auditorium, for example, by the projection of 35-millimeter film. The pictures are monochrome—that is, essentially in black and white. Practical color television is a rather remote possibility and hardly one with which to be concerned for some time to come.

If television pictures having numbers of lines of between 300 and 500 are taken as a reasonable standard for the present, the side bands required for the corresponding transmissions are found to be extraordinarily wide as compared to those used for telephony. The proposed width for the side bands in the American television transmissions will be about 2,500,000 cycles per second. Only in the ultrahigh-frequency domain of waves can be found a practicable resting place for such transmissions. Accordingly television must necessarily embrace the capabilities and accept the limitations which have been previously described as associated with ultrahigh-frequency transmission and reception.

The establishment of a television transmitting station on the highest location in the region which is to be served is, nevertheless, unlikely to enable coverage over a range of more than a few tens of miles in each direction. While this is entirely adequate for most cities and their suburbs, it is certainly not adequate for the coverage of large rural areas where the concentration of lookers will be small and the distances to be covered will be great.

It may be judged from this that methods should be found, if possible, to give to television services an adequate rural coverage although it must be admitted that, up to the present, the problem of so doing is formidable both technically and economically. One may also conclude that the medium-frequency telephone broadcasting stations of today, while unable to render television service because of the limitations of medium-frequency transmission as pointed out previously, will nevertheless necessarily remain the backbone, so to speak, of the broadcasting structure in so vast a country as the United States, at least for many years to come. From this the comforting thought may be extracted that the present broadcasters do not face an abrupt obsolescence of their stations which, so far as can now be told, will still render a useful rural service in the future. No present means of replacing the rural service in question by technically correct and economically feasible utilization of ultrahigh-frequency transmissions is known. However, even these problems may in time be solved to the advantage of ultrahigh-frequency methods.

## Facsimile Broadcasting

Facsimile broadcasting is perhaps of particular interest to the educator since it is the only form of broadcasting which offers a permanent record of textual and graphic material. It is a sort of radio printing press located in the home and capable of producing pages (and even books, if given reasonable time). Facsimile broadcasting could technically be carried out on the existing broadcast frequencies, that is, the medium frequencies. The side bands required are little different from those necessary for telephony. However, the congestion in the present broadcasting band is so extreme that it would be out of the question at this time to add other services in the present broadcasting band. The interesting suggestion has been made that facsimile broadcasting might be carried out during the early morning hours on the existing broadcasting band, the reproduced material on sheets of paper being available to the recipient as he awakens in the morning. Such a service has distinct limitations and would likely be useful, if at all, only during an interim stage of development and as a facsimile service to rural areas not readily reached by ultrahigh-frequency transmissions.

If more or less continuous facsimile broadcasting is to be established in urban and suburban areas, it is more logical to expect that it will be associated with its related visual service—television. That is, facsimile broadcasting also finds a natural location in the ultrahigh-frequency domain. It must be left to the imagination of the educator to envisage the numerous attractive possibilities of instruction and examination which are afforded by this type of broadcasting. However, the limitations of range of the ultrahigh-frequency waves must be kept in mind here, as well as in the case of television broadcasting.

## Availability of Channels in the Ultrahigh-Frequency Domain

The likelihood of the successful establishment of a substantially unlimited number of ultrahigh-frequency educational stations for local broadcasting in a given neighborhood can now be analyzed. The television experts have reached the conclusion that the television-telephone channels must, for effective picture and sound transmission, be about 6,000,000 cycles (6 megacycles) wide. In studying television standards the committee on television of the Radio Manufacturers Association has proposed the use of the frequencies between 42 and 90 megacycles for television transmission (excluding the amateur band between 56 and 60 megacycles). In view of the impression which may exist that an indefinitely large number of television transmissions can be placed within this region it is interesting to know that there are only 7 available channels, each 6 megacycles wide, in this whole requested band of frequencies! Where 2 cities, like New York and Philadelphia, are about 100 miles apart, it is possible that television allocations would be so restricted as to provide say 4 television transmissions for New York City and 3 for Philadelphia. Otherwise stated—and this is a rather startling and discouraging fact—there appears to be space at this time in the ultrahigh-frequency domain for fewer television-telephone transmissions in a given locality than there is space for the usual telephone broadcasting channels in the existing medium-frequency band. Accordingly,

until even higher frequencies than 100 megacycles are available for satisfactory broadcasting of telephone, television, or facsimile material, it is unlikely that the average city can enjoy the privilege of simultaneous operation of more than a limited number of television-telephone transmissions. It has been the unhappy experience in radio broadcasting that the opening of a new domain always appeared to offer an almost limitless opportunity for simultaneous and noninterfering transmissions but, after practical examination and test, it has turned out to offer extremely few opportunities in comparison with the number anticipated. In fact, no radio domain so far rendered available has, after a reasonable time of development, been free from marked congestion at some time. Unfortunately there is no present reason for believing that the ultrahigh-frequency domain will be an exception to this experience of the past, and whatever congestion now exists in broadcasting may be expected to continue when the ultrahigh-frequency waves are used.

It would probably be good counsel to the educators of the United States to advise them to keep fully informed on the technical and industrial developments in the ultra-high-frequency domain and to study carefully in advance what may probably be accomplished by the use of the radio and visual broadcasting services which can be established in this domain. It would also be well if carefully planned broadcasting of educational material were carried out, using these new frequencies and the novel forms of transmission, such as facsimile and television, which they render possible. However, if education is to derive its full benefit from these new instrumentalities of science, it will involve much sober thought, co-operative effort, and systematic planning on the part of educators. The field is too complex and its problems too numerous to make an unplanned success at all probable or to reward casual, meager, or purely selfish efforts.

Beyond a doubt, engineers will do their utmost to perfect the approaching art of television and facsimile broadcasting and of telephone broadcasting as well, all on the ultrahigh frequencies. It is hoped that the educators of America, fully awakened to the interesting civic possibilities which these communication media offer, will similarly avail themselves of their potentialities systematically and effectively.

## Practical Limitations of
# The Broadcast Allocation Structure

By C. B. JOLLIFFE
MEMBER AIEE

**To give the radiobroadcast listener maximum service is an important problem in which the frequencies available, characteristics of the receiving set, phenomena of transmission of radio waves, area to be served, and density of population in the area must be considered. Broadcast stations in the United States are of 2 main classes, clear channel and duplicated channel, and are allocated in frequency to prevent interference between stations in the same area. Short-wave broadcasting has additional limitations because of natural phenomena.**

BROADCASTING, as it is known today, is a newcomer in radio communication. Consequently, since its start in 1921 when a single frequency was made available for the service, radiobroadcasting has had to make its own place in the radio spectrum purely on the basis of public interest and public acceptance. It has been estimated that at the end of 1936 approximately 30,000,000 radio receiving sets were in use in the United States. This alone is ample proof that the public has accepted broadcasting. If nothing else were considered, the huge investment of the public in this industry is sufficient to give broadcasting a position of commanding importance. Because of its great importance to the public, a thorough understanding of the underlying principles of broadcast allocation is necessary in order to judge the effectiveness of any allocation or in order to make constructive suggestions concerning improvements.

In the frequency spectrum, broadcasting of the United States has been allocated the space from 550 to 1,600 kilocycles for domestic service and several frequency bands between 6,000 and 22,000 kilocycles (6,000–6,150; 9,500–9,600; 11,700–11,900; 15,100–15,350; 17,750–17,800; 21,450–21,550) for international service. This discussion will be limited to these bands of frequencies.

Essentially full text of an address presented at the First National Conference on Educational Broadcasting, Washington, D. C., December 10–12, 1936.

C. B. JOLLIFFE is engineer in charge of frequency bureau, Radio Corporation of America, New York, N. Y., and is chairman of the AIEE committee on communication. He received the degrees of bachelor of science and master of science from West Virginia University and the degree of doctor of philosophy from Cornell University. From 1922 to 1930 he was associate physicist in the Bureau of Standards, Washington, D. C., and from 1930 to 1935 was chief engineer of the Federal Radio Commission and its successor, the Federal Communications Commission. Doctor Jolliffe has served as delegate or technical adviser for several international radio conferences.

In the band from 550 to 1,600 kilocycles the principles of broadcast allocation have become fairly definitely stabilized. However, the average listener who tunes across the dial of his receiving set may well wonder if there is system and order behind what he hears. Why is he able to receive on some points of the dial while at other points he hears a mixture of signals from many stations? Why is not every point or every channel on the radio dial available to give him perfect service? What should a listener expect to hear on his receiving set? The answers to these questions are not immediately obvious, but the answers are relatively simple when one studies the bases of allocation used in the United States and the severe limitations imposed on the allocation of frequencies to broadcast stations. It is the purpose of this article to discuss these limitations of broadcast allocation and give a brief picture of the structure under which the broadcasting industry operates at the present time.

## Medium-Frequency Broadcasting Service

### Number of Frequency Channels Available

The fundamental limitation to every radio service is the frequency space available for that service. All the radio communication services of the world work in a common transmission medium referred to as the ether. Radio waves of all frequencies can exist in this medium and retain their separate identities, that is, there is no mutual interference between radio waves in space. There is projected into this medium all types of signals—point-to-point telegraph communications, telephone communications, communication between police cars and headquarters, military communications, communication between amateurs, ship to shore telegraph and telephone, and so forth. If a receiving set which had no frequency discrimination were used, all these communications would be heard simultaneously as a jumble. Fortunately, receiving sets can discriminate with respect to frequencies and it is possible to pick out one band of frequencies and reject all others.

Consequently, it is necessary first to arrange the various kinds of communications in different frequency bands in such a way that receiving sets can pick out the band desired. Different groups of frequencies are assigned for use by different services and receiving sets are used which are designed to accept frequencies of a particular service.

At international conferences in which all nations of the world participate, the common communication medium has been carved into frequency bands which have been allocated to various classes of services.* Broadcasting has been allocated frequency space which the nations of the world believe to be its proportionate share of these frequencies. In North America there has been allocated the band of frequencies from 550 to 1,500 kilocycles for the exclusive use of broadcasting for the purpose of providing domestic broadcast service as it is known today. Because no interference to other parts of the world will be caused, the nations of North America have further agreed to use the space from 1,500 to 1,600 kilocycles for broadcasting. Similarly, the nations of Europe have agreed among themselves to use other frequencies (below 400 kilocycles) for broadcasting which do not cause interference in North America. The agreements concerning use of frequencies have been made by the duly accredited representatives of all nations of the world, including the United States, and are a part of the fundamental law.

The United States, then, has one of the pieces of the frequency spectrum, 550–1,600 kilocycles, available for broadcasting. The size of this piece is not likely to be changed. The duty of the Federal Communications Commission, which is the agency of the government charged with the administration of the radio laws and the assignment of frequencies to stations, is to assign frequencies in this space to broadcast stations in such a manner as to provide the best broadcast service possible to the people of the United States.

The Commission has decided that stations will be allocated at intervals of 10 kilocycles through the space 550–1,500 kilocycles. This provides, then, using channels at both ends of a block of frequencies, 96 channels of communication for use in North America. Assuming that the frequency space from 1,500 to 1,600 kilocycles will be assigned eventually on the same basis, 10 more channels may be added, making a total of 106 for use by broadcast stations in this band. By agreement between the United States and Canada, 6 frequencies have been allocated for the exclusive use of the latter. Thus a total of 100 channels remains for use by stations of the United States. This then is the first limitation of broadcast allocation.

### Performance of Receiving Set

The radio receiving set used by the listener constitutes the second limitation on allocation. Broadcast stations are assigned at intervals of 10 kilocycles. In order to have satisfactory radio reception it is necessary that but one program be reproduced in the output of the receiving set. The antenna which is used to pick up a minute amount of power from the transmission medium has flowing in it currents of all frequencies produced by transmitting stations of corresponding frequencies. The function of the receiving set is to pick out, amplify, and reproduce the currents produced by the one transmitting station desired and reject all others.† If 2 transmitting stations separated by 10 kilocycles produce in the receiving antenna approximately equal currents, most receiving sets can receive one station and reject the other. If the 2 stations are separated by 20 kilocycles the unwanted station can be approximately 20 times the strength of the wanted station and the receiving set can select one from the other. If the ratio is greater than this then the average receiving set cannot make a clear distinction This ability of the receiving set to accept one station and reject another is referred to as the selectivity of the receiving set, and is the factor which makes possible the

* Article 7, General Radio Regulations annexed to the International Telecommunication Convention, Madrid, 1932, Treaty Series No. 867.

† "Characteristics of American Broadcast Receivers as Related to the Power and Frequency of Transmitters," Arthur Van Dyck and D. E. Foster. IRE *Proceedings*, volume 25, April 1937, page 387.

operation of many stations at the same time.

Some may remember in the early days of broadcasting that reception of one station without at the same time receiving signals from several other stations was extremely difficult. The development of the modern receiving set has been one of increasing its selectivity and approaching that ideal by which it is possible to accept one signal and reject all others regardless of their intensity.

Technical limitations make impossible the complete accomplishment of the ideal in the present state of the art. It is sufficient to state that with the present development it is possible to receive a signal on a given frequency and reject all others separated by 50 kilocycles or more regardless of their intensity. At less frequency separation than 50 kilocycles with modern receivers rejection of adjacent frequencies is possible provided they do not exceed certain values, the value which may be present decreasing as the frequency separation decreases.

A modern receiving set is a marvel of ingenuity which is accepted and used with little thought of the amount of work which has gone into its design and production. It is the best that engineers have been able to design and produce at a cost which can be borne by the listener. It does, however, represent the second limitation in allocation.

## Transmission of Radio Waves

The third limitation is the most fundamental and one which is imposed by nature; that is, the ability of radio waves once radiated to travel through space. When an alternating current of high frequency flows in an elevated conductor there is set up around it an electromagnetic field which moves through space with the speed of light. Variations in the intensity of the current flowing in the conductor produce similar variations in the electromagnetic field which make it possible for these electromagnetic waves to carry a message through space. Once these electromagnetic waves have left the antenna there is nothing which man has conceived to date that can be done to alter their course. The intensity of these waves at any given point is proportional to the amount of current flowing in the elevated conductor or antenna, and falls off rapidly as the distance between the antenna and the receiving point is increased.

At night a further complication is introduced. There is no simple transmission along the ground. The waves which leave the antenna at an angle from the ground and which in the daytime are usually lost in space, at night encounter what appears to be an electrical mirror at a height of some 50 to 100 miles above the surface of the earth. This electrical mirror returns the waves to earth and they are then capable of producing currents in the antenna of the receiving set even though the distance be very great.

This electrical mirror is not uniform and the waves which return are consequently not of uniform intensity. This gives rise to the phenomenon which has been called "fading." There are 2 types, one of which is produced when the reflected wave and the wave that is propagated along the ground both are of sufficient intensity to produce currents in the antenna. These waves having arrived over different distances and being of different phase interfere with each other and produce variations in the current produced in the receiving antenna. Irregularities in the reflecting medium vary the intensity and phase of the reflected wave while the intensity of the ground wave remains constant. This is the first type of fading which is encountered as one proceeds from the transmitting station. This fading is usually quite severe and one of its characteristics is that it is selective so that certain parts of the speech or music may cancel out entirely and other parts remain or are augmented. This results in severe distortion and very unsatisfactory reception. There is no known practical remedy for this type of fading and it is the limit of good service of many broadcast stations.

Beyond this region of interference between "ground" and "sky" wave the sky wave predominates and fading is due to irregularities in the reflection of the waves. This fading, the second of the 2 types, is usually not selective and all portions of the program change equally. This type of fading is substantially corrected by the modern receiving set by means of automatic control of the amount of amplification used by means of the intensity of the incoming signal.

The phenomenon of transmission of radio waves is extremely complex and in order to understand the laws governing it a large amount of experimental data must be obtained. These data have been accumulated over a period of years and it is believed that what to expect under any given set of circumstances is now known. The laws governing these transmissions are as exact and as certain to operate as the laws of gravitation. Man cannot alter them, he can only learn the fundamental bases and adapt himself to these bases. He may be able to apply apparatus and equipment which make better use of the transmitted signal, but he must always recognize that nature has set this limitation.

A corollary to this limitation of transmission is that of interference. When 2 radio waves of approximately the same frequency exist simultaneously in space they will produce in the antenna of the receiving set alternating currents of approximately the same frequency. The receiving set which depends on differences in frequency in order to select between 2 stations can make no selection when the frequencies it receives are the same. Consequently the signals carried by both radio waves will produce signals in the output of the receiving set. In order that one signal may be heard above the other it must be of sufficient strength that it can completely mask the other so that the receiving set appears to reproduce only one signal; in short, a shout drowns out a whisper.

Nature is also a broadcaster and produces radio waves which travel through space as do other radio waves. Every discharge of electricity in the form of a spark sets up electromagnetic waves. The noise produced by thunderstorms, which is usually referred to as static or atmospherics is familiar to all. The general accumulation of electrical discharges in space between clouds and between clouds and ground sets up a background of radio noise which

is picked up by the receiving antenna. Added to this there are the spark discharges produced in all types of electrical apparatus such as motors, generators, and flashing signs. This group of transmitters produces radio noise which is usually referred to as background noise. It is always present in a greater or lesser degree. In highly congested centers of population the background noise produced by electrical machinery may be extremely high while in a rural section with little electrification it may be practically zero. The natural noise produced by natural discharges is usually very high in the summer, particularly in the tropics, and practically nothing in the winter. The minimum amount of signal considered necessary to render good service under varying conditions is a measure of the amount of noise present on the average.

### Area and Distribution of Population

The final limitation of allocation is the size of the United States and the distribution of its population. The population of the United States is distributed over an area of approximately a rectangle 3,000 by 1,500 miles. The distribution of population varies from many thousands per square mile in highly concentrated centers of population to an average of less than one per square mile in wide open spaces. The time at which people are listening to broadcast programs varies, depending on time zones and habits of the various classes of people. It is not possible to change these factors, but it is possible to know what they are and act accordingly.

These are the technical limitations. None of them has been gone into exhaustively in this paper; any one of them is a subject for a paper itself. When broadcasting started there was little information available. As broadcasting has developed it has developed its instruments and measurements and accumulated its data. That which it is necessary to know concerning all of these limitations may be said now to be known. They can be analyzed and used in building and improving an allocation structure. They cannot be ignored simply because what they produce is not liked. Legislation and regulation may dictate or limit how these principles can be applied but they cannot change the fundamental technical laws.

### Plan of Allocation

How these limitations have been recognized and applied may now be briefly considered. That these applications are the only methods which might be used is not inferred, but they are used as illustrations of what has been done and what is familiar to everyone.

Stations of the United States have been classified into 2 different main classes: stations operating on clear channels, that is, one station only permitted to operate at night using the maximum amount of power; and stations operating on duplicated channels, that is, 2 stations or more permitted to operate simultaneously on each channel.

Stations of different classifications are distributed throughout the United States in such a manner that stations operating on adjacent frequencies are separated geographically from each other, thus recognizing the limitation in selectivity of the receiving sets. So when a listener is near one station, stations on channels 10, 20, 30, and 40 kilocycles removed therefrom are at distances from the listener so that the signals from them should always be below the values necessary to cause interference to the nearby station.

The Commission and station operators have recognized that the service area of a station is of 2 kinds, primary service and secondary service. The primary service is that area in which all listeners get service free of interference. The secondary area is that area in which the listeners get some amount of satisfactory service, but which is not always free of interference. For clear channel stations the primary area may extend for 100 to 150 miles up to the point of severe and selective fading. Beyond this area of severe and selective fading there exists a secondary area which extends to the limit of useful signal produced by the station. This useful limit of the secondary area is fixed by the amount of natural noise and consequently changes from day to day and season to season.

It should not be expected that everywhere within this secondary area there is freedom from interference and that the whole of the United States is within the secondary area of every clear channel. The limitation of radio-wave propagation limits the distance for which it will be useful. Also, the strength of signals from stations on adjacent frequencies will make the signal of no use in certain areas. If the secondary area of a clear channel station were charted it would consist of a map of the United States with many areas removed, the amount removed depending on the location of the stations on adjacent channels and the noise intensities in various areas.

Stations which operate on duplicated channels have their night service area limited by interference from the other stations operating on the same channel. At night these stations have very little, if any, secondary service and their primary service can be very accurately defined; in fact, so accurately defined that its use as a basis for estimating the number of people who can be served by the station is possible.

A station operating on a duplicated channel, therefore, is used to serve a center of population and is not expected to have any service at night beyond its normal service area limited by interference from other stations on the same channel.

The result of the allocation is, therefore, that clear channel stations serve centers of population with primary service up to the beginning of fading and then have a very extended secondary area, and stations operating on duplicated channels serve centers of population but have no secondary service, the entire service lying within an area relatively close to the station.

### Service Received by the Listener

From the listener's standpoint, then, if he lives in the good service area of either a clear-channel station or a station operating on a duplicated channel, he should obtain excellent service free of interference from these stations. In addition he should be able to receive the secondary service from many of the clear channel stations. This secondary service is usually less satisfactory than the pri-

mary service from a local station. However, program content may cause him to listen to a less satisfactory signal rather than his local signal free of interference.

Turning now to the questions which were asked in opening this paper, the answer is that the distribution of population over the United States, and consequently distribution of radio stations, makes it necessary that persons in some localities be deprived of service on certain channels in order that persons in other localities can have primary service. If, for example, the people of Washington, D. C., had perfect service on all 100 channels then the people in all cities beyond approximately 100 miles from Washington, D. C., would have to depend entirely on secondary service. This example can be carried to any center of population.

A person in a given locality should be able to hear all the stations which have their primary service area covering his locality, plus the secondary service from clear channels. Persons who do not live in a center of population having local service must depend entirely on the secondary service from clear channel stations. On duplicated channels on which no station gives primary service in his area he will simply hear a mixture of signals. These channels are giving primary service to other areas.

## High-Frequency Broadcast Service

The limitations and use of the frequencies used for international broadcasting, that is, frequencies between 6,000 and 22,000 kilocycles may now be discussed very briefly. These frequencies by their very nature are capable of world-wide interference and a type of world-wide service. In the frequency band above 6,000 kilocycles practically all of the radio commerce of the world is carried; communication between ship and shore, between the United States and all other countries of the world, and among the other countries of the world. This communication service puts a severe load on the frequency spectrum. Because of this large load of commercial traffic only a very small portion of the frequency spectrum has been allotted to broadcasting.

The transmission characteristics of these frequencies change very markedly as the frequency range is changed, as the transmission path changes from daylight to dark, and as the seasons change. These characteristics are well known.

A frequency of the order of 15,000 kilocycles for example, used for transmission from a station produces very little service in its immediate neighborhood, but does produce in the daytime a very strong signal at distances of greater than approximately 1,000 miles away. In other words, if an observer were to travel out from a station with a receiving set he would find that its service fell off very rapidly in the first few miles, then disappeared for several hundred miles, and then began to reappear again. This distance in which the signal vanishes is called the "skip" distances for that frequency. Skip distance varies from a few miles for the lower frequencies in the daytime to thousands of miles for the higher frequencies at night. In fact, frequencies above approximately 10,000 kilocycles are useless at night because their skip distance is greater than half way around the world. Because of this characteristic of transmission, in order to serve a particular point or a particular area at a distance from the station, it is necessary to use a different frequency in the daytime than at night and also a different frequency in winter than is used in summer. Consequently, to permit continuous service to be given to a country, such as Argentina in South America, would require from 3 to 5 frequencies spaced properly between 6,000 and 20,000 kilocycles, the proper frequency being used in accordance with its known propagation characteristics.

It has been suggested that these frequencies be used for the purpose of covering portions of the United States. In order to do this each station would be required to use from 3 to 5 different frequencies throughout the period of propagation in order to cover given areas. If each country in the world tried to give this kind of a service it would require more than all the frequencies above 6,000 kilocycles to meet the needs of all nations. Instead of a station being assigned a single frequency, as is done in domestic broadcasting, each station would have to be assigned a multiplicity of frequencies, and instead of the allocation problem being confined to the United States, the interference limitations imposed by stations of the entire world would need to be met.

The nations of the world, realizing this lack of adequate supply of frequencies, have practically all confined their use of these frequencies to broadcast programs destined for reception in other countries. Unfortunately, this has not been confined to the propagation of entertainment programs only, but these programs have also included propaganda and much might be said as to the improper use of such frequencies. However, this is not a technical question.

These frequencies likewise have the same limitations with respect to fading as do the lower frequencies used in broadcasting. The entire service of these frequencies is secondary service and consequently subject to fading and interference from electrical noises. The service can never be as good as the service given by a steady signal from a local station. The limitations of selectivity of receiving sets and distribution of population also apply to this band of frequencies.

From an engineering standpoint it is known what these frequencies can do and what limitations they have. The limitations are natural phenomena and there is nothing that can be done to change the phenomena. By technical advances the characteristics of the devices which transmit and receive them, may be changed but at present there appears no way by which the laws of nature can be changed. With these frequencies, as with the broadcast frequencies, the utmost information concerning the laws of nature must be obtained and applied to the best of our ability to the problems in hand.

Man may not like the consequences of natural laws and the natural limitations of radio propagation, but he must accept them. Man can make and unmake his own laws and limitations, and change them as he desires, but nature makes her laws and they are final; man can learn what they are and use them, but he cannot change them.

# The Dielectric Strength of Noninflammable Synthetic Insulating Oils

By F. M. CLARK
ASSOCIATE AIEE

THE SUBSTITUTION of chlorine for hydrogen in the hydrocarbon molecule produces marked effect not only on the physical and chemical properties, but on the electrical characteristics as well. The compounds so produced present to the electrical engineer a new type of insulating liquid which eliminates many of the problems heretofore inevitably associated with the use of mineral oil. It is the object of this paper to demonstrate the dielectric strength characteristics of such synthetic liquids both alone and in combination with cellulosic insulation.

Although the use of chlorine-containing compounds in the electrical industry is not new, the application of such liquid materials has been limited because of chemical instability. Under the conditions of voltage stress and high temperature normally encountered in the service of transformers, capacitors, cables, and the like, compounds of the chlorinated paraffin hydrocarbon type have not been found to be very satisfactory. With the development of the chlorinated liquid compounds of the cyclic hydrocarbons,[1,2] dielectric compositions have been made available which fully meet the stability requirements. Because of the desire to obtain noninflammability of the liquid as well as to eliminate the explosiveness of the arc-formed gases, the compounds of this type have at least half of the hydrogen atoms present in the original hydrocarbon replaced by chlorine.[3] Only such compounds are discussed in the present paper.

## The General Characteristics of Noninflammable Synthetic Insulating Liquids

The noninflammable synthetic dielectric liquids at present commercially available are, in general, chlorinated derivatives of cyclic organic hydrocarbons. In order to obtain suitable physical characteristics, such as viscosity and low congealing point, blends of chlorinated organic compounds are frequently employed. Among the compounds in commercial use or available for use are the chlorinated derivatives of diphenyl, diphenyl oxide, benzophenone, diphenyl methane, dibenzyl, and benzene. Each of these has its advantages.[4] At present, however, the chief commercial interest lies in compositions containing chlorinated diphenyl and mixtures of chlorinated diphenyl with trichlorbenzene. The properties of 2 such compositions in commercial use as impregnants for capacitors and cables, and as the dielectric and cooling medium for transformers are given in table I. Such compositions are not only noninflammable in themselves, but when decomposed by the electric arc evolve only noninflammable gaseous mixtures.

## The Dielectric Strength of the Liquids

The factors which determine the dielectric strength of insulating liquids are not clearly recognized. Liquid density is without doubt of importance in any homologous series of organic compounds. The difference in density as between two different chemical types of organic liquids, however, does not appear to be of significance in determining the relative dielectric strengths. It has been suggested[5] that the dielectric strength of mineral oils varies with those changes which produce a variation in the dissolved gas content of the liquid. Such a suggestion does not attempt to explain the high dielectric strength of the noninflammable synthetic dielectric liquids described in table I as compared to mineral oil of similar viscosity.

While it is recognized that the dielectric strength of any insulating liquid is distinctly a function of the care used in its preparation and test, the normally expected value for new and unoxidized mineral oil, tested in accordance with the usual practice, is about 30 kv at room temperature. The synthetic liquid dielectrics of table I tested under similar conditions are characterized by a dielectric strength which is from 40 to 50 per cent higher. Such a high dielectric strength becomes only of academic interest unless it can be maintained at a correspondingly higher than oil value during use. Accumulated service and laboratory experience clearly indicates such behavior.

Consideration of the dielectric adaptability of a liquid for any specific application must inevitably include a survey of its chemistry.[8] Detailed chemical analysis of the noninflammable synthetic dielectrics is beyond the scope of this paper, yet for the proper understanding of the materials, consideration of their chemical reactivity cannot be avoided. One of the major factors leading to decreased dielectric strength in liquids is the presence of moisture, moist fibers, gas bubbles, and suspended solids. It is unfortunate that in most of the dielectric applications of mineral oils, oxidation cannot be entirely eliminated. The oxidation of the oil hydrocarbon produces those types of materials which lead to decreased dielectric strength, as for example carbon dioxide gas, water, organic acids, and, if the oxidation is severe, suspended oil sludge. Water coming in contact with oxidized mineral oil may even form a semipermanent emulsion with dangerously low dielectric strength. The noninflammable synthetic

A paper recommended for publication by the AIEE committee on research. Manuscript submitted March 20, 1937; released for publication April 27, 1937.

**Table I. Properties of Noninflammable Synthetic Liquid Dielectrics**

| Type | Viscous | Nonviscous |
|---|---|---|
| Use | Capacitors and cables | Transformers |
| Color | Pale yellow | Pale yellow |
| Specific gravity | 1.500 (60/15.5 degrees centigrade) | 1.565 (15.5/15.5 degrees centigrade) |
| Saybolt universal viscosity | 48 seconds at 98.9 degrees centigrade | 54 seconds at 37.8 degrees centigrade |
| Pour point | +10 degrees centigrade | Lower than −32 degrees centigrade |
| Burn point | None | None |

liquids are in marked contrast. Exposed to an oxidizing atmosphere under the most severe conditions, little if any chemical change can be observed. The color and original neutrality are essentially unchanged. No water, gas, or sludge is formed. The initially high resistance to water emulsification is retained with resultant high dielectric stability.

Figure 1 illustrates the marked difference in the dielectric stability of a typical transformer noninflammable synthetic dielectric liquid as compared to the usual mineral transformer oil. The materials were placed each in a clear glass, 5-gallon bottle, maintained at atmospheric temperature, and equipped with an inverted breathing tube open to the atmosphere in such a manner that the direct entrance of water (moisture or rain) was prevented, although free breathing produced as a result of atmospheric temperature changes was allowed. Clear glass bottles were used in order to promote any possible chemical change due to sunlight. Free breathing to the atmosphere was allowed in order that atmospheric moisture might slowly be accumulated in each liquid. Since chemical changes, if present, would include acid formation, liquid darkening, sludge formation, and water accumulation, the relative dielectric stability of the 2 liquids was expected to be demonstrated. As shown in figure 1, the nonoxidizing synthetic liquid gave practically no change in dielectric strength throughout the test exposure. The oxidizable mineral oil showed a slow drop in dielectric strength during the first 16 days of exposure, followed by a severe drop in dielectric strength between the sixteenth and the thirtieth day. At this time, the chemical changes in the oil were sufficiently advanced such that oil acid and sludge had accumulated in the liquid. In both the oil and the noninflammable liquid containers, water had accumulated, on the top of the synthetic liquid and at the bottom of the mineral oil. The test was discontinued after 182 days.

Organic hydrocarbon liquids, if exposed for long periods at high temperature to air and moisture, will oxidize and deteriorate. Under such conditions, the noninflammable synthetic liquids described in this paper show negligible change, either chemically or electrically. Typical results are illustrated in figure 2. The setup consisted of a glass vessel containing the synthetic liquid and connected to a reflux water condenser. Distilled water was added in an amount equal to about 10 per cent of the volume of the synthetic liquid which was heated sufficiently to maintain a slow refluxing of the water. The liquid temperature was approximately 100 degrees centigrade. Metallic aluminum was placed in the body of the liquid dielectric in order to detect any generation of corrosive chlorine formed from the long-time moisture contact in the presence of air. None was observed. The liquid showed no substantial increase in color or acidity. As shown in figure 2, the high dielectric strength of the liquid was maintained.

The superior dielectric strength characteristics of the noninflammable synthetic liquids, when tested with the usual oil-testing procedure, using a 0.1-inch liquid gap, is maintained with greater gap distances. Tests up to a gap distance of 2 inches are illustrated in the data of figure 3.

The dielectric strength of both the noninflammable synthetic liquid dielectric and mineral oil is a logarithmic function of the gap distance. The logarithmic relation, however, changes with increasing gap distance above approximately one inch. This change is illustrated in figure 4. Its technical significance is at present under investigation. For the larger gap distances above one

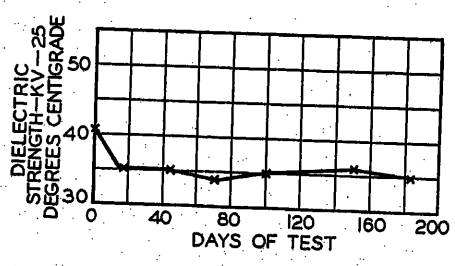

**Figure 2. The dielectric stability of noninflammable synthetic insulating liquids**

Setup: Liquid refluxed with water in presence of aluminum and air. Dielectric strength determined with rapidly applied voltage application using one-inch brass-disk electrodes spaced 1/10 inch apart

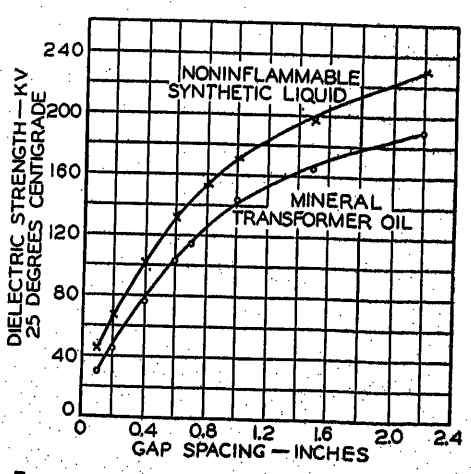

**Figure 3. The dielectric strength-gap distance relation for mineral transformer oil and a noninflammable synthetic insulating liquid of similar viscosity**

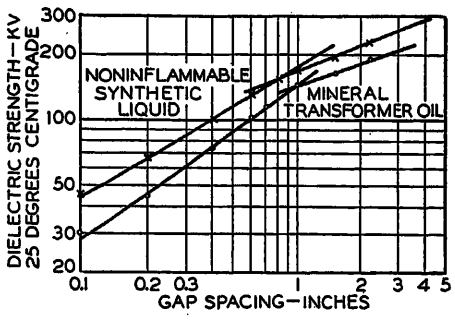

**Figure 4. Showng the logarithmic relation between dielectric strength and gap distance for mineral transformer oil and a noninflammable synthetic liquid of similar viscosity**

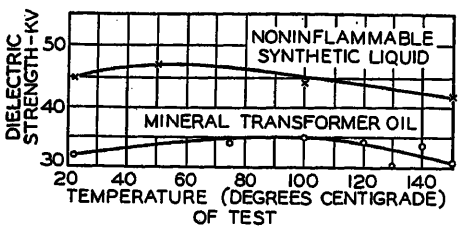

**Figure 5. The comparative dielectric strength of mineral transformer oil and noninflammable synthetic liquid of like viscosity as a function of the testing temperature**

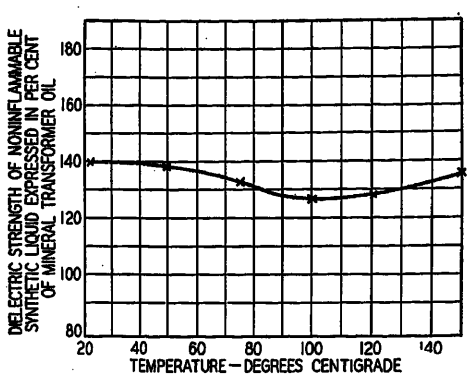

**Figure 6. The increased dielectric strength obtained with the noninflammable synthetic transformer insulating liquid expressed in terms of the dielectric strength of mineral transformer oil as a function of the testing temperature**

inch, the noninflammable synthetic dielectric liquid shows a dielectric strength about 20 per cent higher than that obtained with mineral transformer oil. For the smaller gap distances below one inch, the superiority in dielectric strength of the noninflammable synthetic liquid varies from approximately 20 per cent to as high as 50 per cent as the gap distance is continuously decreased.

Expressed logarithmically for the tests of this survey, the dielectric strength of oil and noninflammable synthetic liquids varies with the gap distance in accordance with equations 1, 2, and 3, in which $T$ indicates gap distance.

For mineral oil below one-inch gap distance:

$$Kv = AT^{0.70} \quad (1)$$

For noninflammable synthetic liquid dielectrics below one-inch gap distance:

$$Kv = AT^{0.59} \quad (2)$$

For both oil and noninflammable synthetic liquid dielectrics above one-inch gap distance:

$$Kv = AT^{0.37} \quad (3)$$

Figure 5 illustrates the effect of temperature change on the dielectric strength of a typical transformer noninflammable synthetic liquid dielectric and mineral transformer oil, each tested with rapidly applied voltage application between one-inch brass disk electrodes spaced $^1/_{10}$ inch apart. As already described in previous papers[6] the dielectric strength of mineral transformer oil increases with increase in temperature to 100 degrees centigrade. The noninflammable synthetic dielectric liquid shows a similar change in dielectric strength with increase in temperature, but reaches its maximum value at about 55 degrees centigrade, above which temperature its dielectric strength decreases in an approximately linear relation to the temperature increase. While at room temperature, the synthetic liquid is approximately 40 per cent higher in dielectric strength than mineral transformer oil, at 100 degrees centigrade the advantage has been reduced to 27 per cent. Above 100 degrees centigrade, the superiority of the noninflammable synthetic liquid again increases due to the more rapid drop in dielectric strength of mineral transformer oil as the temperature is further increased. The relationship is illustrated in figure 6.

It has already been suggested[6] that the change in the dielectric strength of insulating liquids with temperature reflects changes in the liquid-dissolved air content. It is to be observed that the changes in the dissolved air content of the noninflammable synthetic liquid dielectric discussed in these paragraphs predict the change in dielectric strength observed. The dissolved air content at normal atmospheric pressure and the corresponding dielectric strength at 25 degrees centigrade and 100 degrees centigrade for the noninflammable synthetic dielectric liquid under discussion are indicated in the following tabulation:

| | Dissolved Air Content | | Dielectric Strength | |
|---|---|---|---|---|
| | 25°C | 100°C | 25°C | 100°C |
| Mineral transformer oil | 10.0 | 11.3 | 32.0 | 35.0 |
| Noninflammable synthetic liquid | 6.3 | 6.0 | 45.5 | 44.5 |

## The Dielectric Strength of Treated Insulation

The ability of an insulating liquid to impart a high dielectric strength to cellulosic insulation is one measure of its usefulness. It is frequently considered that all insulating liquids possess equal ability to impart dielectric strength to solid insulation unless prevented by exceptional physical characteristics. Since most liquids heretofore investigated have been of petroleum origin, this generalization has been apparently well-founded. With the noninflammable synthetic liquid dielectrics of the type under discussion, however, 2 important changes have been introduced. The first is that the characteristic dielectric strength of the liquid has been raised by more than 20 per cent, depending upon the testing temperature and gap spacing. The second is that the dielectric constant has been materially increased. Over the range of temperature from 25 degrees centigrade to 100 degrees centigrade, the dielectric constant of the noninflammable synthetic

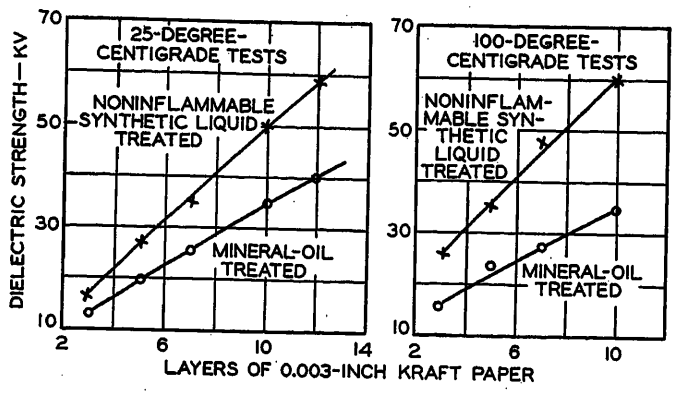

**Figure 7. The comparative dielectric strength of mineral oil and noninflammable synthetic-liquid-impregnated kraft paper**

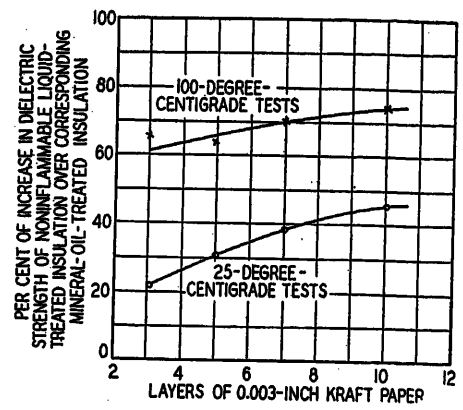

**Figure 8. The superiority of the noninflammable synthetic-liquid-impregnated 0.003-inch-kraft-paper dielectric expressed in terms of the corresponding mineral-oil-treated dielectric**

Testing temperature —25 degrees centigrade and 100 degrees centigrade, as indicated

Testing procedure—Minute test

Insulation thickness —0.004 inch (8 sheets of insulation)

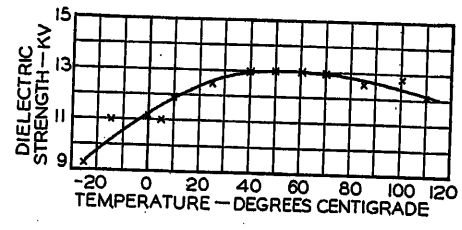

**Figure 9. The dielectric strength-temperature relation for 0.0005-inch-kraft-paper insulation impregnated with the transformer type of noninflammable synthetic insulating liquid**

liquid under discussion varies from 5 to 4, a value more closely approximating that of the cellulose material itself than does the dielectric constant of mineral oil or related hydrocarbon mixtures, the characteristic dielectric constant of which is approximately 2.2. Since liquid-impregnated cellulosic insulation in laminated structures, such as is normally used in commercial dielectrics, is essentially a series arrangement of liquid and solid, the advantage of an equalized dielectric constant as between the liquid and solid is immediately evident. Higher breakdown values for the noninflammable synthetic liquid impregnated cellulosic insulation are to be expected, not only because of the increased dielectric strength of the liquid itself as compared to mineral oil but also because of the more equal stress distribution resulting from the equalization of the dielectric constant of the liquid and the cellulosic base.

Figure 7 illustrates the dielectric strength of 0.003-inch kraft paper impregnated insulation, tested by the "minute test" voltage procedure, both at 25 degrees centigrade and at 100 degrees centigrade. The presence of the synthetic liquid increases the breakdown of the paper insulation as compared to the corresponding oil-treated value, the increase in breakdown increasing as the total thickness of the pad tested is increased. This is illustrated in figure 8.

Figure 9 illustrates the temperature effect on dielectric strength for noninflammable synthetic liquid-impregnated insulation, tested by the "minute test" procedure from −20 degrees centigrade to +100 degrees centigrade. The insulation in this case consists of 8 layers of 0.0005-inch kraft capacitor paper.

The advantageous dielectric strength characteristic of insulation impregnated with the noninflammable synthetic insulating liquid is undoubtedly related to thermal phenomena. Under conditions which prevent serious heat accumulation effects, the dielectric strength of mineral oil-treated insulation or untreated insulation is a logarithmic function of the thickness and approaches the first power function of the thickness factor. With test conditions which allow greater thermal effect, although the logarithmic relation is sustained, the dielectric strength increases at a decreased function of the insulation thickness.[7] The following relationships have been established for insulation tested in the form of flat pads:

Untreated kraft paper at 25 degrees centigrade, rapidly applied voltage

$$Kv = AT^{0.92 \text{ to } 1.0} \quad (4)$$

Untreated kraft paper at 25 degrees centigrade, minute test voltage

$$Kv = AT^{0.92 \text{ to } 1.0} \quad (5)$$

Mineral-oil-treated kraft paper at 25 degrees centigrade, rapidly applied voltage

$$Kv = AT^{0.90 \text{ to } 0.95} \quad (6)$$

Mineral-oil-treated kraft paper at 25 degrees centigrade, minute test voltage

$$Kv = AT^{0.75} \quad (7)$$

The dielectric strength data of figure 7 are also a logarithmic function of the insulation thickness. The "minute test" breakdown at 25 degrees centigrade for 0.003-inch mineral-oil-treated kraft paper agrees well with the previously established relation (equation 7), breakdown varying with thickness in accordance with equation 8:

$$Kv = AT^{0.75} \quad (8)$$

The previous publication,[7] however, did not demonstrate that when the temperature of the test is increased, the logarithmic relation correlating breakdown and insulation thickness changes, again reflecting the effect of heat accumulation. The data of figure 7 and figure 10 describing the dielectric strength-thickness relation for mineral-oil-treated kraft paper at 100 degrees centigrade indicate the following expression:

$$Kv = AT^{0.66} \quad (9)$$

In table II, rapidly applied test breakdown data are given for impregnated kraft paper tested at 25 degrees centigrade. Complete data covering a wide range of insulation thicknesses are not illustrated. Such studies, however, clearly substantiate the logarithmic relation between dielectric strength and insulation thickness whether the kraft paper be impregnated and tested under mineral oil or the synthetic noninflammable liquid. The formula established from these studies relating the dielectric strength under rapidly applied tests at 25 degrees centigrade for both types of impregnants is given in equation 10:

$$Kv = AT^{0.90 \text{ to } 0.95} \qquad (10)$$

The similarity in the dielectric strength-thickness relation for kraft paper insulation impregnated with mineral oil and the synthetic liquid when tested at 25 degrees centigrade with rapidly applied voltage procedure is to be expected since under these conditions heat effects are negligible. When, however, longer time voltage tests are used the kraft paper insulation impregnated with the noninflammable synthetic liquid dielectric shows a closer approach to a linear relation of thickness and dielectric strength than that established for mineral oil-treated insulation. This is illustrated in figure 10. While in this instance the dielectric strength at high temperature is a decreased logarithmic function of thickness, the effect of change in insulation thickness for the synthetic liquid treated insulation always more closely approximates a linear relation than that observed for the corresponding mineral-oil-treated dielectric. This is indicated in the following formulas set up for 0.003-inch kraft paper impregnated with the noninflammable synthetic liquid dielectric and tested in accordance with minute test voltage application procedure:

$$\text{At 25 degrees centigrade, } Kv = AT^{0.04} \qquad (11)$$

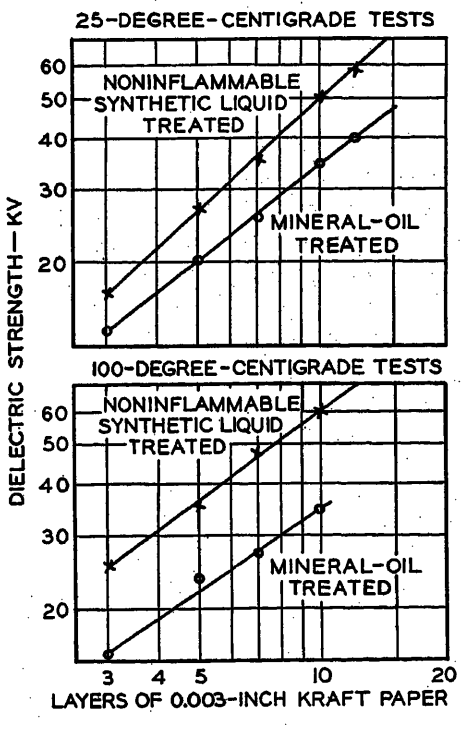

**Figure 10. Illustrating the logarithmic relation between dielectric strength and thickness for 0.003-inch-kraft-paper insulation impregnated with mineral transformer oil and synthetic noninflammable dielectric liquid of like viscosity**

Testing procedure—Minute test (data based on figure 7)

**Table II. The Comparative Rapidly Applied and Minute-Test Dielectric Strength of Impregnated Kraft Paper**

Test temperature—25 degrees centigrade
Voltage applied—60 cycles
Insulation—0.003-inch impregnated kraft paper
Test medium—Same as impregnating medium

| | Average Dielectric Strength | | |
|---|---|---|---|
| | Rapidly Applied Voltage, (Kv) | Minute Test Voltage, (Kv) | Per Cent Decrease Due to Extended Time |
| Oil impregnated—10 layers | 41.0 | 35.0 | 14.7 |
| Noninflammable synthetic-liquid-impregnated—10 layers | 55.5 | 50.0 | 9.7 |
| Oil impregnated—15 layers | 59.0 | 47.0 | 20.3 |
| Noninflammable synthetic-liquid-impregnated—15 layers | 80.0 | 72.0 | 10.0 |

$$\text{At 100 degrees centigrade, } Kv = AT^{0.71} \qquad (12)$$

The dielectric strength of mineral-oil-treated insulation decreases with the duration of voltage application. With the so-called "life test," in which the voltage application extends over weeks and months, this effect may be produced by voltage or by heat accumulation, both of which result in chemical deterioration in the dielectric assembly. Such effects are not susceptible to easy demonstration under laboratory conditions. Data available, however, indicate clearly that the marked chemical stability of the noninflammable synthetic dielectric liquids as compared to the susceptibility of the hydrocarbon oils to oxidation and other forms of chemical change is reflected in the greater electrical stability of the treated insulation.

Test temperature—25 degrees centigrade
Voltage application—Minute test procedure
Test form—Flat pads
Electrodes—Aluminum foil

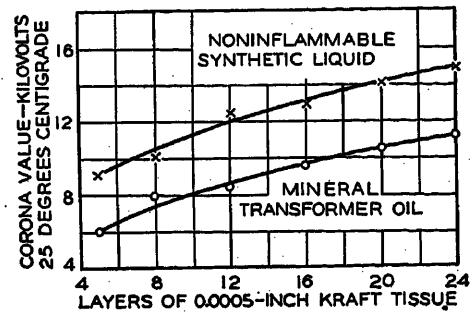

**Figure 11. The visual corona-formation point for mineral-transformer-oil-treated and synthetic-liquid-treated 0.0005-inch-kraft-paper dielectric**

Voltage application—Minute test procedure
Dielectric thickness—0.004 inch
Electrodes—Aluminum foil

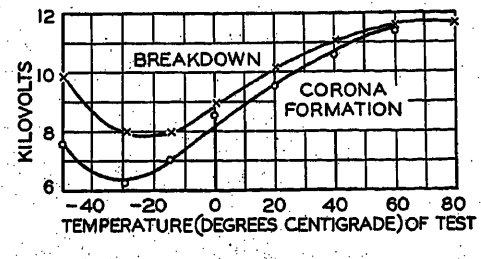

**Figure 12. Corona formation and breakdown of noninflammable synthetic-liquid-treated 0.0005-inch-kraft paper as a function of the testing temperature**

The dielectric superiority of the noninflammable synthetic-liquid-treated insulation is indicated even under conditions of test in which air and oxygen are carefully excluded in order to eliminate mineral-oil-oxidation effects. Thus in one typical group of tests, dielectric assemblies were prepared each consisting of aluminum electrodes separated by 3 sheets of 0.0004-inch kraft tissue. The electrodes were $2^7/_8$ inches wide and 94 feet long. The rolled assembly was vacuum dried, impregnated and tested in a gas-free hermetically-sealed container. The following results clearly indicate the superiority of the synthetic-liquid-treated insulation even when tested under the most favorable mineral oil conditions:

| Dielectric Treated With | Mineral Oil | Noninflammable Synthetic Liquid |
|---|---|---|
| Number assemblies tested | 40 | 40 |
| Voltage applied (60 cycles) | 880 | 880 |
| Volts per mil | 733 | 733 |
| Ambient testing temperature | 30 degrees centigrade | 30 degrees centigrade |
| First dielectric failure | 1 day | 17 days |
| Total dielectric failures in 10 days | 7 (17½ per cent) | 0 (0 per cent) |
| Total dielectric failures in 25 days | 12 (30 per cent) | 1 (2½ per cent) |
| Total dielectric failures in 50 days | 15 (37½ per cent) | 2 (5 per cent) |
| Total dielectric failures in 70 days | 16 (40 per cent) | 2 (5 per cent) |

Laboratory demonstration of the greater time-voltage stability of the noninflammable liquid as compared to the mineral-oil-treated dielectric is also illustrated by the usual time-voltage relation in which the voltage is continuously applied for periods from one second to 1 or 2 hours. Reference to data already presented will serve to indicate the comparison. In table II, the 10-second breakdown (called "rapidly applied test") is compared to the so-called "minute test" procedure, in which the voltage is slowly raised over a period of about 10 minutes. In general, the effect of lengthened time of voltage application is less on the noninflammable synthetic liquid-treated insulation. Under the conditions outlined, a decrease in breakdown value of 10 per cent appears to be characteristic of kraft paper insulation impregnated with the noninflammable synthetic liquid dielectric. This compares to a corresponding average decrease of 17 per cent characteristic of the same dielectric when mineral-oil impregnated.

## Visual Corona Formation in the Treated Dielectric

The dielectric failure of insulation is inevitably preceded by the formation of corona in the liquid layer. With mineral-oil-treated insulation, because of the difference in the dielectric constants of the oil and the cellulosic insulation, coupled with the breakdown characteristic of the oil itself, corona may appear at relatively low voltage stress. With 0.0005-inch kraft-paper tested by the "minute test" procedure, the corona formation point of the noninflammable synthetic liquid-treated dielectric, depending upon the thickness of insulation tested, is from 30 per cent to 50 per cent higher than the corresponding corona formation point in the mineral-oil-treated dielectric. Figure 11 illustrates the corona formation value for mineral-oil-treated 0.0005-inch kraft paper as compared to similar insulation impregnated with noninflammable synthetic liquid of similar viscosity. The corona formation point is described as the voltage at which visual discharge appears at the edges of the aluminum foil electrodes used in this test setup, all tests being carried out under the same medium used for the impregnation of the kraft paper. With temperature increase, the corona formation of the noninflammable synthetic liquid-treated dielectric increases. Figure 12 shows the corona formation value in its relation to the ultimate "minute test" breakdown as the temperature is changed from −50 degrees centigrade to +80 degrees centigrade. With temperatures higher than 60 degrees centigrade to 80 degrees centigrade, the corona-formation voltage increases to the extent that it blends with the breakdown voltage and is visually indistinguishable therefrom. As the temperature is decreased below room temperature, the breakdown and the corona formation voltage do not decrease indefinitely but reach a minimum value in the range of about −30 degrees centigrade. Both values increase with further decrease in temperature. Such changes invariably accompany a change in physical state, liquid to solid, and are normal behavior of mineral oils as well as other dielectric liquids.

## Summary

The development of synthetic noninflammable chlorinated liquids of the aromatic hydrocarbon type places in the hands of the engineer a chemically stable material of high dielectric strength and possessing a dielectric constant approximately equal in value to that of cellulose itself. This insures a more equitable stress distribution in the composite insulation assembly normally used in commercial practice. The result is an increase in dielectric breakdown and related phenomena. No fixed relation defining the superiority of the synthetic noninflammable liquid or liquid-treated insulation is possible, since variation in test conditions changes the relative dielectric values. In general, however, the data indicate an advantage in favor of the synthetic liquid and liquid-treated insulation equal to at least 20 per cent of the corresponding mineral-oil value.

# Application of Arresters and the Selection of Insulation Levels

By J. H. FOOTE, FELLOW AIEE  J. R. NORTH, MEMBER AIEE

FOR many years, the insulation strength of power transformers and other electrical equipment was determined chiefly by the performance in service. When failures occurred, the insulation was made heavier at the points of weakness, and gradually the number of weak points was reduced in the particular lines of equipment and ratings involved. When new lines or ratings were initiated, operating experience was frequently necessary to perfect the design. Little information was available regarding the insulation strength of equipment under impulse conditions, and there was practically no selected co-ordination between the equipment strength and the performance of surge protective equipment.

The principal cause of equipment failures has been lightning, and much attention has been given during the past few years to the study of lightning phenomena and the behavior of insulation material under lightning stress. At the same time, the study of protective equipment has made available a knowledge of its behavior under lightning surge conditions. Great strides have been made in this direction, so that it is now possible to select insulation levels with a degree of confidence as to subsequent performance, provided that proper correlation of these phenomena and behavior characteristics is effected.

This paper describes a method of selecting the required insulation levels of transformers and other power system equipment according to the performance of the protective equipment.

A brief review of some of the important phases of the problem will first be given in order that the method proposed for the selection of insulation levels may be readily understood.

The most important factors are:

(*a*) The magnitude and duration of the overvoltages to which the equipment may be subjected

(*b*) The volt-time insulation characteristics of the equipment

(*c*) The performance characteristics of available protective equipment

## Overvoltages

Transformers and other power system equipment may be subjected to overvoltages due to:

(*a*) Switching surges and abnormal power system conditions

(*b*) Lightning

Switching surges are usually of relatively long duration, but their magnitudes generally do not exceed 3.5 times normal voltage.[1] On many systems, they are less than 2 times normal voltage. Dynamic overvoltage due to hydroelectric generator runaway or other abnormal unloading conditions may reach values as high as 2 times normal. Apparatus designed in accordance with AIEE alternating voltage dielectric tests has proved to be entirely adequate for such overvoltages arising from system operation.

Lightning is considered to be the principal source of insulation failure because of the very high values of voltage and the steep wave fronts involved. Lightning voltages may be the result either of a direct stroke or a traveling wave, and the effect on insulation depends upon the magnitude, the duration, and the rate of rise and decay of the surge potential. It is apparently more economical and practical to take advantage of the protective equipment available and to utilize apparatus of an insulation strength properly co-ordinated with this protective equipment than to attempt to build apparatus in the present operating voltage ranges which will be able to withstand lightning surges without the use of some auxiliary protective device, either separate from or integral with the apparatus.

## Protective Equipment

The fundamental duty of a surge voltage protective device is to discharge any surge successfully and to limit the voltage to values well within the impulse strength of the equipment. In this discussion, the protective equipment will be assumed to include lightning arresters properly applied, supplemented by gaps on line terminals and by direct stroke shielding.

### Lightning Arresters

A lightning arrester is a device which has the property of reducing the voltage of surges applied to its terminals, is capable of interrupting follow current (if present), and restores itself to its original operating condition without causing a disturbance on the system. A lightning arrester, due to its rapid breakdown or gap flashover and the relatively low voltage across it during discharge provides both short time and long time protection to insulation except for some direct strokes.

Typical protective characteristics of modern lightning arresters, based on information as available and including impulse breakdown voltages and the voltage across the arrester during discharge of surge currents of various magnitudes, are presented in table I. Complete performance characteristics of line-type arresters are presented in the report of the AIEE lightning arrester subcommittee.[2]

A paper recommended for publication by the AIEE committees on electrical machinery, protective devices, and power transmission and distribution. Manuscript submitted March 24, 1937; released for publication April 12, 1937.

J. H. Foote is supervising engineer and J. R. North is general engineer with The Commonwealth and Southern Corporation, (N. Y.) Jackson, Mich.

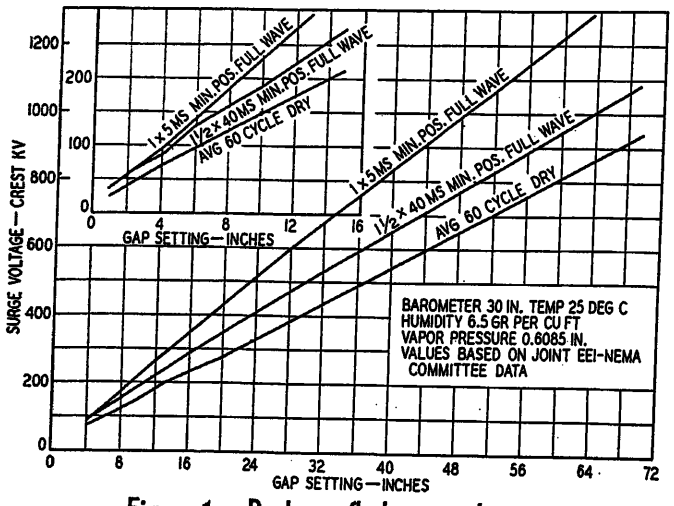

**Figure 1. Rod gap flashover voltages**

### Gaps

Various types of special gaps, such as the control gap, deion gap, and expulsion gap, have been developed. These have particular operating characteristics which govern their application and give varying degrees of protection.

The rod gap which has been extensively used in the past few years as a device for applying impulse tests on transformers and for co-ordination work in the laboratories, is defined as one consisting of $^1/_2$-inch square-cornered square-cut rods coaxially spaced and overhanging their supports at least one-half the gap spacing, and mounted on conventional insulators giving a height of 1.3 times the gap spacing plus 4 inches (±10 per cent tolerance) above the ground plane. Figure 1 shows the 1.5x40 microsecond, the 1x5 microsecond minimum flashover, and the 60-cycle characteristics of this rod gap. Figure 2 shows the approximate volt-time characteristics at various spacings. The protection afforded by rod gaps is discussed in another paper presented at this symposium.[3]

### Direct Stroke Protection

Shield wires or ground wires have proved themselves very effective for direct stroke protection when properly located and adequately grounded.[4] Shielding is of principal value in the protection of high-voltage lines and equipment against direct strokes and may be justified when the investment is proportionately high.

## Insulation Characteristics of Equipment

Various materials having markedly different insulation strength characteristics are used in electrical equipment. For example, a transformer consists of laminated insulation, solid insulation, oil, porcelain, and clearances in air. The volt-time characteristics of laminated and solid insulation are relatively flat, approaching the characteristics of a sphere gap. On the other hand, the volt-time characteristics of porcelain are approximately the same as rod gaps and show time lags at short time intervals. This is illustrated by figure 3. This disparity between the characteristics of the solid insulation and the bushing or rod gap necessitates that an insulation co-ordination study be made on a volt-time basis with full recognition of short time as well as long time phenomena.

Volt-time characteristics of apparatus insulation are not as yet generally available. It has, therefore, been necessary to study insulation levels largely in terms of voltages corresponding to some particular specified test wave condition. As a matter of convenience, the manufacturers have been expressing these insulation levels largely in terms of rod gaps, corresponding to some particular specified test wave condition. This has proved inadequate and basic insulation levels have recently been set up in terms of the minimum impulse flashover voltage on a $1^1/_2$x40 microsecond wave under standard conditions.[5] The latest authentic data available regarding the impulse strength of transformers is presented in reports by the AIEE transformer subcommittee.[6,7]

## Selection of Insulation Levels

An electrical station is composed of a number of component parts, i.e., transformers, circuit breakers, bus, etc., each including various types of insulation—air, oil, porcelain, and other materials. In order to render such a station as immune as practicable to transient voltage disturbances there must be a definite relationship between

| 169 | 570 | 500 | 620 | 700 |
| 242 | 820 | 720 | 890 | 1,000 |

**Thermal Ability**

The thermal ability is a function of the magnitude of the current and its duration. The line type arresters can withstand surge currents of 2,000–3,000 amperes crest and the station type arresters 10,000 amperes crest with surges of relatively long tails. These arresters can withstand a limited number of surges of higher current values provided they are of shorter duration.

the characteristics of the protective devices and the insulation strength of the equipment. Since overvoltages due to lightning are conceded to be the most serious source of trouble, then logically the characteristics of the surge protective equipment will form the criterion. *The insulation level of apparatus must be above the maximum surge voltage presumed to be allowed by the protective device on a volt-time basis over the range of time selected.*

The transformer is usually the most important piece of equipment in a station, both from the standpoint of cost and of service continuity. Furthermore, the major insulation in a transformer has practically a flat time-lag characteristic (figure 3) and this tends to make its protection from surges having high amplitudes and steep fronts a more serious problem than that of air, oil, or porcelain insulation. The protection of the transformer insulation has, therefore, been considered to be of prime importance in determining a proper insulation level.

Having available performance data on protective equipment and having evaluated the marginal factors, the determination of insulation levels is chiefly a matter of the selection and application of the protective equipment. The protective performance of modern lightning arresters has been selected as a suitable basis for the initial establishment of a series of protected insulation levels. Arresters generally have the following characteristics which are of value in this connection:

(*a*) A regular series of voltage ratings, including the distribution voltages, have been standardized.

(*b*) The performance characteristics as indicated in table I have been determined as typical, and it is assumed that the devices produced by the principal manufacturers have characteristics sufficiently similar to render them suitable for general application.

(*c*) The performance characteristics are such as to approximate the volt-time characteristics of transformer insulation.

(*d*) The performance characteristics are unaffected by weather and do not greatly change in general character with considerable change in voltage rating.

## Application of Lightning Arresters

The principal factors in the selection of the rating of a surge protective device, such as a lightning arrester or a gap, are:

(*a*) The maximum dynamic voltage which may occur between sound phase and ground under any fault conditions. The device must withstand this voltage without failure.

(*b*) The efficacy of the protective device in maintaining a low protected level and at the same time meeting satisfactorily the system operating requirements. The impulse volt-time characteristics must be below that of the equipment to be protected.

(*c*) The surge current which must be satisfactorily discharged. The thermal ability must be adequate for the currents expected.

The voltage rating of an arrester represents the maximum dynamic voltage which the arrester can withstand continuously and which it can interrupt after discharge. The arrester rating must, therefore, be greater than the maximum dynamic voltage which may occur between the arrester terminals during disturbances, allowing for the power system neutral being isolated, or grounded, as the case may be, and considering the actual maximum operating voltage. Allowance must also be made for the voltage recovery rate and any overvoltage conditions which may exist due to the overspeeding of hydroelectric generators, etc. The protection afforded by a lightning arrester is approximately proportional to its voltage rating and, therefore, it is important to use an arrester of as low a voltage rating as possible. Table II presents the general

**Table II. Typical Application of Lightning Arresters**

| System Voltage Classification | Approx. Range System Operating Voltage | Preferred Arrester Rating (Maximum Line-Ground Voltage, Kv) Neutral Not Effectively Grounded | Neutral Effectively Grounded |
|---|---|---|---|

application of arresters to systems in the various voltage classifications.

### Dynamic Voltage

The normal "full voltage" rated arrester is designed to operate on an ungrounded or isolated neutral system where the voltage existing between line and ground may at times equal the normal line-to-line voltage. The arrester rating is generally 5 per cent or more above the maximum operating voltage. Under favorable conditions where the system neutral is effectively grounded, better protection may be obtained by the use of an arrester having a reduced voltage rating, provided the upper limit of dynamic voltage is not exceeded under any operating condition. In the past "grounded neutral" arresters have had voltage ratings approximately 80 per cent of the "full rated" arresters. This gave a wide margin above the normal system line-to-neutral voltage to allow for fault voltages, etc.

For the purpose of determining the allowable arrester voltage rating, the maximum dynamic voltage which may occur during fault conditions between the sound phases and ground may be calculated by the method of symmetrical components. Under certain conditions, a 2-line-to-ground fault may be slightly more severe than a single line-to-ground fault.

For a single line-to-ground fault, Wagner and Evans[8] have shown that:

$$E_b = \frac{\sqrt{3}E_g}{2}\left[\frac{\sqrt{3}(Z_0 + R) + j(Z_0 + 2Z_2 + 3R)}{Z_0 + Z_1 + Z_2 + 3R}\right]$$

where

$E_b$ = voltage between sound phase and ground
$E_g$ = normal line to neutral voltage
$Z_1, Z_2, Z_0$ = sequence impedance to point of fault
$R$ = fault resistance

Arresters of reduced voltage rating should not be applied except where the neutral is "effectively grounded" and the following conditions are met:

(*a*) The neutral of that portion of the system must be grounded at all times and under all operating conditions.

(*b*) The ratio of zero-sequence impedance (including neutral impedance and fault resistance) to positive-sequence impedance or negative-sequence impedance ($Z_0/Z_1$ or $Z_0/Z_2$) must be equal to 2 or less under maximum fault conditions. Due consideration must be given to the circuit impedance as affected by sequential operation of circuit breakers at the ends of a line.

(*c*) The arrester voltage rating must be at least 10 per cent above the calculated maximum sound phase voltage to ground. In general it will be found that

if $Z_0/Z_1 = 2$ or less, an 80 per cent arrester may be used
if $Z_0/Z_1 = 1$ or less, a 70 per cent arrester may be used

These latter percentages should be applied to the *maximum* line-to-line operating voltage in determining the allowable arrester rating.

### Surge Currents

Considering traveling wave phenomena, it would be possible to calculate the magnitude of the surge discharge currents through the arrester for the various combinations of line and station insulation which may be encountered. These calculations, however, involve a number of indeterminate factors, including the surge impedance to ground, the magnitude and the wave shape of the surge, etc., and it is not generally considered feasible to make such calculations for each individual case. In the present discussion, the surge discharge current through station type arresters has been taken at 5,000 amperes crest and for line type arresters at 3,000 amperes crest. These values appear to be reasonably moderate in view of available field data[9,10] regarding lightning arrester surge currents. Furthermore, the voltage across the arrester during discharge does not increase in proportion to the surge current.

### Marginal Requirements

The typical performance of arresters, as given in table I, applies only to the arresters themselves, without any tolerances or margins. It must be realized, however, that with any protective device, an adequate margin must be provided above its performance characteristic to allow for manufacturing tolerances, different types of installations and to insure proper selectivity between the protective performance of the device and the apparatus insulation. The necessary margin is thus affected by a number of factors and should cover both long time im-

pulses and short waves of steep front and high crest.

The following tolerances and marginal items have been considered in this analysis with values as indicated:

(*a*) *Tolerances* in performance characteristics of arrester. Based upon manufacturer's information, these have been taken as:

Gap breakdown voltage = plus 5 per cent to 25 per cent

*IZ* drop across arrester during discharge of specified current = plus 5 kv + (5 per cent to 15 per cent)

(*b*) Effect of *distance and potential gradient* during surge conditions which may generally exist between the protective device and the apparatus on the basis of modern station layouts. The capacitance of station equipment will be effective in reducing the slope of the incoming surge wave. In the larger high-voltage stations this mitigates against the higher reflected surge voltages and complete double voltage reflections would not be expected unless the station capacity were very small and the station located at the terminal of a line.

The possibility of flashover occurring on the front of the wave, rather than on the tail of the wave as considered in the recent AIEE test procedure using waves of moderate crest, has been taken into account by considering steep wave fronts and both the short time and long time characteristics of insulation and protective devices. Considering the magnitudes of surge voltages and the reflection effects which may reasonably be expected, it appeared that a short time potential gradient of one kv per foot should be adequate allowance for distance, arrester connections, etc. Arresters to be effective should be located as close as possible to the apparatus being protected. In the case of 2,400-volt and 4,800-volt pole-mounted units, the distance between the arrester and the equipment has been taken as 4 circuit feet, with a gradual increase up to 150 circuit feet for the 240-kv class installed in stations.

(*c*) *Selectivity Margin.* It is necessary to provide an adequate margin, both with respect to time and voltage, to insure that the protective device shall function properly before insulation breakdown or damage may occur. There is apparently little definite information available pertaining to the margins which may be necessary. After reviewing past operating experience and correlating the performance of arresters in service with the information available regarding existing insulation levels, it has been concluded that a selectivity margin of some 30 kv to 40 kv (in addition to manufacturing tolerances and circuit gradient) is the minimum which may be used in the transmission-voltage classes.

## Protected Levels

In this analysis, arresters have been utilized on the basis of the voltage rating being approximately equal to the system line-to-line voltage, i.e., the use of a full rated arrester. The actual application of an arrester on a particular power system should ordinarily be on the basis of using one rated as low as permitted by the maximum dynamic voltage which might exist between sound phases and ground as previously described and the protection would be proportional to the voltage ratings shown.

Table III presents an analysis of the performance characteristics of station and line type arresters and includes the various marginal values which have been described. The terms "short" and "long" coupling have been used to designate the location of the arrester relative to the transformer being protected.

Figures 4 and 5 illustrate the arrester performance and station equipment insulation levels on a volt-time basis with a $1^1/_2 \times 40$ microsecond minimum positive wave. Figure 4 assumes a 23-kv system requiring a 25-kv arrester. This arrester will have a gap breakdown potential of 85–89 kv, and the breakdown will take place in approximately one-half microsecond. The voltage across the arrester when discharging 5,000 amperes will be 100–110 kv. With manufacturing tolerances and with the circuit gradient given in table III, there exists a net selective margin between the basic insulation level and the arrester performance of 27 kv to 40 kv. In figure 5 the performances of 60-kv and 73-kv arresters are compared with the volt-time characteristics of 69-kv equipment, basic level, and with the AIEE test rod gap of 20.6 inches. It will be noted that the net selective margins between the basic level and the arrester amount to 35 kv to 40 kv for the full rated 73-kv arrester and 80 kv to 92 kv for the 60-kv arrester.

Figure 6 shows the relation between the recently agreed upon basic insula-

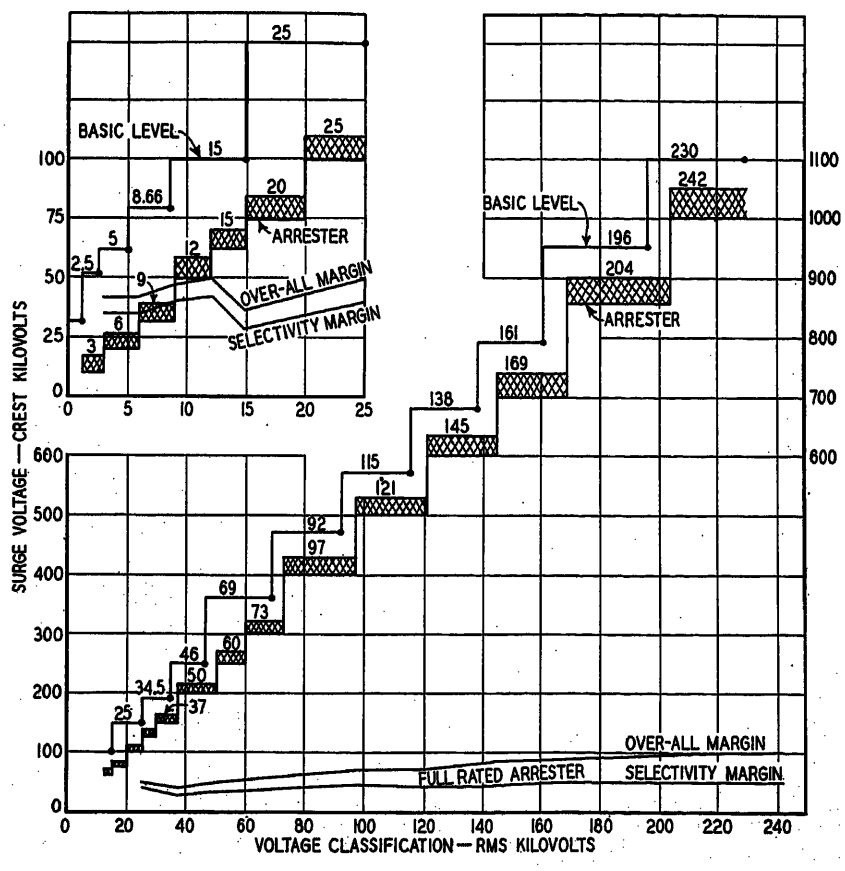

**Figure 6. Margin between arrester and basic insulation level**

Station-type arrester; current = 5,000 amperes

tion levels[5] and arrester performance when discharging 5,000 amperes surge current. The margin between the arrester performance and the long time insulation level of equipment will generally be greater than is indicated by this analysis because the surge currents will not be maintained at high values for long periods of time. Incoming surges which produce these heavy currents will generally have caused flashovers out on the line and will thus be chopped. The margin at short time intervals will also be somewhat greater than indicated because the insulation strength of apparatus is inherently higher than the basic level at short time intervals. These margins between the arrester performances and the basic levels generally range from 30 kv to 100 kv in the various voltage classifications, as shown in table III. In certain cases, such as in the 15-kv classification, the margins are relatively small. In cases where arresters do not have as favorable characteristics as have been considered herein, or where conditions are unusually severe, the margins will be still smaller or even nonexistent.

## Conclusions

Insulation co-ordination requires a study of the entire surge protective scheme and, among others, the following items should be considered.

(*a*) Lightning arresters of suitable characteristics connected metallicly and as closely as possible to the equipment to be protected.

(*b*) Protective gaps having suitable flashover voltage characteristics and located on the line side of oil circuit breakers connected to overhead lines. Gaps should not be mounted directly on transformer or breaker bushings.

(*c*) Ground wires properly installed on overhead lines and extending an adequate distance out from the station.

This study of the co-ordination of insulation indicated that insulation levels for various operating voltages could be assigned, depending upon the class of service, the performance of the surge protective equipment utilized, and the economics of the situation. This has been substantiated by years of operating experience with apparatus installed in stations wherein the insulation was designed in accordance with these principles.

Furthermore, it may be concluded that:

(*a*) Full rated lightning arresters which have suitable performance characteristics and which are properly located will provide protection for the basic insulation levels[5] listed in table III (except the 15-kv level) down to extremely short time intervals, except for some direct strokes or unusually severe conditions.

(*b*) Lightning arresters of less than full voltage rating can be utilized on systems having the neutral effectively grounded and will give a greater margin of protection than will full rated arresters. In such installations, apparatus having impulse insulation strength levels one step below the basic level will be protected if the arresters have suitable characteristics.

(*c*) The impulse insulation strengths of electrical apparatus in the various voltage classifications should be equal to or greater than the corresponding basic insulation levels.

(*d*) The alternating voltage dielectric tests for particular conditions should be in conformity with the operating requirements and the insulation level selected. Under particularly favorable operating conditions, it seems reasonable that the alternating voltage dielectric tests may be reduced below present levels.

## Synopsis

A quantitative investigation of the surge protective requirements of distribution systems and the power frequency voltage requirements of protectors for these systems, has been made which leads to the conclusions that:

1. The surge current discharge capacity of protectors should be 100,000 amperes to prevent damage from lightning. In general, 50,000 amperes capacity will give satisfactory results.

2. The surge voltage breakdown characteristics should be similar in shape and lower in value than the transformer insulation.

3. Field experience, as well as laboratory tests, have proved that a high degree of protection is obtained with a ratio of protective device initial discharge voltage to normal frequency voltage of 9 to 1 in voltage classes up to 13.8 kv, compared to the present conventional arrester rates up to 3.5 to 1.

4. Testing of protective devices under conditions more nearly representative of their service requirements should be considered.

## I. Function and Operation of Surge Protective Apparatus

THE MENACE of lightning to electrical power lines and apparatus is the high surge voltage produced on them which breaks down insulation and renders the line unfit for service. Following such breakdowns, current will flow from the line to ground in order to discharge the energy induced in the line by the lightning stroke. This current may reach extremely high values, and since an arc is usually associated with its conduction to ground, burning and physical destruction may be severe. Finally, large magnetic forces are caused which may damage lines and associated apparatus.

The highly concentrated energy discharge associated with the lightning stroke may be transmitted to the power line in either of 2 ways. First, the lightning discharge may terminate directly on a line conductor, in which case the entire current of the lightning stroke must pass through the line and associated apparatus to ground. This is called a direct stroke. Second, if lightning strikes in the vicinity of a power line, the electrostatic field is raised to such a high value that a considerable overvoltage is induced in it.[1,8] Such surges are called induced surges or indirect strokes. As a result of either direct or indirect strokes, the surge on the line will travel along it in both directions with very high velocity. The wave shape of the surge will change, however, and the traveling wave will be attenuated, so that in the course of even a short distance, the overvoltage will be considerably smaller and the length of the wave considerably greater than at the point where the surge originated.

Protective apparatus connected to power lines for the purposes of minimizing lightning damage must provide a short and direct path to ground in the event of a surge, so that the induced voltage on the line will be held to a value lower than its insulation level. The simplest means of protecting the line and connected apparatus is to suddenly ground it in the event of a lightning discharge. A spark gap is the simplest form of device which can be used for this purpose. The gap will be broken down by the overvoltage introduced on the line and will very quickly pass sufficient current so that the voltage on the insulation will be limited to a small value.

This simple expedient is not ideal, however, since the voltage at which the gap will be broken down increases with increasing rates of voltage rise, and consequently the protection provided is not uniformly good. The volt-time characteristics of such a device are shown in figure 2, curve *D*. Furthermore, the breakdown voltage of a simple gap is erratic and not subject to close control.

A simple gap also has the very great disadvantage that after the lightning phenomenon is over, the line is left grounded. This means that short-circuit current will flow in most cases, and circuit breakers must be opened in order to clear the gap. Consequently, there is a line outage. It becomes then a required characteristic of the lightning protective device that it automatically opens the established circuit between line and ground after complete discharge of the lightning stroke energy.

To accomplish this result it is essential that the simple gap be fundamentally modified. There are 2 known ways of making lightning protectors self-clearing. One principle is to connect a valve element in series with a gap from line to ground. This valve element is so constructed that the impedance drop across it is substantially constant and somewhat greater than the crest of the normal line to ground power voltage. The lightning surge voltage will then be limited to this impedance drop and the "valve" together with its series gap will pass current sufficiently freely to so limit the voltage. After the surge energy of the lightning stroke is discharged only a small current will pass through the valve due to the high impedance which is reached as the surge current decreases. Since it has been impossible to construct a theoretically perfect valve element, the series gap has been introduced to serve the dual purpose of "interrupting" the small residual current which remains after the surge discharge and of isolating the valve from power voltage under normal conditions.

A paper recommended for publication by the AIEE committee on protective devices. Manuscript submitted March 30, 1937; released for publication April 30, 1937.

J. K. HODNETTE is transformer engineer with Westinghouse Electric & Manufacturing Company at Sharon, Pa.; L. R. LUDWIG is division manager for the same company at East Pittsburgh, Pa.

1. For all numbered references see list at end of paper.

The second principle is to enclose the gap in walls of fiber which evolve gas under the action of an arc so that high interrupting capacity is obtained. In this device under some conditions a larger power follow current may flow just after the surge discharge, but it is interrupted at the first current zero. A series resistor is used to limit the magnitude of this power current.

Qualitatively, the common requirements of a satisfactory lightning protective device are:

1. The device must be capable of passing without damage any lightning current to which it is subjected.

2. Its voltage breakdown characteristics should be as nearly linear with time as possible, and under all conditions lower than the apparatus which it is desired to protect.

3. Its impedance drop when passing such currents should be well below the insulation breakdown level of the apparatus to be protected.

4. After passing surge currents, the device must be capable of cutting off any flow of power current even with full power frequency voltage across it.

5. In order to prevent undue operation, the power frequency voltage required to "breakdown" the protective device should be substantially above the normally impressed voltage.

These requirements will be expressed quantitatively in the following sections.

## II. Surge Current Requirements of Protective Devices

For a number of years, engineers have been collecting quantitative data on the nature of lightning strokes—their magnitude, duration, polarity, probability of occurrence, etc., Measurements on transmission lines, distribution lines, and general field measurements have yielded valuable information on this subject. Direct and indirect measurements have been made. The latter have as their basis some physical effects such as mechanical forces, fusion effects, magnetic effects, etc., which are related to or calibrated by laboratory measurements. Indirect measurements have yielded much data on the magnitude and polarity of surge currents. More direct measurements are required to ascertain the shape and duration of surge currents and the nature of repetitive strokes.

The data available indicate the following:[1]

1. The most severe strokes from the standpoint of rate of voltage rise and magnitude of surge current are uni-directional single strokes negative in polarity.

2. Approximately 95 per cent of lightning strokes measured on transmission lines are negative in polarity.

3. Approximately 20 per cent of lightning strokes measured are repetitive.

4. The number of individual discharges in a repetitive stroke ranges from 2 to 10, or more, with the average number 3 to 4.

5. The total time duration of repetitive strokes is from a few hundred microseconds to one or more seconds with the impulses spaced about 0.03 seconds or more.

6. The rate of voltage rise of direct strokes is probably 1,000 to 3,000 kv per microsecond.

7. Measurements indicate a probable maximum surge current of about 200,000 amperes in rare cases.

8. The duration of individual surges varies up to 50 to 100 microseconds maximum with the average probably not over 25 microseconds.

Some of the data available are summarized in figure 1 for comparison. These data represent different methods of measurement. Curve *A* is determined from the fusion effect of lightning currents on metal electrodes of deion gaps and represents data on 4,000 transformer years.[2] From this curve, it appears that from 1/2 to 1 per cent of transformers in suburban and rural areas are subjected to surge currents of 10,000 amperes or higher, and approximately 1/4 per cent are subjected to surge currents of 50,000 amperes or higher.

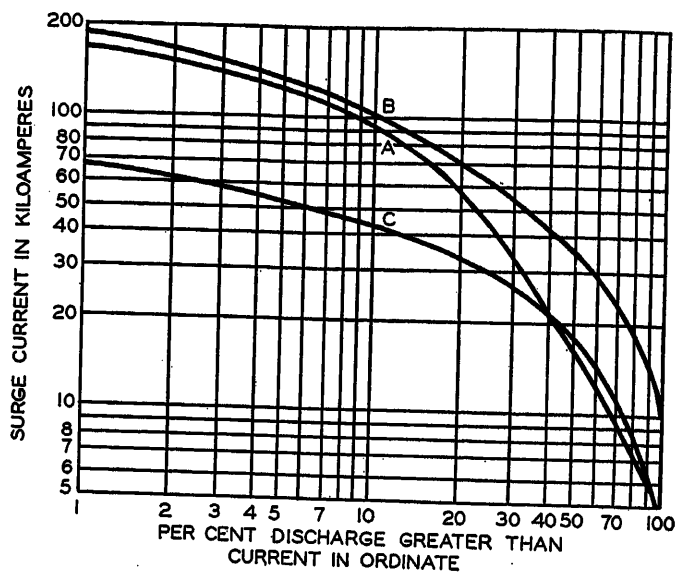

**Figure 1. Magnitude of lightning currents recorded by different methods of measurement**

*A*—Lightning currents at suburban or rural distribution transformers as indicated by fusion effects. 4,000 transformer years[2]

*B*—Lightning currents computed in tower legs on surge-crest ammeter. 911 tower years[3]

*C*—Lightning currents in towers above 5,000 amperes—surge-crest ammeter. 911 tower years[3]

Curve *B* of the same figure, shows the surge current in transmission towers above 5,000 amperes. These measurements represent 911 station years and 235 records in excess of 5,000 amperes were obtained. They indicate 19 per cent per year in excess of 10,000 amperes and 1 1/2 per cent per year in excess of 50,000 amperes.

Curve *C* is the computed currents in tower legs.[3] They are based on 911 tower years and 113 measurements, all of which are in excess of 10,000 amperes or a probability of 12 1/2 per cent per year at the particular location. The probability of currents of 50,000 amperes and higher as indicated by this curve, is 3.7 per cent.

Measurements by another method were made by H. W. Collins.[4] Out of approximately 500 measurements, in excess of one per cent were above 10,000 amperes with the maximum measured 20,000 amperes.

Additional valuable data on distribution lines has been contributed by McEachron and Halperin[5] on the probability of surge currents in shielded urban areas and by McEachron and McMorris[6] on more exposed lines. These data indicate that the probability of surge currents in excess of 10,000 to 20,000 amperes in shielded urban areas is very remote indeed. In rural areas, however, 1 per cent of the surges were found to exceed 15,000 amperes.

A summary of the data indicates that at least 1 per cent of the surge discharges will exceed 10,000 amperes and an appreciable fraction of 1 per cent will reach 50,000 amperes. An efficient and satisfactory protective device should be capable of handling surge currents of this order of magnitude.[7]

In analyzing data of this nature, it is necessary to take into account the natural difficulties of measurements. Due to the numerous points of low insulation level of distribution lines, diversion of current through multiple paths takes place easily, so that measurement at any one point may not be indicative of the maximum currents to be expected. From the physical concept of the problem, it would be expected that the maximum currents would be of the same order as those obtained on high voltage transmission lines, particularly in exposed circuits.

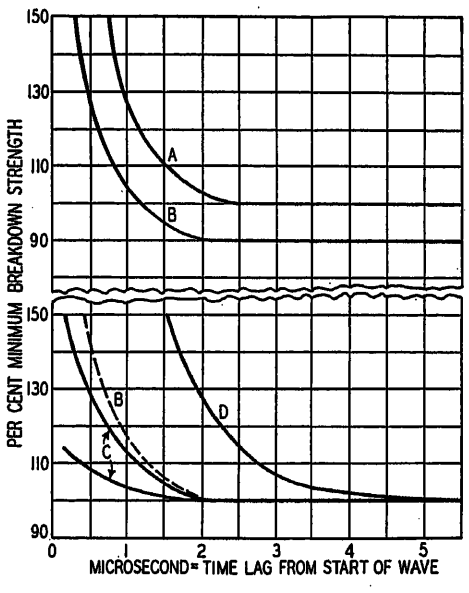

**Figure 2. Comparison of impulse characteristics of distribution transformer insulation and protective devices**

*A*—Breakdown characteristics of distribution transformer insulation

*B*—Probable voltage and time curve at which deterioration begins

*C*—Flashover characteristics of deion gaps and arrester gaps compared with *A* and *B*

*D*—Approximate shape of bushing and rod-gap flashover curves (13.8 kv class) compared with *A* and *B*

The probability of surge current of a given magnitude occurring at any particular location on a distribution system decreases rapidly with increasing current. Some potential exists by induction at practically all locations every time there is a lightning discharge in the vicinity. The nearer the discharge to the line, the higher the potential on the line will be. Due to the reduced insulation level at transformer locations and other points along the line, induced currents exceeding 2,000 amperes would not be expected. With the advancement in the art of surge protection, transformer insulation and protective devices, currents of this amplitude are of no serious consequence. The serious problem of protecting distribution systems, as well as high-voltage transmission systems, is to deal with direct and near direct strokes. In distribution systems, this problem is complicated by the fact that most distribution lines are carried on wooden poles having a high insulation value to earth. Also, the resistance of the earth at the poles may be quite high. This combination of factors makes it possible for surge currents of high magnitude to travel long distances along distribution lines and be diverted to earth through the low resistance path of the transformer secondary services. This means that lightning does not have to strike very near transformer locations for them to be subjected to high surge current. With the rapid extension of distribution systems into exposed rural areas, adequate surge protection afforded by protective devices capable of handling severe lightning stroke currents is paramount.

The time duration of surge discharges through lightning protectors has not been as completely measured as the current magnitudes. Available data indicate, however, that a lightning stroke of 50,000 amperes will generally have a time duration of 25 microseconds at least. Consequently, time values of this order of magnitude should be considered in judging the surge current handling ability of protective devices.

The fact that many lightning strokes are repetitive argues that if the surge current capacity of a lightning protector is to be defined in terms of a single stroke, some allowance must be made for the cumulative dissipation of energy associated with multiple strokes. Consequently, there is additional reason for placing the minimum acceptable surge current capacity at a high value.

## III. Voltage Protective Requirements

Adequate protection of distribution transformers and other equipment on distribution lines necessitates that the protective device limit the voltage that can exist on the insulation of the equipment to a value that will not damage any part of it. In considering the voltages existing on a distribution system, one has to take into account the high density of transformer locations and other points of reduced insulation. It is impossible, therefore, for voltages of very high magnitudes to be propagated on distribution lines as traveling waves. In general, impulses of this character are harmlessly drained off to ground by protective devices even under unfavorable grounding conditions. Impulses of a more dangerous or damaging character appear as a rapidly rising voltage suddenly reduced by a flashover of the line or a discharging of the protective device, followed by a building up of current through the circuit so formed to earth. This current produces a voltage drop by virtue of the impedance

of the protective device itself and of the circuit in which it is connected. It is imperative that the impedance of this circuit be sufficiently low so that the voltage impressed on the apparatus under the most severe conditions of surge discharge will not damage the insulation of the apparatus. Both the impedance of the protective device and the surge impedance of leads and connections must be small and, consequently, it is necessary that the connections be made as short as possible. To illustrate this fact, it is possible to build up voltages in excess of 10,000 volts per linear foot in straight conductors in the laboratory. All beneficial effects of the protective device can be nullified by long connections.

Distribution transformers are the major apparatus connected to distribution systems. The quality and characteristics of the insulation is an important factor in the successful operation of the distribution system. The normal frequency voltage strength must be sufficiently high to prevent damage from normal overvoltages, arcing grounds, etc., and to prevent corona and radio interference. This is insured by acceptance tests specified by the AIEE. Knowledge of the insulation strength of transformers to impulse voltages is necessary to intelligently co-ordinate and successfully apply protective devices.

A careful study of the impulse characteristics of distribution transformer insulation has been made. Due to the many factors influencing the ultimate impulse strength of transformer insulation, quantitative data can best be analyzed on the basis of average results or guaranteed values.

There exists a fairly definite ratio of the impulse strength of well balanced transformer insulation to its normal frequency strength. This ratio has been expressed numerically as 2.2, based on the 60-cycle crest value of the insulation breakdown strength. Applying this factor to the acceptance test voltages gives an indication of the minimum impulse strength built into transformers by the manufacturer. These values for low voltage distribution transformers are given in table I. In this class of apparatus the manufacturer maintains a much higher margin of safety to minimize mechanical defects and to insure reliable service than in higher voltage apparatus. While this margin cannot be definitely utilized, it nevertheless aids in preventing damage from lightning.

The volt-time characteristics of the insulation and protective devices is shown in figure 2. Curve *A* shows the characteristics of transformer insulation for a $1^1/_2 \times 40$ microsecond wave. The minimum or full-wave impulse strength is represented as 100 per cent and as a function of time in microseconds from the start of the voltage wave. The shape of this curve was determined by the average of a large number of tests to failure of actual distribution transformers.

Curve *B* of figure 2 shows the probable limits of voltage and time below which deterioration of the insulation is not expected to occur. The shape and values of this curve are established by applying repeated impulses of a given voltage and time duration to a transformer and noting whether or not deterioration begins. In applying this curve to a particular transformer, it is necessary to take into account the natural variation or spread in impulse strength of transformers of the same voltage class and design. It is applicable to the figures in table I, directly without encroaching upon the manufacturer's margin of safety.

On the same figure, curve *C*, showing the volt-time characteristics of deion gaps and lightning arresters, is given. Note that these curves are lower and flatter than curve *B*. Also, the approximate shape of the voltage-time flashover of bushings and standard rod gaps for 6,900-13,800 volt class transformers is shown as curve *D*. While these 2 curves are not exactly of the same shape,

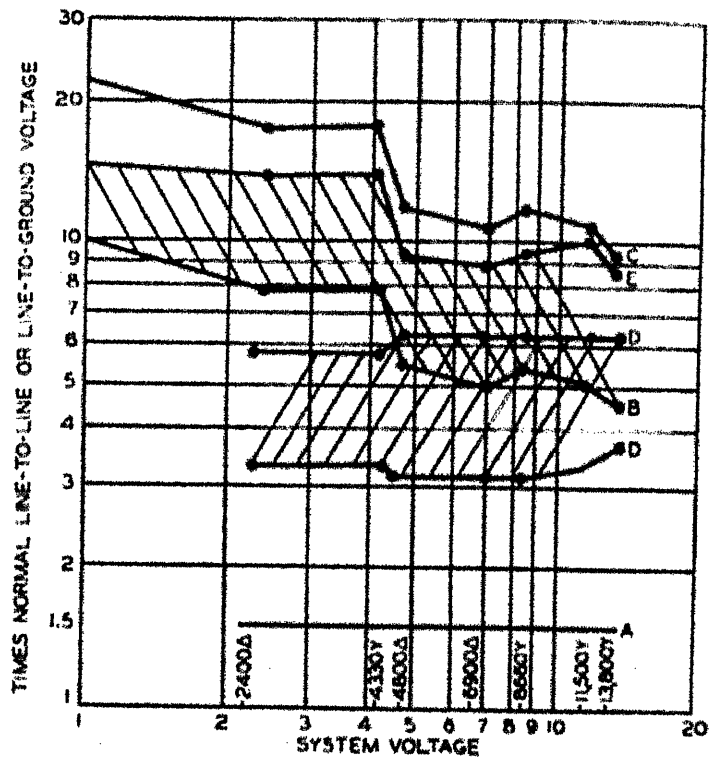

**Figure 3. Comparison between protective devices and transformer test levels**

*A* Minimum 60-cycle voltage requirements of protectors
*B* One minute dielectric acceptance test
*C* Minimum impulse strength based on *B*
*D* Valve type lightning arrester breakdown voltage level
*E* Deion gap arrester breakdown voltage level

they have the same general characteristics. Note that the bushing and rod gap curves are higher than the curve of probable insulation deterioration, as well as the insulation breakdown strength. For lower voltage classes, both the rod gap and bushing flashover characteristics are flatter due to their more uniform dielectric fields. It is necessary, however, to resort to considerably shorter gaps than the recommended co-ordinating gaps before the flashover curves are similar in shape to the insulation breakdown curve.

These curves illustrate the desirability of a surge

protective device having voltage discharge characteristics similar in shape to the insulation characteristics of the transformer, and also the fact that standard bushings and rod gaps do not have this.

The history of past development shows that protective-device engineers have constantly endeavored to design and produce apparatus which would be more reliable and which would have a lower ratio between discharge voltage and normal frequency line voltage. These 2 requirements have not been entirely compatible and have been accentuated by code requirements. With the advancement in the knowledge of the characteristics of natural lightning and with it the theory of surge protection, the codes have been modified to remove these restrictions. Transformer engineers have kept pace by obtaining knowledge of transformer insulation characteristics and limitations. The protective-device engineer should have a free hand to design apparatus suitable for the service required of it and unhampered by past traditions. This means simply proper co-ordination of transformer insulation levels and protective-device discharge voltage. As indicated by table I, it is satisfactory to design distribution surge protective equipment for much higher discharge voltages than would have been considered practical several years ago.

## IV. Normal Frequency Requirements of Lightning Protectors

The desire to reduce the surge level of lightning protectors to a low value results in designing these devices so that their normal voltage cutoff is reasonably close to the applied power voltage. If this procedure is carried too far, the protector itself is endangered and it becomes a hazard to the power system. Consequently, at times there have been failures of these devices which were not associated with the discharge of lightning energy. It is, therefore, necessary to examine the power voltage conditions of the circuit to which the lightning protectors are to be applied, in order properly to design and use this type of equipment.

Generally, protectors are applied to 3-phase power systems. These systems may be operated with the neutral solidly grounded or free from ground. In either case, the normal line to ground voltage will be the line-to-line voltage divided by 1.73. In the event of a fault from one line to ground, however, the performance of the 2 classes of systems is quite different. The solidly grounded neutral system will, under theoretically ideal conditions, prevent the line-to-ground voltage during fault conditions, from rising at all. Actually this voltage will increase to a value of approximately 120 per cent normal line to ground voltage in average cases. If the neutral is not grounded, the full line-to-line voltage will appear from line to ground in the event of a ground fault on one conductor. Consequently, it is essential that the protective device be capable of interrupting the flow of power current after surge discharge with a voltage applied which will be at least 120 per cent of the normal line to ground voltage if the neutral is grounded, and which will be at least 1.73 times line to ground voltage if the neutral is ungrounded.

Grounded neutral systems are subject to considerable variation depending on the magnitude of the ground impedance. While the average overvoltage from line to ground in the event of a fault may be only 120 per cent, lightning protectors must operate satisfactorily on systems of high ground impedance. Furthermore, protectors may be located at a considerable distance from the point of actual grounding and a line to ground fault near the protector location effectively increases the ground impedance so far as voltage across the protector is concerned. It is very difficult to determine the maximum per cent of line-to-line voltage which the protector should withstand, but experience indicates that the value should be 80 per cent for solidly grounded neutral systems. In other words, the line-to-ground voltage will rarely exceed 140 per cent of its normal value.

Systems in the distribution voltage class are generally supplied with power through step-down transformers from higher voltage systems. In case lightning strikes the high-voltage system, surges of considerable magnitude may cause a flashover to ground and power current may flow through ground for several cycles. If the neutral points of the 2 systems are connected together to a common ground of comparatively high resistance, this flow of power current in the high-voltage system may introduce considerable overvoltage of power frequency in the low-voltage system. Direct flashover from the high to the low-voltage system during the surge is also a possible cause of high dynamic voltages on the low-voltage system. Obviously, the greater the difference between the normal voltage of 2 connected systems, the greater is the possibility of excessive power-frequency voltages introduced into the low-voltage network as a result of fault conditions. Consequently, it is good practice to build lightning protective devices at the lower voltages with a greater factor of safety or difference between maximum permissible line-to-ground voltage and normal line-to-ground voltage, than is the case with lightning protectors of the high-voltage class.

Generally low-voltage lightning protectors are applied with less care than high-voltage devices. Often it is not possible to employ a theoretically ideal rating because low manufacturing costs preclude the availability of a wide range of voltage classes. These facts again introduce the requirement that the voltage tolerance of distribution lightning protectors should be comparatively great.

Another factor which at times influences the required voltage cutoff characteristics of lightning protectors, is the presence of harmonics in the supply voltage, particularly during fault conditions. Normally the applied voltage is sufficiently sinusoidal so that the crest value bears the normal relation to the meter readings. During faults, however, saturation of transformer iron may introduce harmonic voltages. The nature of the main power source must also be considered, since waterwheel generators without damper windings are subject to producing high harmonic overvoltages during line-to-line short circuits. It is furthermore possible that in certain

cases various lines and connected apparatus will be resonant to these harmonics, and cases have been experienced where very high harmonic overvoltages were present during fault conditions from line to ground.

Surges resulting from switch operations on the lines may at times prove hazardous to lightning protector devices. Switching surges differ from lightning surges principally in 2 respects. First, the magnitude of overvoltage is much lower in the case of switching surges and major insulation is not endangered. Second, the duration of the switching surge may be much longer than the lightning surge, however, and the energy which must be dissipated in a protective device may be greater for the switching surge than for the lightning surge. Consequently, the lightning protector must be built sturdily enough so that it will handle any currents passing through it as the result of normal switching operations.

As lightning protectors are generally constructed, a certain minimum voltage must be impressed across them before they begin to pass appreciable current. In other words, these devices exhibit definite breakdown characteristics. Generally, the breakdown voltage of protectors is considerably higher than their cutoff voltage. This is fundamental in the design of these devices, because the isolating means is generally a gap of some form and it is impossible to design a gap so that it will interrupt current up to the voltage necessary to cause a breakdown. Furthermore, it is very desirable to set the breakdown voltage of the devices considerably above normally applied voltages, and in many cases higher than the normal switching surges. In this way unnecessary operations of the protective device are prevented.

In the distribution voltage class it has been general practice to have the breakdown voltage at least 1.5 times the maximum permissible voltage or cutoff value of the device. This figure is low for the best obtainable performance. The breakdown voltage at normal power frequency may easily be 2 to several times the cutoff voltage without impairing the surge protective characteristics, and if the designs are made in this way much greater safety of the protective device itself is obtained.

## V. Voltage Levels of Protective Devices

The 2 preceding sections define the upper limits of discharge voltage of protective devices, and the lower limits of power frequency cutoff and breakdown voltage. In figure 3 the minimum insulation impulse strength has been plotted (curve *C*) for the different distribution voltage classes. The basic data for this curve are taken from table I. Also the minimum acceptable power frequency breakdown voltage has been plotted in figure 3 (curve *A*). The difference between these 2 curves is a broad band into which the characteristics of the protective device must be fitted. Since the 60-cycle and surge discharge voltage of protective devices is different, or in other words since their impulse ratio is greater than unity, 2 curves must also be plotted for the protective device. These 2 curves again form a and which is much narrower than the band of required performance. The difference represents the total margin of safety of the protective device over service requirements. This total margin can be divided by design between margin over 60-cycle minimum requirements and margin under surge requirements. On account of the relatively great total margin, there is considerable choice in the design of the lightning protector.

**Table I. Comparison of Guaranteed Normal Frequency and Impulse Strength of Distribution Transformers Based on AIEE Standards and Recommendations**

| | | Expected Minimum Impulse Strength Based on | | | |
|---|---|---|---|---|---|
| | Dielectric | Dielectric | Test Gap | | Bushing |
| Voltage Class (RMS Kv) | Test (RMS Kv) | Test (Crest Kv)* | Inches | (Crest Kv)* | Flashover† (Crest) |
| 1.0 | 10 | 31 | 0.8 | 32 | 37 |
| 2.4– 4.3 | 19 | 59 | 2.2 | 59 | 68 |
| 4.8– 8.7 | 26 | 81 | 3.3 | 81 | 87 |

* Minimum flashover or full wave for 1½x40-microsecond positive waves.
† Maximum voltage applied in making impulse tests which flashes over bushing or equivalent gap. See recommendations of transformer subcommittee on impulse testing.

In figure 3 curves are also plotted showing the minimum 60-cycle and maximum surge characteristics of valve arresters (curve *D*). Arresters have been widely applied to protect insulation of varying and unknown surge strength, and consequently, their characteristics have been designed to be comparatively low. Deion protectors, on the other hand, have generally been designed as an integral part of distribution transformers of known insulation strength. Furthermore, the transformers are tested on 60 cycles with the deion protector connected, and it is consequently necessary to maintain the 60-cycle breakdown of the protector higher than the test voltage applied to the transformer (curve *B*). For these reasons, the deion protectors have surge characteristics considerably higher (curve *E*) than those of valve arresters. Field service records prove conclusively that both devices provide adequate protection to the transformers.

# Application of Spill Gaps and Selection of Insulation Levels

By H. L. MELVIN
FELLOW AIEE

R. E. PIERCE
MEMBER AIEE

## Synopsis

This paper presents, from the viewpoint of the engineer who plans and operates electric power systems, the application logic or theory and the performance results with various forms of spill gaps, for the protection of circuits and equipment from lightning, and the selection of insulation levels co-ordinated with this type of protection.

The performance results are largely confined to transmission voltages, although the same general principles and logic apply over the entire transmission and distribution operating voltage range.

## Background

AS A BACKGROUND of scientific research, service observation, and engineering experimentation the industry has available the results to date of study in 4 fields, concerned with protection of circuits, equipment, and service against lightning:

1. Field research of natural lightning, also laboratory research, having to do with the nature and occurrence of lightning[1,2,3]

2. The volt-time characteristics of insulators and insulating materials under impulse and normal frequency voltages[4,5]

3. The performance characteristics of gaps and lightning arresters in commercial use[4,6]

4. Analyses of observed operating performance of electric transmission and distribution systems with particular reference to protection from lightning[2,7]

In none of the above 4 fields of investigation and experience can it yet be said that the results or knowledge are so complete that unqualified conclusions can be drawn with respect to each of the pertinent factors in the problem. Nevertheless, enough has been learned that it has been possible to formulate tentative insulation and protection policies and to secure from actual experience a reasonably conclusive check as to their soundness.

## General Aspects of Lightning Protection

As in most transmission and distribution problems the best solution to the protection problem is judged in terms of both performance and cost.

Protection from lightning has 2 primary aspects:

1. Protection of equipment against damage
2. Protection of service against interruptions

Each of these is capable of separate evaluation, and obviously is dependent on such factors as density of load, type of load, and degree of exposure to lightning.

The methods available for accomplishing protection may be broadly divided into the 2 groups of shielding and drainage.

### Shielding

Shielding of circuits and equipment is accomplished either by underground construction, or by the so-called "lightning proof" type of construction. To be effective, the shielding must be capable of withstanding all direct strokes of lightning, except possibly the most severe, without breakover or conduction of the lightning current to the power conductors.

Shielding within the limitations of the specific installation, protects service and equipment. Unfortunately it is economically feasible only in the case of the higher transmission voltages, and on circuits of major importance.

In the lower transmission and distribution range of voltages, overhead circuits are not generally shielded. There are also many situations with the higher transmission voltages, where lightning storms are infrequent or where lines serve large areas having small load densities, where the added investment for shielding disqualifies it from the standpoint of economy.

### Drainage

Drainage is accomplished by providing for relief and limitation of lightning voltages through flashover at preferred locations. This includes the use of:

1. Plain gaps with which no attempt is made to interrupt or seal off power follow current

2. Fused gaps in which the series fuse interrupts the power follow current. These have limitations in application with respect to interrupting ability

3. Lightning arresters which do not permit power follow current. Their effectiveness is limited to their surge current discharge capacities

4. Arc-interrupting gaps, in which the series tube interrupts the power follow current. These tubes have limitations with respect to minimum and maximum interrupting ability, and their application as at present commercially available is confined largely to line insulation protection

## Application of Spill Gaps

The logic underlying the application of spill gaps of any type is:

1. A spill gap provides a definite voltage discharge level with very high capacity for discharging lightning stroke current. The setting may be in terms of inches of air or in terms of voltage and time. The cost of the installation is the very minimum

A paper recommended for publication by the AIEE committees on protective devices, power transmission and distribution, and electrical machinery. Manuscript submitted March 29, 1937; released for publication April 27, 1937.

H. L. MELVIN and R. E. PIERCE are electrical engineers for Ebasco Services, Incorporated, New York, N. Y.

The authors acknowledge the use of much information available both from previously published papers and from reports covering the performance of transmission and distribution systems of operating companies with which the authors are associated. These operating data have made possible the most valuable part of this paper.

1. For all numbered references see list at end of paper.

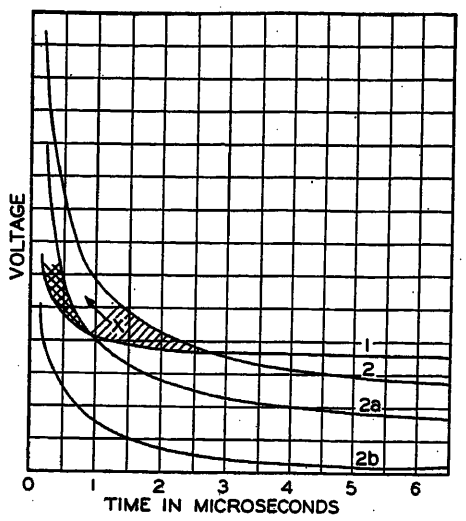

**Figure 1**

2. Except for solid or oil insulated equipment, practically all line and substation insulation can be expressed approximately in terms of equivalent inches of air

3. Co-ordinated with line insulators, bushings, switch and bus insulators, spill gaps provide dependable relief from dangerous surge voltages, at preferred locations for flashover, establishing definite levels in terms of inches of air or in terms of voltage and time

The usual application of the different types of spill gaps is:

1. Spill gaps of the extinguishing types, that is, arc-interrupting gaps or fused gaps, installed along a transmission or distribution circuit, are used for 2 purposes:

*a.* To provide a definite margin under the line insulation so that flashovers along the line will occur at the gaps, with interruption of power-follow current, to prevent line outages

*b.* To limit the voltage impressed on the circuit and transmitted to installed equipment

2. Plain spill gaps are installed at substations:

*a.* At the line entrances, with margins under all other insulation levels within the substation

*b.* Within the substation, on the bus or at equipment, with discharge levels somewhat higher than those established at the line entrances, as final or back-up protection against bus flashover or equipment failure

3. Fused spill gaps are installed at substations either at line entrances or on the bus or at equipment in a manner similar to and supplementing plain spill gaps to protect against service interruptions. Their use depends upon the expected frequency of lightning flashovers and the type and importance of the load served.

## Selection of Insulation Levels

### Basic Insulation Levels

During early discussions on insulation co-ordination it was common practice to think of insulation levels in terms of the amount of porcelain insulation or in inches of air (rod gap), in which case a level would not be a level in terms of voltage but would vary with the volt-time breakdown curve of the rod gap or insulators.

More recently, the accepted measure of a basic insulation level is in terms of volts, and is therefore more truly a level, being a constant value of voltage, regardless of the time to breakdown, except that the time is limited to a range in microseconds usually associated with impulse voltages.

Nevertheless, insulation as used, does not have a fixed voltage breakdown strength, and the volt-time breakdown curve of each unit of insulation or piece of apparatus is its own insulation level.

A "basic" insulation level serves no other purpose than as one of a series of standardized voltage bench-marks to which the insulation levels of line and station insulators, bushings, transformers, protective devices, and other equipment may be referred in the process of selecting a proper or desired level of insulation for a particular installation and working out co-ordination.

The minimum practicable basic insulation level that may be established for a given installation must be high enough so that insulation flashovers or failures will not occur from normal frequency overvoltages or from surge voltages originating within the system, such as switching surges.

The adoption of these minimum insulation levels on a system would result in minimum initial investment in line and station equipment insulation. This practice may not be practicable in specific situations, as for example a basic insulation level above the minimum often will be advisable in order to provide (1) equipment levels that will directly withstand or are capable of being protected against incoming traveling lightning voltages, or (2) equipment levels that can be adequately protected against severe nearby direct strokes of lightning.

### Insulation Levels for Equipment

The selection of the insulation levels for the bus and equipment, such as transformers, co-ordinated with a given basic insulation level, must take into account:

1. The relative volt-time characteristics of the other equipment including the protective device

2. The economic margin of protection, taking into consideration the expected severity and frequency of occurrence of lightning surge voltages

3. Margins to provide for variations in insulation strength due to manufacturing tolerances and from deterioration

Insulation research has demonstrated quite definitely that the breakdown of insulating materials under impulse voltages is a function of voltage and time. For fibrous insulations of most equipment the volt-time breakdown curve has the general shape of curve 1, figure 1. The curve is relatively flat except at the very short time intervals.

The impulse flashover characteristics of gaps are found to have the general shape of curves 2, 2*a*, and 2*b*. As compared to the curve for solid insulation, the gap curves are not as flat, voltage values rising sooner as the short time region is approached.

Assuming gaps and insulation as illustrated, gap 2*b* would prevent flashovers of gap 2*a*, and gap 2*a* would protect gap 2. Gap 2 would protect the insulation represented by curve 1 only against impulse voltages rising to flashover of the gap in a time longer than that point on the time scale where the 2 curves cross. Impulse voltages rising to crest or to flashover of the gap in region *X* would damage the insulation represented by curve 1. A greater time range and margin of protection would be secured to the insulation by gap 2*a*, and over the entire time range il-

lustrated, with margin, by gap 2*b*. These are equivalent to providing protection against more severe lightning impulse voltages.

In spite of the large amount of work which has been done investigating actual strokes of lightning, insufficient knowledge and data are available concerning the voltage magnitudes and rate of rise at the point of stroke incidence and the relative probable frequency of occurrence of direct strokes of the greatest severity. For the present at least, reliance must be placed upon the record of operating experience to tell when a satisfactory degree of protection has been achieved.

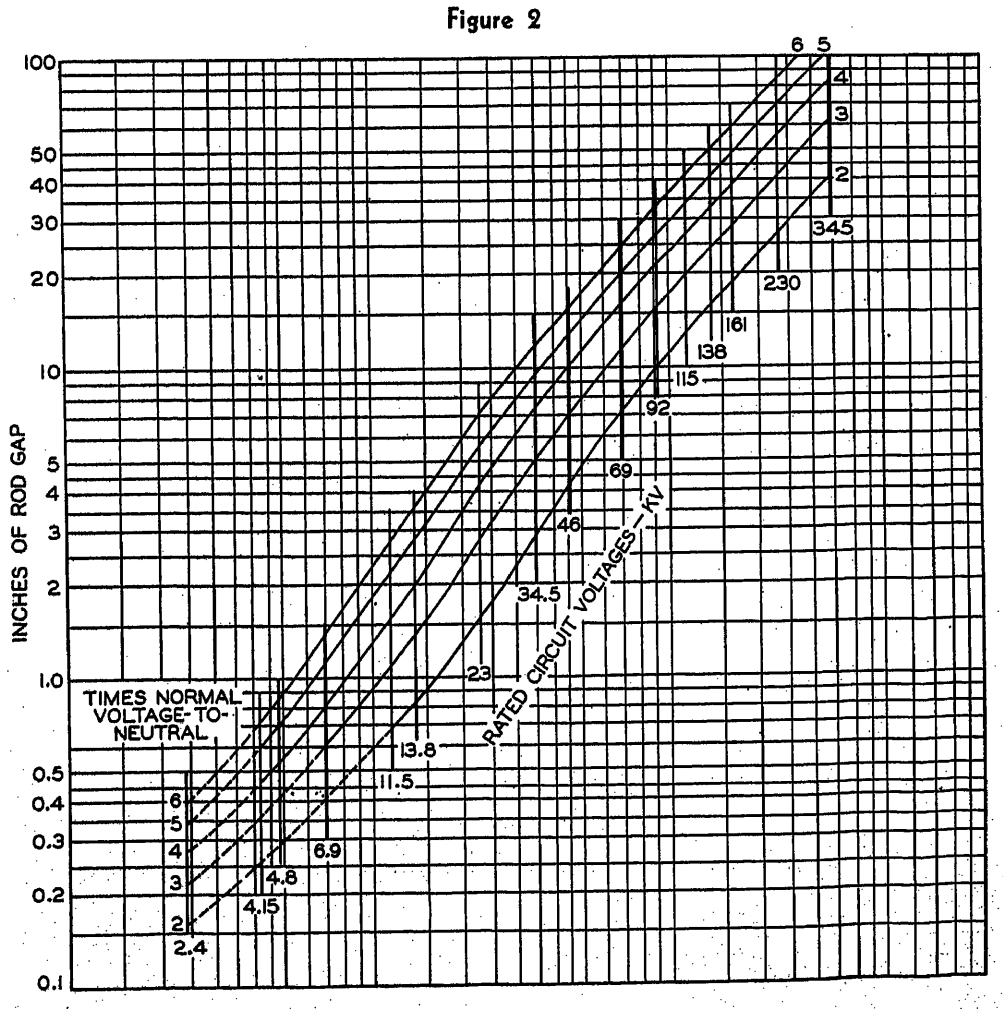
## Operating Experience With Spill Gaps

For discussing gap settings generally, without necessarily always referring to the associated system operating voltage, figure 2 has been prepared as a convenient reference chart, wherein the commonly accepted 60-cycle flashover values of rod gaps are plotted in terms of the number of times normal phase to neutral voltage, for the range of rated circuit voltages.

### Minimum Permissible Settings

Perhaps the most outstanding result secured from the observation of operating experience with gaps over the past several years is that, even in areas frequented by severe lightning storms, much lower spill-gap settings can be used than were originally considered possible.

For transmission voltages on grounded neutral systems, it generally has been found that gap settings corresponding to approximately 2 times normal (phase - to - neutral voltage) are the lowest possible. That is, gap settings of these magnitudes may be used without an undue number of flashovers, if any, due to switching surges. However, the more generally applied minimum gap settings in the transmission voltage range correspond to approximately 3 times normal voltage to neutral.



In the distribution voltage range, the minimum gap settings are relatively higher, as they are fixed, not so much by switching surges and overvoltages, as by mechanical and other considerations such as interference from birds, also higher settings are permissible due to the relatively greater prevailing insulation strengths of equipment.

Probably the extreme lower limit of permissible gap settings is typified by operating experience at a substation in Louisiana on the extensive 110-kv grounded-neutral system in the lower Mississippi Valley. This substation is at the end of a 110-mile section of single circuit H-frame line, having very high impulse insulation strength. Following a number of transformer failures, during which time the gap settings were reduced by steps from 31 inches to 18 inches, staged switching tests were made to determine the minimum permissible gap setting. In these tests the gap settings were reduced by steps to 10 inches. With the 10-inch setting during one setup on the system, these gaps flashed over twice during 15 switching operations, although on another system setup 65 switching operations did not cause flashover. The gap settings were increased to 11 inches and did not flash over during 45 switching operations under the same setup which caused flashover with the 10-inch setting.

These tests were made early in 1935 and the gaps have subsequently remained in actual service with the 11-inch setting during 2 lightning seasons. The gaps are of the repeater fused type, mounted directly at the transformer terminals. The setting of 11 inches is equivalent to approximately 1.7 times normal phase-to-neutral voltage.

At another substation on this same 110-kv system, where 11-inch repeater fused gaps were installed in 1936, further tests have definitely indicated that the switching surge caused by the opening of an oil circuit breaker on a

Figure 2

stub line can cause an 11-inch gap to flash over.

Early in 1936, at the first substation, 2 additional sets of repeating fused gaps were installed, with the 11-inch setting. Retaining the original set at the transformers, one new set was installed on the first structure of the incoming 110-kv line, and the other set on a line structure about 2 miles from the substation. During the year 1936, the total number of fused gap operations, on all 3 phases, at the 3 locations, were as follows:

| | Number of Operations of Repeater Fused Gaps |
|---|---|
| At the transformers | 28 |
| At the first line structure | 21 |
| At structure 2 miles away | 20 |

A definite correlation was not determined between fuse-gap operations at the 3 locations or between operations of individual fuse gaps and oil-circuit-breaker openings. There probably were a number of simultaneous operations of gaps. The evidence indicates that if any of the gap flashovers were occasioned by switching surges, they were successfully cleared by operation of the series fuses. During the year the line tripped out a total of 28 times due to lightning flashovers.

### Effect of Gap Settings on Number of Flashovers

Along shielded overhead circuits, the values of voltage induced on the circuit conductors through coupling effects, vary with the severity of the strokes of lightning to the line. The maximum voltage that can appear on the circuit at the point of stroke is limited to the line insulation level.

Along exposed circuits, there is probably less variation in the magnitude of the lightning voltages appearing on the circuits as it seems reasonable to assume that any direct stroke and most side flashes and branch streamers would cause line flashover, regardless of the amount of line insulation. The voltage therefore is determined by and limited to the line insulation flashover level.

In any case the impressed surge voltage at the point of stroke, travels toward the line terminals and appears at substations, after being subjected to the effects of attenuation and reflection, with magnitudes very seldom any greater and usually much less than at the origin.

Experience with both shielded and nonshielded lines in different parts of the country, all exposed to frequent and severe lightning, indicates that with gap settings at substations equivalent to or greater than 3.5 times normal phase-to-neutral voltage, there are relatively few gap operations compared with the number of line tripouts or line flashovers from lightning. There are an increasing number of gap flashovers, as lower and lower settings are used.

The following paragraphs cite typical experience with gap settings ranging from 3.5 down to 1.7 times normal, for transmission voltages. While only limited data are included, experience on these and other situations covers a period of 6 to 10 years.

As an example of experience with gap settings averaging 3.5 times normal for transmission voltages, and somewhat higher for distribution, the following number of stations were protected during 1935 and 1936 by spill gaps in central and eastern Texas. The performance record of these spill gaps during this period is summarized in table I.

| | Number of Substations Protected | |
|---|---|---|
| | 1935 | 1936 |
| 22 kv and above | 50 | 55 |
| 12.5 kv and below | 44 | 65 |
| On both high and low voltages | 20 | 25 |
| Total number of stations protected on either high or low voltage by spill gaps | 74 | 95 |

In Florida, on a 66-kv system, with line-terminal gaps set at 11 inches (approximately 3.0 times normal), and with line-insulation levels equivalent to 14 inches to 45 inches, of air, experience indicates that gap flashovers at the substations occur with about 4 per cent to 16 per cent of the lightning flashovers on the lines. The lower and higher percentage values are associated with lines of low and high insulation levels, respectively.

At a generating station bus in Arkansas, on the same Mississippi Valley 110-kv system previously mentioned 3 14-inch spill gaps per phase with series fuses (approximately 2.2 times normal) were installed in July 1934. In

† Line not put into service until after close of 1935 lightning season; 65 gap operations occurred on dead line
Note: Each of the four lines are single-circuit H-frame wood construction.

each of the years 1934 and 1935 there were 3 operations of the gaps, and in 1936 there were 4 occasions of gap flashover totaling 8 individual gap operations. All operations were associated with lightning and none caused service interruptions, except for one case in 1935 in which the fuse tube exploded.

At another substation in Arkansas similarly equipped in 1935 with 14-inch fused gaps on the bus, there were in 1936 3 occasions of gap flashover totaling 5 individual gap operations, without interruption to service.

At one of the 110-kv substations in Louisiana previously mentioned, the operating experience throughout the year 1935, with one 3-phase set of 11-inch repeater fused gaps (1.7 times normal) at the transformers, included a number of difficulties due to tube failures, also inadequate mechanical design of the fuse holder mechanism, which were not remedied until November 1935. In spite of, or including these difficulties, analysis of the record for the 1935 season shows at least 20 and perhaps 25 occasions of gaps operating, with a total of 37 blown fuses. During the same period the 110-mile connecting line having very high impulse insulation tripped out due to lightning 33 times. There were at least 8 occasions of gap operations totaling 10 blown fuses without line tripout, and there were at least 12 line tripouts without operation of these gaps.

Although at present this substation is connected to only one line, so that every line tripout causes a service interruption, the foregoing operating data indicate the possibility that had the gaps not been fused there would have been about a 30 per cent increase in the interruptions to service.

On extensive transmission and distribution systems in the Pacific Northwest, where lightning is not prevalent, a large number of plain spill gaps have been installed with settings approximating 2.5 to 3.5 times normal. There are practically no gap operations.

### Protection to Line Insulation

The experience with arc-interrupting gaps along transmission lines has shown that in most cases protection to line insulation and against service interruptions is secured. The first applications of this type of protection, made in Arkansas, continue to give fairly good performance. On the Pine Bluff-Dixie line (110-kv, H-frame, single circuit), approximately 46 miles in length, with arc-interrupting gaps at approximately $^1/_2$-mile intervals, the records show an average of 14.6 tripouts per 100 miles per year from lightning during the 4 years after the installation of these gaps, whereas during the 3 years prior there were approximately 38.0 tripouts per 100 miles per year from lightning. If the 2 periods can be considered otherwise comparable, there was a reduction of 60 per cent in the number of outages caused by lightning.

Another line in Arkansas, from Pine Bluff to Carpenter, (also 110-kv, H-frame, single circuit), 59 miles in length, was constructed with arc-interrupting gaps installed on every structure. This line operating in the same territory as the one mentioned above, shows an average number of outages caused by lightning over a 4 year period of 5.5 per 100 miles per year. Detailed descriptions of these installations were reported by Messrs. McEachron, Gross, and Melvin in 1933.[8]

On 4 sections of 66-kv transmission line in Pennsylvania during the 2 years 1935–1936 the results secured from the use of arc-interrupting gaps are set forth in table II. It will be noted in the case of the 2 lines partially equipped, that only partial protection is being obtained, and that all cases of damage occurred on structures which were not protected by gaps.

Plain gaps of various types for porcelain protection on transmission lines are effective, as is well known.

### Protection to Bus Insulators and Bushings

Analysis of the operating experience records shows that spill gaps properly set and connected, effectively protect bus insulators and bushings.

Out of the many thousands of installations, there have been only a few instances of failure to protect bushings, some of which probably were deteriorated internally.

For example, at one substation on a 132-kv system in Texas, 28-inch gaps (3.5 times normal) are installed on the first and second line structures adjacent to the substation. During 1936, the top half of one oil-circuit-breaker bushing was shattered by lightning, and another similar bushing flashed over. On the 66-kv system in this same territory, one oil-circuit-breaker bushing punctured below the flange, which should have been protected by a 12-inch spill gap (3.0 times normal).

In other locations there have been a few instances where insufficient physical separation existed between a gap and the porcelain it was supposed to protect, with resulting thermal damage to the porcelain.

### Protection to Transformers

With respect to the protection of transformer insulation by spill gaps, a few examples of experience data should be of interest.

On the 66-kv and 110-kv systems in the Carolinas, a rather general application was made during the period from 1929 to 1931 of fused gaps and plain gaps at the line terminals. These gap settings ranged from 12 to 15 inches on the 66-kv lines (3.0 to 3.8 times normal), and from 25 to 30 inches on the 110-kv lines (3.8 to 4.5 times normal). The average number of transformer units that failed from lightning during the 5 years up to and including 1928 was approximately 8 per year. For the 5-year period beginning with 1932 the average number of transformer units that have failed has been approximately 3 per year.

An alarming number of transformer failures occurred from lightning at scattered locations throughout the extensive Mississippi Valley 110-kv system during the years immediately following the major expansion and construction program, with as many as 10 failures in a single year. Where protective levels were previously in the range of from 24 inches to 31 inches they were in almost all cases reduced to 20 inches or less, and the record since of transformer failures from lightning is 1934, 4; 1935, none; and 1936, one.

At a 110-kv station in Arkansas, previously mentioned, there were 2 failures of transformers from lightning prior to 1934. This station is at the end of a 59-mile 110-kv line, equipped with arc interrupting gaps at each structure. In 1934, rod gaps set at 18 inches were installed directly shunting the high-voltage bushings of the 110-kv transformers. Within 3 months after installation there were 7 flashovers of these gaps and one more failure of a transformer. Following this experience there were installed on the switchyard bus, 9 14-inch fused gaps—3 per phase. This installation is located at the switchyard approximately 800 feet from the transformers. The lines connecting the transformers to the switchyard are equipped with overhead ground wires. A second transmission line extending from this switchyard has been in service during 1936. During the last 2 years there have been no further flashovers of the 18-inch gaps at the transformers or transformer failures and there were 14 operations of the 14-inch fused gaps on the bus.

Mention has already been made of a series of transformer failures occurring within several years at a 110-kv substation in Louisiana, with gap settings of from 31 inches to 18 inches. All failures occurred in the low-voltage windings from lightning voltages transmitted through the transformer. The low-voltage windings are connected to cable circuits and not exposed to lightning.

The first failure occurred in March 1931 with ring-ring gaps set at $27^1/_2$ inches adjacent to the substation, on the line structure. In June 1932 rod gaps set at $26^1/_2$ inches were installed on the substation structure and 31-inch rod gaps immediately adjacent to the transformers. Also 4-inch gaps were installed on the low-voltage (13.8-kv) bus. In April 1933 another transformer failed from lightning and on August 15, 1933 2 more transformers failed. The substation and transformer gaps were then changed to a 20-inch setting. At the same time overhead ground wires were installed over the substation and on the 110-kv line for a distance of about 3 miles out. Another failure occurred in April of 1934 and still another in August 1934. Thus there were a total of 6 failures in 4 years.

Fused gaps arranged with 3 sets of fuses for repeater closing were installed in November 1934 with the gap set at 14 inches. Between then and June 1935, 5 operations of these gaps occurred, each one successfully clearing the circuit without interruption to service or transformer failure. A series of switching tests (previously described) were then made and the gap setting arbitrarily reduced to the minimum practicable setting of 11 inches. At the same time the gap settings on the 13.8-kv bus were reduced from 4 inches to 2 inches and lightning arresters were installed on the 13.8-kv phase and tap leads. In the 2 year period since these last changes, there have been no failures of transformers.

## Conclusions

1. Spill gaps are effective as a means of establishing and co-ordinating insulation levels on lines and stations, and affording dependable protection to equipment and insulation, against failure from lightning.

2. The minimum permissible spill-gap settings, for transmission voltages, without adverse effects on service, are less than those previously considered possible.

*a.* The lower limit generally applicable is the equivalent of approximately 3.0 times the normal phase-to-neutral voltage, in terms of 60-cycle flashover

*b.* When extremely low protective levels are necessary or desirable, and preferably where fused gaps may be applied, the minimum permissible limit may be approximately 2.0 times normal

*c.* The foregoing spill-gap settings are associated with experience to date with existing lines and equipment. No conclusion or recommendation is attempted with regard to the application of desirable levels to specific situations or for guiding future practice

3. In the range of distribution voltages, spill-gap settings in terms of times normal voltage to neutral are relatively higher. Experience indicates that this practice is logical and practically necessary because of interference with closely set gaps, also the practice is permissible with the relatively greater prevailing insulation strengths of equipment.

# System Recovery Voltage Determination by Analytical and A-C Calculating Board Methods

By R. D. EVANS
MEMBER AIEE

A. C. MONTEITH
ASSOCIATE AIEE

THE PERFORMANCE of current interrupting devices on systems is dependent not only on the characteristics of the device itself but also on the characteristics of the system. The voltage rating of the system and the connections at the time of fault have considerable influence on the recovery voltage and in turn on the application of the interrupting device. For example, the last oil circuit breaker to open must be capable of interrupting current under extreme system recovery conditions, while a deion protector tube always has at least the line section on which it is applied, connected at the time of clearing. This means that in considering broadly the current interruption problem it is necessary to have a knowledge of voltage recovery characteristics for a large number of system conditions. Tests can be made for particular system conditions, but this is expensive and it is difficult to obtain data for all possible combinations of faults and system connections. A general analysis taking into account all the factors makes calculations practically impossible, and on account of the complexity, the human factor cannot be overlooked.

It is the purpose of this paper to present a method of obtaining system recovery voltages by setting up the 3-phase system in miniature on the a-c calculating board, applying faults of several types under different system conditions at several locations and actually measuring the recovery voltages. This method permits taking into account the effect of loads, ground and arc resistance, point of applying the fault with respect to the voltage wave, point of interrupting the current, effect of leaving the fault on the system for different lengths of time, effect of different fault locations, or practically any condition that could be experienced on an actual system in commercial operation.

It is proposed in this paper to present a method which extends the work previously done to allow a more general study of systems. The results of general analysis will be presented in a subsequent paper.

## General Discussion of the Recovery Voltage Phenomena

The problem of determining the recovery voltage of a system is merely that of finding the voltage-time curve for the transients in the system that follow the interruption of an arc path. The basic elements of the problem may be brought out by a discussion of figure 1. Assume that the system is subjected to a short circuit in an arc path at the point $F$ and that the current which flows is interrupted at a normal zero point of the current wave. The transient that follows the interruption of the current gives rise to an oscillation in the voltage which reappears across the arc path. If the insulation strength of this arc path when expressed in voltage and time is higher than the voltage produced by the system, the arc path will not be re-established and the fault current will be suppressed at the current zero assumed. The recovery voltage of this simple system may be calculated according to conventional methods. As illustrated in figure 2, the recovery voltage may be considered as the sum of 2 components: (1) a steady-state or forced frequency component, which is determined by the circuit constants and the generated voltage of fundamental frequency, and (2) a high or natural frequency component which is determined by the circuit constants of this system for free oscillation. The latter component is subject to an exponential decrement on account of losses which in the course of time reduce this component to zero. The current and the various voltages and their components for the simple system of figure 1 are illustrated in figure 2.

When a system with several meshes is considered, each mesh has its own steady-state and natural frequency components and these react on each other through their mutual couplings. The resultant recovery voltage curve, therefore, consists of the sum of a steady-state component and a number of natural frequency components, each of which may have different decrements. While the calculation of recovery voltage for extensive systems becomes quite complicated, it should not be considered something mysterious, since the basic phenomenon is quite simple as brought out in the discussion of figure 1.

It is desirable to review the character of recovery voltage from the standpoint of its practical application and to establish the meaning of the terms to be used in the subsequent discussion. For complicated systems, the recovery voltage-time curve may have quite an irregular shape, such as illustrated in figure 3. Curve $A$ applies to one hypothetical system where there is no residual charge left on the system and curve $B$ applies to another hypothetical system having a residual charge. The entire voltage-time relation is generally implied when the term recovery voltage is used. Recovery voltage is of importance depending on the closeness with which it approaches the insulation strength of the particular arc

path under consideration. The shape of this insulation recovery curve will vary for the different conditions of the arc path and particularly for the different arc interrupting devices. Some insulation strength curves may be of the shape illustrated by curve *C* of figure 3, which as drawn approaches the system recovery voltage curves near their crest. For such conditions the maximum recovery voltage and the time to crest represent the important part of this system recovery voltage-time curve. Another insulation recovery curve might be of the shape shown in curve *D* which comes closest to the system recovery voltage-time curve *A* at a point close to that of the maximum recovery voltage rate. There is also the possibility that the insulation recovery curve might be of the shape shown by curve *E* which contacts the system recovery voltage curve *A* at an intermediate crest between the point of maximum recovery voltage and the point of maximum slope.

## Part I. Analytical Methods for Calculating Recovery Voltage

There is now available considerable literature on the calculation of transients in circuits involving an a-c source and resistive, inductive, and capacitive branches. In general, the approach is to consider a current circulating in each mesh and to make these currents follow Kirchoff's laws for the transient conditions. Differential equations may be set up and the boundary conditions determined in line with the classical theory. The complete solution is complicated by the necessity of providing for (1) all the possible initial conditions of energy storage in each of the various circuit elements as well as for (2) the various natural frequencies of oscillation and for (3) the various rates of decrement. The mechanical labor of solution may be minimized by systematizing the process and an excellent reference is the work by Guillemin.[1]

*B*—Recovery voltage curve for system with residual charge

*RR*—Maximum recovery voltage rate for curve *A*

*C, D, E*—Insulation voltage recovery curves

**Figure 3. Comparison of system recovery voltage curves and insulation strength curves**

The conventional method of approach to a solution may be considered as a single-phase method in contrast to the polyphase method to be described subsequently. In the single-phase method the solution may be obtained by assuming a fictitious source of voltage equal in magnitude but of opposite polarity to the voltage existing in the system at the instant of arc suppression, this source being superposed on the actual system and its energy being dissipated through losses in the system. The circuit involves one phase of the power system with return through the neutral and the other 2 phase wires in parallel, and thus it becomes very complicated if many meshes are considered. Such a method has the disadvantage of employing circuits which are difficult to visualize and which will vary for each type of fault; for example, the circuits will be different for a line-to-line fault than for a single line-to-ground fault. Furthermore, the various steps of the solution are also difficult to visualize and the calculations must be carried through in a mechanical manner. In order to avoid a number of these objections a polyphase method utilizing symmetrical components is proposed.

From the foregoing it is apparent that for any particular application, the significant factor of the system recovery voltage may be defined in terms of a voltage magnitude and the corresponding time. It is, of course, possible to define the point of interest in terms of a voltage recovery rate and either the corresponding time or the corresponding voltage magnitude. The quantity "recovery voltage rate" by itself is obviously insufficient to define the significant points on either the insulation strength curve or the system recovery voltage curve. Since the term recovery rate is applicable to only a limited range of conditions its general use may become confusing and misleading. For these reasons it has seemed preferable to use the terms recovery voltage magnitude or merely "recovery voltage" and "time to crest" for defining the point of interest on the recovery voltage-time curve and this form of expression is adopted in this paper.

## Transient Analysis by the Method of Symmetrical Components

The application of the principle of symmetrical components to the solution of high frequency transients on polyphase systems constitutes an important step in the simplification of this problem. It will be recalled that steady-state solution of unbalanced faults on ordinary 3-phase power systems was found to be generally impracticable as long as "single-phase" methods of solution were employed. The introduction of the method of symmetrical components by the late Doctor C. L. Fortescue radically changed the status of this problem and the method has come into general use for a variety of applications subsequent to the introduction of the sequence networks. Similar simplification in the solution of high frequency transients is obtained through the use of symmetrical components. In this method the natural frequency components are themselves resolved into positive-, negative-, and zero-sequence components in a manner quite analogous to that employed in the analysis of the ordinary steady-state solution of unbalanced circuits at

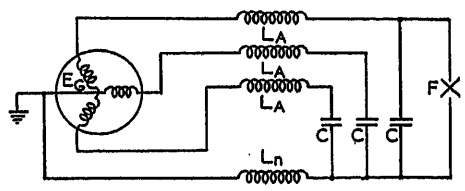

**Figure 4. Simplified 3-phase system subjected to a line-to-ground fault**

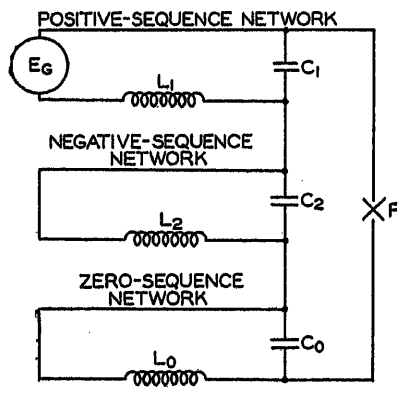

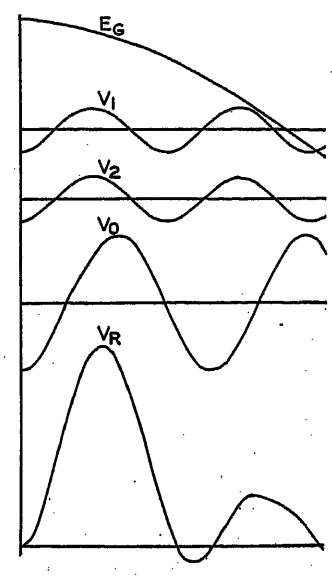

**Figure 5. Connection of sequence networks to simulate single line-to-ground fault. Opening circuit at F simulates clearing of the fault and recovery voltage appears at this point**

fundamental frequency. The advantage of resolving the natural frequency components into their respective sequence components is the same as with fundamental frequency, namely, that the components do not react upon each other in a symmetrical system. The boundary conditions for the natural frequency components are determined, of course, by the dissymmetry of the system occasioned by the fault itself.

In order to illustrate this method a relatively simple system, as shown in figure 4, will be considered. This system is assumed to have a positive-sequence generated voltage $E_G$ in the reference phase with capacitances and inductances in each phase and in the neutral as shown. For this example a fault of the single line-to-ground type is considered. The current is assumed to be interrupted at its normal zero point. The losses in the circuit are ignored and the fault current condition is calculated in the familiar manner making use of the sequence networks.

The manner of setting up the sequence networks for the ordinary circuits containing apparatus and transmission lines, including capacitances and loads is now well established.[2] For a single line-to-ground fault the 3 networks must be connected as shown in figure 5 in order to satisfy the requirements for this particular fault condition. Since by assumption the circuits do not involve loss the resultant current lags 90 degrees behind the voltage of the faulted phase. Consequently, the circuit is interrupted at the zero point of the current wave, the generated voltage on the faulted phase is a maximum, and the various capacitances associated therewith have their maximum charge; the sequence networks are isolated automatically and each oscillates according to its own natural frequency. In the course of time, such oscillations in an actual circuit would be damped out because of the losses. In the case of the negative- and zero-sequence networks, only the natural frequency oscillations are present; in other words, after the fault is removed there are no voltages and currents under steady-state conditions. In the case of the positive-sequence network, however, there is a steady-state solution because of the generated electromotive force and superposed on this is the free oscillation which is determined by the difference in voltage across the capacitances under fault conditions and the value which would be obtained under steady-state conditions. This difference in voltage sets up a free oscillation in the positive-sequence network which in the actual circuit would be dissipated by losses. The total voltage on the faulted conductor consists of several com-

$E_G$—Steady-state voltage
$V_R$—Total recovery voltage
$V_1$—Natural frequency component in positive-sequence network
$V_2$—Natural frequency component in negative-sequence network
$V_0$—Natural frequency component in zero-sequence network

ponents, as shown in figure 6. These include $E_G$, the steady-state voltage due to the fundamental system frequency; $V_1$, the voltage arising from the free oscillation in the positive-sequence network; $V_2$, the voltage arising from the free oscillation in the negative-sequence network; and $V_0$, the voltage arising from the free oscillation in the zero-sequence network. The sum of these voltages must be taken as zero initially in order to fit the fault condition. When the fault is removed these components oscillate according to their respective forced or natural frequencies and the recovery voltage is the sum of the several components and is plotted as $V_R$ in figure 6.

The use of the sequence networks to solve the transient oscillations makes it possible to obtain a better visualization of the phenomena taking place. The various sequence networks may have different natural frequencies of oscillation and different rates of decrement. These considerations make it clear that the shape of the actual recovery voltage curve is in general quite complex. The time to crest and the magnitude of this crest depend on the relation that these oscillating components bear to each other at that instant. Thus, if the several components are in phase the maximum crest is reached. If some of the components of considerable magnitude are in opposition when the remaining components reach their maximum value, the recovery voltage curve is considerably distorted and the crest may be relatively low.

## Representation of System Elements With Lumped Constants

The simple system of figures 4 and 5 can be extended readily to all systems with lumped constants. Question naturally arises as to the necessity for modifying the constants of the circuit elements for representation at high frequencies. Ordinarily these branches, such as machines, transformers, reactors, and capacitors can be represented by inductances or capacitances corresponding to their 60-cycle reactances. In the case of synchronous machines the reactance to be used in the positive- and negative-sequence networks is intermediate between the leakage reactance and the negative-sequence reactance and may be obtained by impressing high-frequency potential on the machine terminals. As the frequency of the impressed voltage is increased the equivalent inductance decreases because of eddy current effects. From the data available the frequency correction to apply to the 60-cycle negative-sequence reactance of the machine is shown in figure 7. The impedance at high frequencies is closely the same for both the positive- and negative-sequence components and, therefore, the same value may be used in both networks.

More accurate representation of the various circuit elements may be required in special cases, as for example, the case in which the recovery voltage is to be obtained on a bus with only the generator connected. For this case it is necessary to determine with some accuracy the capacitance of the bus and the distributed capacitance of the winding. Under such conditions the machine, transformer or reactor representation involves a problem quite similar to that discussed subsequently for circuits having distributed constants. Such refinement in apparatus constants is not required for the usual problem since the effect of these relatively small capacitances is negligible in comparison with the relatively large capacitances of transmission lines, but it is important for the special case of circuit breaker opening, since the analysis is usually made for the case involving opening the last circuit breaker on the bus section.

## Representation of System Elements With Distributed Constants

Special consideration is required for the representation of a system element having distributed constants, such as a transmission line. The actual transmission line has 3 phases, which may be considered as composed of an infinite number of sections, each with its own self and mutual series impedances and its own self and mutual shunt capacitances. It is possible to use the sequence representation so that the problem reduces from the 3-phase circuit to

that of 3 single-phase circuits with distributed constants, one for each sequence.

The typical case requiring consideration is shown schematically in figure 8 in which $L$ represents the inductance of the source and the square represents the transmission line. If the line were of unlimited length it might be represented by its surge impedance. However, in power work the transmission lines are usually too short to justify such an approximation for determining the maximum crest, although this representation is useful for obtaining the first crest after current zero. The magnitude of the recovery voltage for a particular case of a finite line charged through an inductive source has been calculated by the conventional wave theory and the results are shown in figure 9.

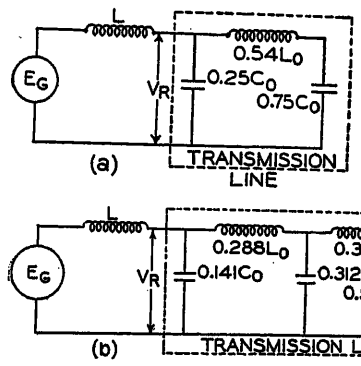

**Figure 11. Equivalent networks for representing transmission line with distributed constants**

(*a*) Single mesh equivalent circuit

(*b*) Two mesh equivalent circuit

$L_0$—Total inductance of line
$C_0$—Total capacitance of line
$L$—Inductance of source (not part of network for transmission line)

Such calculations entail too much labor for general use. Hence, it is desirable to represent the transmission lines by a suitable approximation in the form of an equivalent circuit. The approximation need not hold beyond the maximum overshoot and as a matter of fact it need not be accurate throughout this range if it is accurate in both magnitude and time for the particular point on the recovery voltage-time curve that requires consideration. An extremely simple equivalent circuit for transmission lines of finite length consists of an inductance and a capacitance connected in series across the circuit, the combination having the same natural frequency. The recovery voltage of such a circuit will have a time to crest which will be the same as that required for a wave to travel to the far end of the circuit and return.

A more accurate representation by means of equivalent circuits may be arrived at from a comparison of the frequency-impedance characteristics. A transmission line of finite length will have a frequency impedance curve, such as shown by the solid line curve in figure 10; the other curves show the frequency-impedance characteristics of the 2 equivalent circuits shown in figure 11. It will be noted that these circuits have frequency-impedance characteristics which are closely the same as that of the actual transmission line throughout a limited range of frequencies. The calculated recovery voltage curves for the 2 equivalent networks of figure 11 are plotted in figure 9 for convenience in comparison with the recovery voltage calculated by the wave theory. It will be noted

$L_0$—Total inductance of line
$C_0$—Total capacitance of line

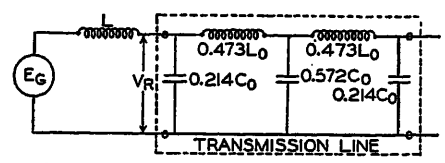

**Figure 12. Double-end equivalent network for representing transmission line with distributed constants**

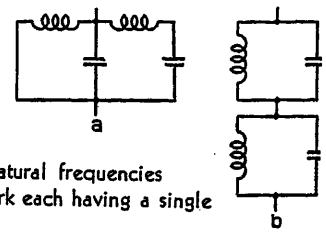

**Figure 13. Network transformations**

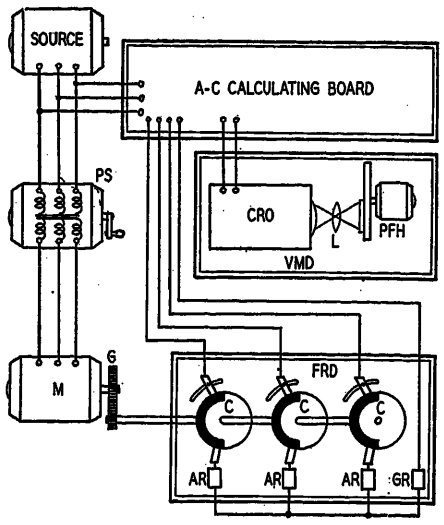
(*a*) Two mesh network with 2 natural frequencies
(*b*) Equivalent single mesh network each having a single natural frequency



that reasonably good approximation is obtained by these relatively simple equivalent circuits.

For more accurate representation of a transmission line, greater complexity in the equivalent circuit will be required. In general, these networks should be the same for both an open-circuited and a short-circuited receiver. Also, the equivalent circuit should be of the "double-end" type so as to facilitate the introduction as an element in the complete network. One of these double-end networks is illustrated in figure 12.

Another method of studying the equivalence of networks is to compare the simple equivalent circuit with the more elaborate circuit requiring a very large number of series inductance and shunt capacitance elements.

## Solution for Line-to-Ground Fault

The general method of setting up the equivalent circuits for each of the different sequences has already been described. For a line-to-ground fault the 3 sequence networks must be connected in series as shown in figure 5 in order to meet the requirements for the fault condition. When the fault is suppressed, oscillations will take place in each of the sequence networks. The natural frequencies of oscillation for each sequence network and their rates of decrement may readily be computed for the simple circuit shown in figure 5. For more complicated systems it is necessary either to transform the equivalent circuit to a more manageable form or to resort to the conventional solution using differential equations. When the equivalent circuit for each sequence network is not too complicated but is of a form similar to that shown in figure 13*a*, it is usually more convenient to transform it to the form shown in figure 13*b* which facilitates calculation of the natural frequencies of the individual sections. This use of equivalent circuits has been used by E. W. Boehne[3] for calculating recovery voltage by the single-phase method. The transformation depends upon the use of equivalent circuits having the same impedances at all frequencies and a number of such equivalent networks has been worked out by K. S. Johnson.[4]

**Figure 14. Schematic diagram for a-c calculating board method of determining system recovery voltage**

## Solution for Other Types of Faults

For other types of faults the same sequence networks may be used in various combinations. The method of connecting these networks varies with the type of fault and is the same as for the steady-state solution, for example, for the line-to-line fault the positive- and negative-sequence networks are connected in series with the normal direction of fault current flow reversed in the negative-sequence network. For the double line-to-ground fault the connection is the same as for the line-to-line fault except that the zero-sequence network is placed in parallel with the negative-sequence network. From this it is apparent that even the sequence method becomes involved for the more complicated types of faults. It has its greatest advantage in the solution of the line-to-line or line-to-ground faults.

## Limitations of Analytical Methods

Before taking up the ultimate method of solution proposed in the paper it is desirable to consider the further limitations of analytical methods. For example, the initiating transients arising from the application of the fault at voltage crest may not be dissipated before the fault current is suppressed and the resulting subsidence transients begin. In addition, the fault itself may not be single phase in character but may involve several transients, such as those that are incident to the simultaneous opening of each of the 3 poles of a circuit breaker. Further complication arises from the fact that the circuit opening is made through an arc which is not of linear resistance characteristic.

From the foregoing considerations it is apparent that the analytical method of solution is of restricted use. While the method of symmetrical components has simplified the problem for certain types of calculations, many limitations still remain. For this reason a more general method of solution is suggested using the a-c calculating board with connections corresponding to the analytical methods described.

## Part II. Determination of Recovery Voltage by A-C Calculating Board Method

In view of the limitations of the analytical solution of system recovery voltage transients, the method of setting up the system in miniature on the a-c calculating board is proposed. This method has opened the way for the first time to a general investigation of system recovery voltages, practically eliminating the mechanical labor and the human errors unavoidable in analytical solutions of such an involved and complicated nature. The arrangement of apparatus used in this method is shown schematically in figure 14 which includes:

1. The source
2. A-c calculating board
3. The fault representation device
4. The recovery voltage measuring device

The fault representation device includes means for controlling the point of application of the fault, its duration, and its resistance. To obtain a simple recording device, the transients are made repetitive in character with an

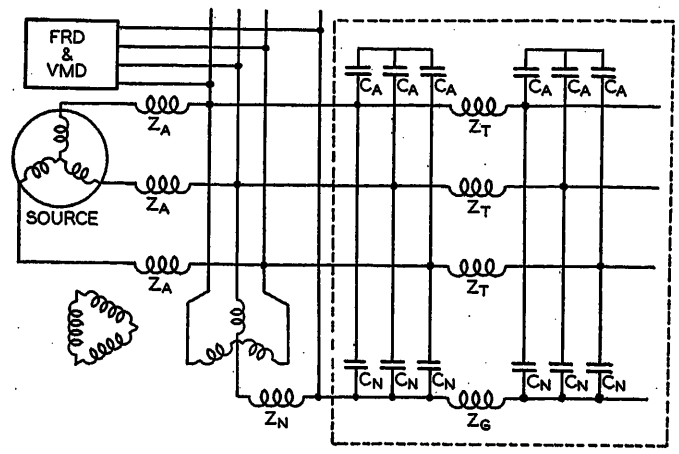

**Figure 15. Schematic diagram for the polyphase method of system representation on the a-c calculating board**

*VMD*—Voltage measuring device

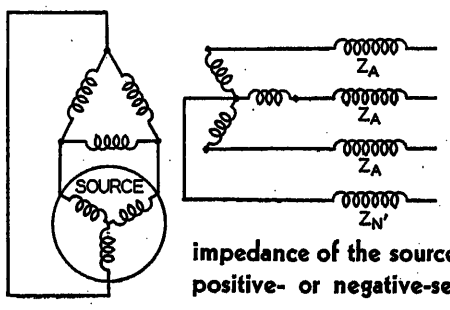

**Figure 16. Schematic diagram of simplified methods for representing power source applicable when zero - sequence impedance of the source is greater than the positive- or negative-sequence impedance**

intervening period of sufficient length that one transient does not interfere with the next.

## Connection of A-C Calculating Board

The a-c calculating board used in this investigation has been described in the literature.[5] Two methods of setting up the system on the calculating board are available, namely, (1) the sequence method and (2) the polyphase method. In the sequence method the system is set up in the form of the 3 sequence networks corresponding to the analytical solution of part I. This use of the a-c calculating board merely provides a means for minimizing the mechanical labor that would be required in the analytical method. In the polyphase method the system is set up with a 3-phase source and a 3-phase miniature system. The polyphase method has the advantage of corresponding more closely in form to the original system and it is more convenient since all the phase quantities are included directly in the setup and are available for various fault investigations without manipulation. However, in setting up either method the steps involve the same requirements in the miniature system, namely, that it shall have the same positive-, negative-, and zero-sequence constants for all of the circuit elements requiring consideration.

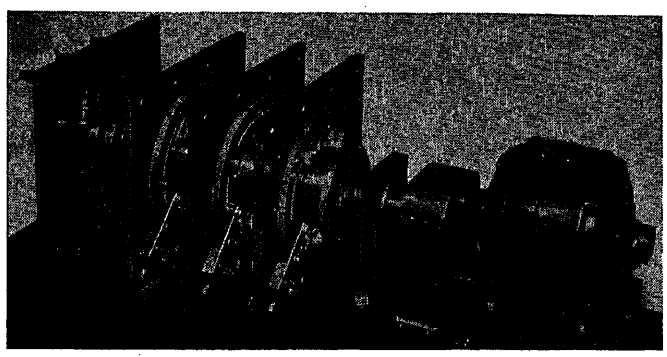

**Figure 17. Fault application device, shown schematically in figure 14**

In order to illustrate the polyphase method of setting up the system on the a-c calculating board, a more complicated system, such as shown in figure 15, is used. Incidentally, this system is sufficiently representative as to give a reasonably good solution for a large number of problems. Figure 15 applies to a system with a source of power consisting of a generator and step-up transformer, and a transmission line subjected to a fault as indicated. The branches $Z_A$ and $Z_N$ correspond to the generator and step-up transformer constants and the remaining branches correspond to the transmission line when represented by the equivalent $\pi$. The branches $Z_A$ represent the positive- or negative-sequence impedance per phase of the generator and transformer, and the branch $Z_N$ represents one-third of $Z_0$, the zero-sequence impedance of the transformer. If the zero-sequence impedance is higher than the positive-sequence impedance, the source may be represented by a grounded-star transformer with a neutral impedance as shown in figure 16. For this case, as in the previous case, the impedances $Z_A$ represent the positive- or negative-sequence impedance of the generator and transformer. For the neutral branch, however, the impedance $Z_N$ is equal to (1/3) $(Z_0 - Z_A)$. In the transmission line similar relations hold for the 3 sequence constants. The positive- or negative-sequence series impedance branch is equal to the impedance $Z_T$ in each phase, and the neutral impedance branch $Z_G$ is equal to (1/3) $(Z_0 - Z_T)$. The equivalent capacitance for each end of the $\pi$ representation consists of $C_N$ which is equal to the zero-sequence capacitance for each phase and $C_A$ which is equal to the difference between the positive- or negative-sequence capacitance and the zero-sequence capacitance for each phase.

## Fault Representation Device

The representation of the fault involves 2 elements.

1. The applicator by which the fault is applied and removed.
2. The representation of fault resistance characteristic.

The fault representation device is shown schematically in figure 14 and includes the commutator arrangement $C$ which consists of 3 separate elements, one for each phase. Each element has 2 brushes, one of which is adjustable. The commutator is driven by a synchronous motor connected to a phase shifter supplied from the same source as the a-c calculating board. The fault is established when 2 brushes make contact with the conducting section which spans half of the commutator periphery. The fault is removed when either of the brushes leaves the conducting section. Such a commutator may be built to permit individual control of the instant of application of the fault, but ordinarily it is sufficient to consider the fault applied simultaneously to the 3 phases and this may be done by a set of fixed brushes and a phase shifter. The duration of the fault is controlled by separate adjustment of the brushes which can be set to maintain the fault for different periods from a half cycle to several cycles of the fundamental. The gear, connected between the driving motor and the commutator, makes it possible to apply the fault alternately on a point on a positive wave and on the corresponding point on the

Solid curve—Characteristics of Rectox resistor for fault representation

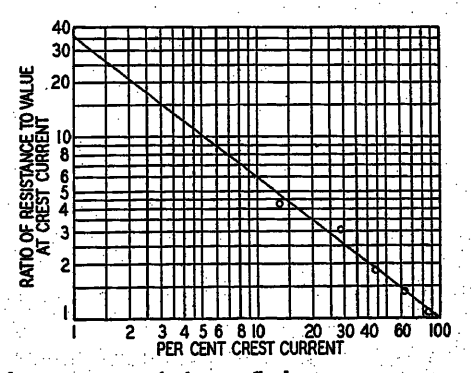

**Figure 18. Arc characteristic of deion flashover protector compared with fault representation device**

negative wave. The object of the gear is to avoid cumulative magnetizing action in the source. The fault applicator used in this investigation is shown in figure 17.

Consideration will now be given to the means for representing the fault and arc resistances. The first approximation of a fault is a resistance, which is of zero value while the current is flowing, and suddenly changes to infinite value when the current zero is reached. A second approximation of fault characteristics takes into account the tower footing resistance and the arc resistance. This

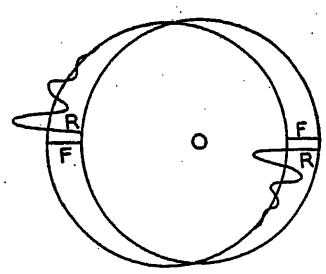

**Figure 19. Polar oscillogram of heavily damped oscillations**

*F*—Point of fault application
*R*—Point of fault suppression

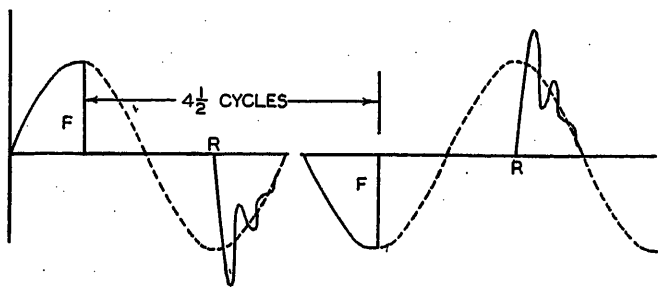

**Figure 20. Cartesian plot corresponding to figure 19**

*F*—Point of fault application *R*—Point of fault suppression

is, of course, readily represented by introducing an appropriate resistance in the fault path through the commutators and in the neutral as shown by the branches *AR* and *GR* of figure 14. A more accurate representation may be accomplished by the use of a resistor whose resistance-time curve would correspond to that obtained from the actual voltage across the arc and the current through it. Such a resistance curve could, of course, be obtained by a synchronously driven commutator which would vary the resistance throughout the cycle. A more convenient and practical device is the Rectox resistor which has approximately the desired characteristic. Two sets of Rectox units oppositely poled are connected in parallel to give the same resistance for either direction of current flow. This combination forms a resistor whose value is relatively low for high currents and relatively high for low currents. It is possible to choose the number of units to give a good approximation of certain arc characteristics throughout the principal part of the arcing period. The arc characteristics and Rectox approximation for a deion flashover protector are shown in figure 18. However, the representation at the end of the interval may not be accurate as the apparent resistance of the arc increases very rapidly at the instant at which the arc is suppressed. For this reason the Rectox resistor has been used in combination with the opening of the fault slightly ahead of normal current zero in order to leave a charge on the system.

## Recovery Voltage Measuring Device

The transient measuring device for viewing and recording the recovery voltages constituted a major problem. The requirements for the device included accurate response to the various high frequency oscillations, the imposing of small burden on the network always a factor in the use of miniature systems, and means for obtaining a visual trace and a permanent record. The magnetic oscillograph failed to meet all these requirements because an element designed for high frequency response, required a special hookup to avoid placing undue burden on the network. This pointed the way to the use of a cathode-ray oscilloscope which met all the requirements but that of recording. To overcome this difficulty the transient was made repetitive in character by the means just described. On this basis it was readily feasible to photograph the record appearing on the cathode ray screen. The arrangement of apparatus used in most of this work is illustrated in figure 14. The cathode-ray oscilloscope recorded the recovery voltage on its screen and this image was placed on a film through a suitable lens system. While it is possible to photograph the image using the cathode ray sweep circuit to provide the time scale, it was more practical to rotate the film by means of a synchronous motor thus obtaining a uniform time scale on an oscillogram of the polar form.

The type of record obtained for a highly damped transient is shown in figure 19 and the corresponding Cartesian plot in figure 20. The entire oscillogram repeats every 9 cycles and includes 2 applications of the fault indicated at the points *F* which are $4^1/_2$ cycles apart. The faults are impressed for $^1/_2$ cycle and the arcs are suppressed at the points *R* at which the recovery voltages begin to appear. The high frequency oscillations are superposed on the steady-state voltage as shown in the figures, and in this case are damped out in less than $^1/_2$ cycle. If the transient is not highly damped it may persist for many cycles. In general, however, the high frequency oscilla-

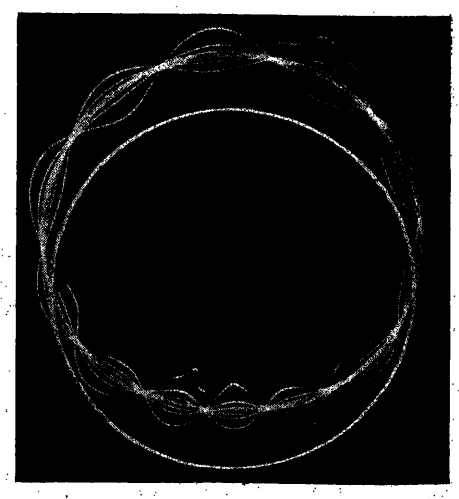

**Figure 21. Typical oscillogram of recovery voltage on a system with lightly damped oscillations**

138-kv system included measurements of recovery voltages with a cathode-ray oscillograph. For two of these tests involving a single line-to-ground fault, the system consisted of a generator and step-up transformers connected in star on the high voltage side and grounded through a 50-ohm reactor, and 39 miles of 138-kv line. Figure 22 compares the recovery voltages of these 2 field tests with results of calculations made for identical circuit conditions with the transmission line represented in one case by an equivalent "T" network and the other case by the equivalent network of figure 11*a*. The closeness of these checks made early in the investigation were very encouraging and greatly stimulated the work that followed.

Following the proposal of the a-c calculating board method and the development of the equipment previously described, it was of particular interest to compare results obtained with this method and results obtained by calculation. Figure 23 compares one of the calculated

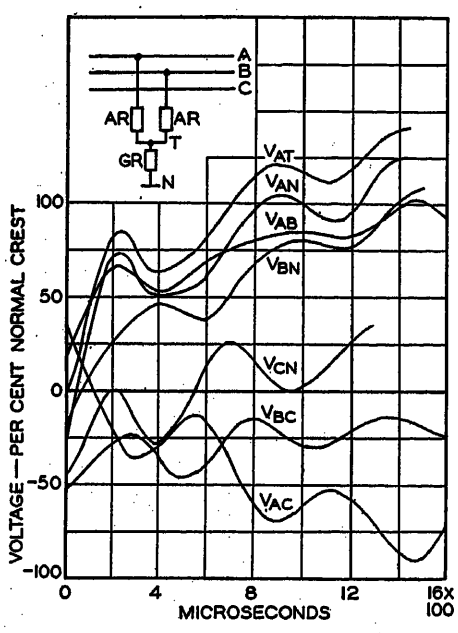
ing of the first phase at its normal current zero and this is followed by a similar adjustment for the second phase.

## Part III. Application of A-C Calculating Board Method and Comparisons With Analytical Solutions and Field Tests

It is now of interest to compare the recovery voltages as obtained by the analytical method and the a-c calculating board method directly with cathode ray oscillograms of tests made on actual systems. It is beyond the scope of this paper to give results of general investigations of system recovery voltage. A few illustrations will be given to show the range of use of the a-c calculating board in analyzing some of the factors.

It was recognized throughout this work that the results would only be of academic interest unless the solutions by the proposed methods provided a satisfactory check with the results of actual field tests. Some tests[6,7,8] made on the Indianapolis Power & Light Companys' curves of figure 22 with the recovery voltage measurements from the a-c calculating board using the alternative forms of connection. It will be observed that close checks are obtained between field tests, analytical solutions, and the a-c calculating board solutions.



The a-c calculating board method provides an ideal means for carrying out general studies of system recovery voltage. It is, however, beyond the scope of this paper to present results of work along that line. It is pertinent, nevertheless, to discuss the range of application of the a-c calculating board method in this study of the various factors entering into the recovery voltage problem. For this purpose a few illustrations are given to show the ways in which these factors may be studied.

It is of general interest to study the effect of applying the fault at different points on the voltage wave. With the a-c calculating board set up by the 3-phase method to represent the Indianapolis Power & Light Company system, a single line-to-ground fault was applied before voltage crest, at voltage crest, and after voltage crest and was interrupted at normal current zero. The results

of this study are shown in figure 24. Similar studies were made for the fault applied at the voltage crest and the current interrupted before, at, and after the normal current zero. The results of such an investigation are shown in figure 25. These results provide an explanation of the familiar fact that interrupting devices tend to operate at normal current zero. They illustrate further the difficulties of attempting to interrupt a circuit in less than one-half cycle.

The effect on the recovery voltage of varying the duration of the fault is shown in figure 26. This comparison brings out the fact that the shorter the duration of the fault the more important will be the results of the initiating transients on the recovery voltage.

The effects that arc resistance has on the interruption problem have always been of interest. Figure 27 shows the effects of adding different tower footing resistances of fixed resistance values as well as the effect of adding a resistance of varying value, such as shown in figure 18, to simulate the arc. This study was made for a 138-kv

impedance-grounded system with 90 miles of line, the system being capable of supplying short circuit current of 4,000 amperes at the sending end.

In order to simulate arc and fault characteristics in a more accurate manner for the condition in which a residual charge is left on the system, tests were made with the Rectox resistor in the circuit to simulate the arc throughout most of the cycle and the circuit was opened slightly ahead of current zero to simulate the very abrupt change of resistance at current zero. Figure 28 shows the results of a test which simulate a deion flashover protector when interrupting its full current rating.

The effect of load on the recovery voltage can readily be studied on the a-c calculating board and figure 29 shows a comparison of recovery voltage for zero load and for full load on the 90-mile 138-kv system.

It is of interest to have a knowledge not only of the voltage on the faulted conductor but also on the other conductors to neutral as well as between conductors. Figure 30 shows transient voltages for the 90-mile 138-kv system when clearing a line-to-ground fault on phase *B*.

On account of the complexity of the problem it has been practically impossible to get a co-ordinated picture of the transient voltages on the various conductors to ground and from conductor to conductor for a double line-to-ground fault condition. The a-c calculating board method has given a relatively simple approach to this problem and results of such a study for the 90-mile 138-kv system are shown in figure 31. Only the sections of the various transient voltage curves which are of an abnormal nature are shown, the plot starting at an arbitrary zero time in order to simplify the figure.

## Conclusions

1. The symmetrical components method proposed constitutes a simplification of the analytical solutions.

2. The a-c calculating board method is a practical means of determining the electrical transients of systems.

3. The combination of these methods has for the first time opened the way to a systematic general investigation of recovery voltage transients and related problems.

# Vibration-Measuring Instruments

## Fundamental Considerations in Their Design

By C. D. GREENTREE
ASSOCIATE AIEE

## Synopsis

A general-purpose wide-range high-precision vibration-measuring instrument must embody several fundamental design requirements which determine the useful frequency range, the accuracy of measurement, the intensity of vibration to which it can be applied, and the effect of the instrument on the vibrating body.

In this paper the advantages and disadvantages of certain mechanical and electrical detecting and amplifying systems for the measurement of vibration amplitude, velocity, and acceleration, are discussed in the light of their design requirements.

A vibration generator capable of producing sinusoidal vibrations over a wide frequency and amplitude range, and a set of vibration standards with which the vibrations produced can be accurately determined, are also described.

In conclusion, criteria for evaluating the performance of vibration measuring instruments of different types are suggested.

AN ever-growing demand for smaller and more accurate vibration measuring instruments has intensified design and development activities in this direction. This increased interest is due in part to the destructive possibilities of vibration on modern high-precision machinery and in part to an awakened recognition of the tremendous nuisance effect of unconfined vibrations.

The interest thus aroused has lead directly to more exacting specifications on the part of those who purchase vibrating or rotating equipment. To meet such specifications has required vibration instruments having increased sensitivity, greater portability, and broader operating ranges, which can be applied to ever-widening fields of investigation.

The general term "vibration instruments" is capable of considerable division and subdivision. The first broad classification can be labeled "precision measuring" as distinct from "vibration detecting." By vibration detecting is meant a device that will simply show that vibration is present or is not present. The mechanical or electrical output from such an instrument may be proportional to the relative amount of vibration over a limited frequency range and still be far from the precision concept.

Precision measuring vibration instruments can in themselves be roughly separated into 2 broad application classes. In one group can be placed all those highly technical and very special instruments built and designed to emphasize or surmount unusual vibration requirements. Practically every extensive vibration investigation program will require one or more of these special instruments, and in general a skilled vibration engineer is necessary to use them successfully. In the other broad division can be included all the general purpose devices. These are characterized by broad operating range, relatively low cost, and a susceptibility to particular adaptations, such as, permanent mounting, recording, and telemetering.

## Types of Instruments

Subsequent discussion will be confined to these general purpose precision measuring vibration instruments. Another subdivision into the 3 main aspects of vibration is required. Three different types of instruments are required for measuring amplitude, velocity, and acceleration. Frequency may be considered more of a condition than an aspect. The first type measures the double amplitude of vibration, or the amount of physical displacement of the vibrating body independent of the frequency or rate of moving.

A velocity type of instrument measures the product of vibration frequency and amplitude, or the rate of vibratory motion. This type of measurement is often convenient, since the vibration energy of the moving body is proportional to its velocity squared. Acceleration depends, of course, on the change in the rate of movement and an acceleration measuring device has an output proportional to the product of amplitude times frequency squared.

These 3 types of instruments are all subject to certain limiting mechanical factors. Some of the most important of these factors are:

(*a*) Establishment of a point stationary in space against which to measure
(*b*) Low natural frequency
(*c*) High structural resonance
(*d*) Ability to follow large accelerations
(*e*) Small effect on vibrating body
(*f*) Measurement in any direction
(*g*) Light weight and portable

## Mechanical System

Perhaps the most fundamental requirement of a general purpose vibration instrument is the creation of a

A paper recommended for publication by the AIEE committees on instruments and measurements, and electrical machinery. Manuscript submitted March 23, 1937; released for publication April 10, 1937.

C. D. GREENTREE is engineer on development work with the General Electric Company, Schenectady, N. Y.

1. For all numbered references see list at end of paper.

point or body stationary in space relative to which the vibratory motion can be measured. A vibrationless object, which can be used as a reference base, is seldom found ready to hand on the job, and usually is too costly to warrant construction. The establishment of such a stationary mass can be obtained in instruments, by the compliance coupling of a mass to the vibratory motion. The fundamentals of such a scheme are shown in figure 1*a*. The stationary mass $M$ is supported from the moving mechanism $R$ which is in contact with the vibrating body $B$, by the coupling spring $S$. The direction of vibration is shown by the double-headed arrow marker. At the point $A$, between the end of the moving mechanism and the stationary mass, any one of several mechanical or electrical methods for obtaining a measure of the relative motion between the 2 parts can be interposed.

Figure 1*b* shows the electrical equivalent of this mechanical system. The current $i_1$ represents the vibratory motion applied to the instrument. Neglecting $L_1$ and $C_1$ for the moment, the current $i_1$ will divide between $C_2$, representing the compliance of the coupled system, and $L_2$ representing the mass $M$. When the frequency of the applied current is more than 5 times the resonant frequency of the network including $L_2$ and $C_2$, the impedance of $C_2$ has become very small compared to the impedance of $L_2$, and substantially all the current flows through $C_2$.

The coupling spring represents the heart of the mechanical system. Under the action of gravity or inertia, a given mass will oscillate on a given spring at a certain natural frequency. Conversely, if the end of the spring is driven by a vibration having a frequency equal to or nearly equal to the natural frequency just determined, a condition of resonance is set up and the mass, instead of remaining stationary in space, will tend to vibrate at tremendous amplitudes limited only by the friction of the spring and the inertia and friction of the supporting hand and arm in which the mass may be held. Mechanical system resonances are, in general, sharply peaked, and experience has shown that the mass will remain substantially stationary when the end of the spring is driven at a frequency from 4 to 5 times the natural frequency of the system. In a great deal of vibration work, it is desirable to be able to measure down to 10 vibrations

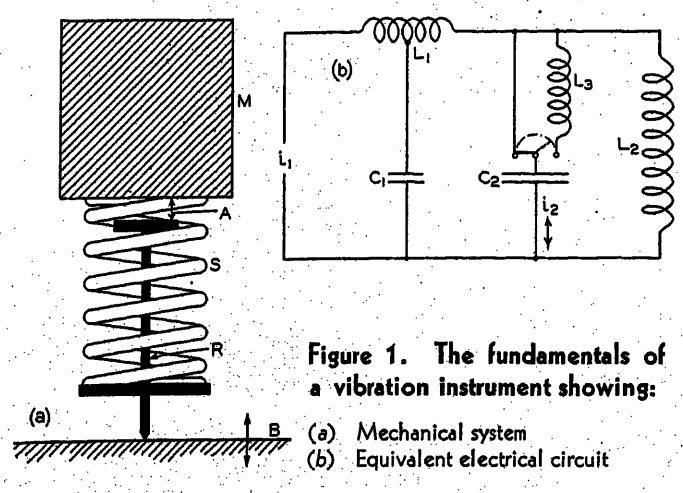

**Figure 1. The fundamentals of a vibration instrument showing:**

(*a*) Mechanical system
(*b*) Equivalent electrical circuit

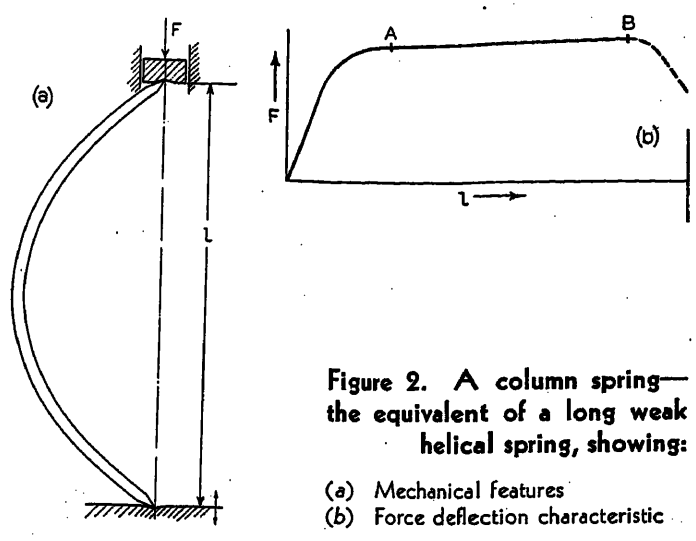

**Figure 2. A column spring—the equivalent of a long weak helical spring, showing:**

(*a*) Mechanical features
(*b*) Force deflection characteristic

per second, equivalent to 600 rpm. This means that the natural period of the mass on its coupling spring should be from 2 to $2^1/_2$ vibrations per second.

The formula[1] for the natural frequency of such a mechanical system is given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{Kg}{W}} \text{ or } K = \frac{W}{g}\omega^2$$

where

$f$ = vibrations per second
$W$ = weight
$g$ = gravity acceleration
$K$ = spring constant of coupling spring

If $f$ is to be small, 2 to $2^1/_2$ vibrations per second, and $W$ must also be small, for lightness and portability, it is apparent that $K$ will be small, representing a weak spring. To avoid fatigue and failure due to excessive stress in the outer fibers of the spring, it will be necessary to make this spring relatively long. A long, weak spring is difficult to contain in a small space.

Thus, one of the most active lines of endeavor in the design of vibration instruments has been to produce the equivalent of a long weak spring, which can be contained in a small space and which will not permit too great relative movements between the mass and the driving mechanism.

One such equivalent is shown in figure 2*a*. When a force, continually applied along the original major axis of the column, has compressed the spring beyond a certain point, further compression increases the spring resisting moment arm[2] and the external eccentric loading moment arm by approximately the same amount. This means that a very small change in pressure will cause a relatively enormous change in effective length of the column. The force versus effective length characteristic of such a spring is shown in figure 2*b*. The spring constant of the column, as shown by the slope of this curve between the points $A$ and $B$, is very small.

Another method[3] for supporting a mass on springs at a low natural frequency is shown in the negative compliance system of figure 3*a*. Movement of the mass toward the left causes a compression of the spring $A$ and

**Table I. Vibration Amplitudes and Velocities Corresponding to an Acceleration of 25 Times Gravity**

| f = Vibrations per Second | D = Double Amplitude (Displacement) in Inches | V = Maximum Velocity (Inches per Second) |
|---|---|---|
| 10 | 4.89 | 154 |
| 60 | 0.136 | 25.6 |
| 200 | 0.0122 | 7.65 |
| 1,000 | 0.000489 | 1.54 |
| 4,000 | 0.0000805 | 0.385 |

a lengthening of the spring $B$, thus producing resisting forces vectorially represented by $A$ and $B$ in figure 3*b*. At the same time, the ends of the knife-edge links bearing on the mass are displaced toward the left. The pressure of the springs $F$-$F$ tends to continue the movement of the mass toward the left. By the proper adjustment of the relative compression forces exerted by all the springs, the component of the knife-edge linkage forces $F$, which opposes the resultant of forces $A$ and $B$, can be made to balance or very nearly balance the resisting force of spring $A$ and spring $B$. This will hold, of course, only so long as the angle $\theta$ is small so that this opposing component is substantially equal to $2F\theta$. The force deflection characteristic of this system is shown in figure 3*c*.

## High Structural Resonance

The measurement of vibrations of high frequency, requires a mechanical transmission path from the point at which the vibration is contacted to the point within the instrument at which the measuring takes place, which will be free from structural resonances at any frequency lower than the highest frequency to which it is desired to measure. Structural resonance will occur at that frequency at which the distributed mass of the moving system, as represented in the equivalent electrical circuit, figure 1*b* by $L_1$, resonates with the distributed compliance, as represented by the lumped value $C_1$. When this occurs, the current through capacitor $C_2$ is no longer a true indication of the current $i_1$.

The surmounting of this difficulty requires a stiff yet light transmission system which can be obtained by keeping the transmitting member as short and small as possible and utilizing an inherently high resonance shape, like a rod or tube driven longitudinally.

## Ability to Follow Large Accelerations

In order to meet the prerequisites for a wide range general purpose instrument, it must be possible to hold the spring-coupled contact rod in contact with the vibrating object during accelerations many times that of gravity. Experience has shown that an ability to follow up to an acceleration of 25 times gravity would be generally acceptable for most types of work. In certain cases, such as the vibrations of an unbalanced high-speed spinning motor shaft, which sometimes exceeds 70 times gravity, much higher accelerations may be encountered. Table I shows an acceleration of 25 times gravity expressed in terms of double amplitude of vibration at several different frequencies.

Applying the known equation,

$F = MA$, or $A = F/M$

where

$A$ = acceleration
$F$ = force
$M$ = mass

to figure 1*a*, it is evident that for $A$ to be large, $F$, the pressure exerted by the coupling spring, must also be large, and the mass of the moving mechanism, $R$, must be small. In the equivalent electrical circuit of figure 1*b*, $L_1$, which represents the mass of the moving mechanism, must be small.

## Small Effect on Vibrating Body

Since a general purpose instrument should be applicable to any vibrating body from a massive turbine shell down to a $^1/_{100}$ fractional-horsepower motor frame, it is desirable to have the moving mechanism of the instrument produce as little effect as possible on the vibrating body. This is particularly true when dealing with light bodies which are vibrating at, or near, resonance. When the contact rod is pressed against a vibration, the mass of the moving mechanism, and part of the mass of the spring, are effectively coupled to the vibrating body. Thus, the smaller the mass of the moving system the smaller will be the effect on the vibrating body.

In addition to this mass loading condition, the pressure of the coupling spring, acting through the contact rod, may set up stresses in the vibrating body which will materially affect its vibratory motion. This is especially true in the case of resonant vibration of thin bodies such as the walls of an air duct.

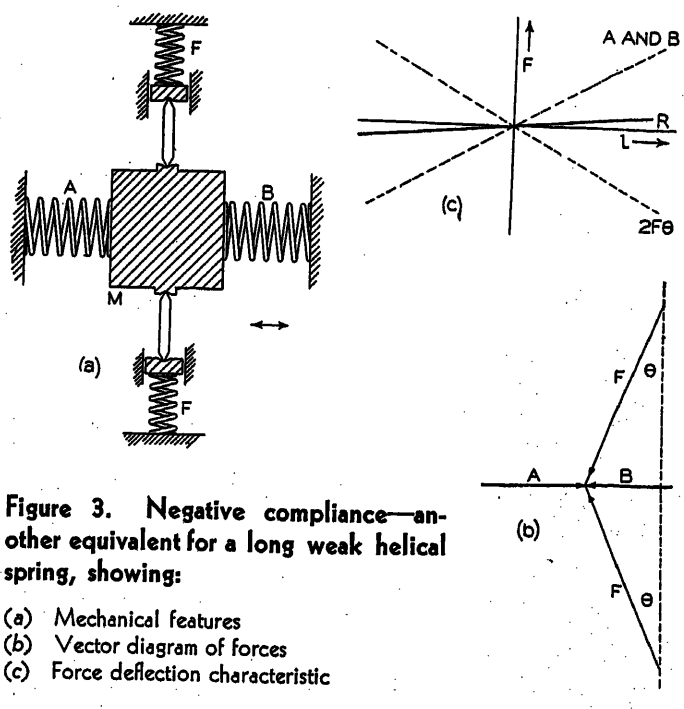

**Figure 3. Negative compliance—another equivalent for a long weak helical spring, showing:**

(*a*) Mechanical features
(*b*) Vector diagram of forces
(*c*) Force deflection characteristic

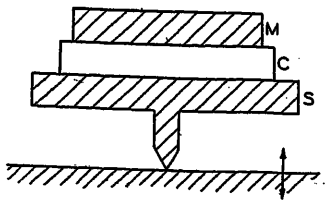

**Figure 4 (above). A piezoelectric crystal used for the measurement of vibration acceleration**

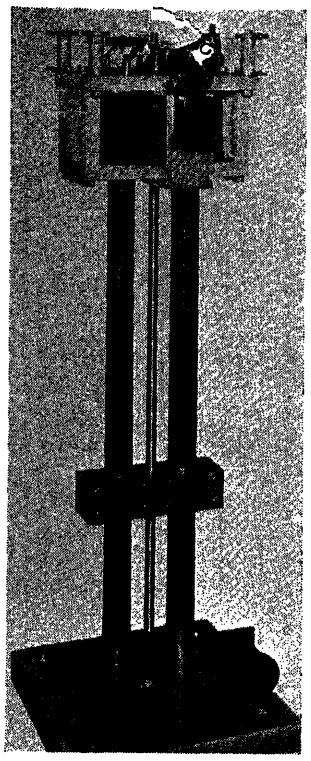

**Figure 5 (right). Vibration generator**

Both the ability to follow a large acceleration and the attainment of a small effect on the vibrating body call for a moving mechanism of small mass, but in the former a strong spring is needed while the latter requires a weak one. One way to obviate this difficulty is to provide an adjustable spring or springs, the pressure of which can be increased when it is desired to measure large accelerations. In general the acceleration of small bodies under resonance conditions will be small, thus permitting the use of a relatively weak adjustment of the spring. On somewhat larger bodies which are capable of handling much greater vibration energies, and hence producing larger accelerations, it is permissible to increase the spring pressure.

## Sensitivity

Modern requirements as written into rotating machinery specifications sometimes call for the limitation of vibration amplitudes to values less than 0.0001 inch. In addition to these mechanical requirements, it must be remembered that the awakened interest in noise calls for vibration measuring instruments of even greater sensitivity. A vibration amplitude of one millionth of an inch at 1,000 vibrations per second will produce an appreciable noise. The attainment of such sensitivity depends upon the electrical or mechanical measuring means which are interposed between the stationary mass and the moving mechanism of figure 1*a*.

## Mechanical Measuring Systems

A load, small in comparison with the inertia of the stationary mass of figure 1*a*, can be connected between the moving mechanism and the mass. This load, for example, may be an amplifying mechanical lever, gear train, or light-beam system adapted to greatly magnify the vibratory motion.

This load, in effect, is simply a continuation of the mechanical system already outlined, and its parts are subject to similar requirements of light weight, structural stiffness, etc. Referring to figure 1*b* the moving mass added by this load will increase $L_1$, while the lack of stiffness in its parts will increase $C_1$, thus increasing the effect on the vibrating body and reducing the ability of the instrument to follow large accelerations.

The reaction of the moving parts on the stationary mass $M$, to which they are connected, can be represented by the addition of an inductance $L_3$ in series with $C_2$. When $L_3$ is an appreciable fraction of $L_2$, which it may be when the lever amplification is large, some part of the current $i_2$ will shunt through $L_2$ and be lost for measurement purposes. Under these conditions $L_2$ is no longer stationary in space, but has some movement.

It is almost impossible to construct a mechanical system of large amplification which will at the same time be rigid and have small inertia. In addition the friction and lost motion at the joints will seriously limit the accuracy of the instrument.

Until ways are found to circumvent this practical difficulty, purely mechanical systems will continue to be restricted to vibrations of relatively low frequency, of the order of 50 vibrations per second or less, and amplitude measurements of the order of one mil or larger.

## Electrical Measuring Systems

By making the stationary mass $M$, figure 1*a*, a magnet which surrounds a coil rigidly attached to the moving mechanism, it is possible to generate a voltage proportional to the velocity of the vibrating body and at the same time add very little mass to the moving mechanism and introduce but a very small amount of reaction on the stationary mass. The inherent sensitivity of this electrical method depends, like all a-c generators, on the establishment of a high flux density and a high coil space factor. Furthermore, the enormous amplification obtainable from vacuum-tube amplifiers has no deleterious effect on the fundamental mechanical system, nor are serious frequency limitations introduced by the amplifying means.

This system is admirably adapted to the measurement of vibration velocity. It can, by the use of a frequency analyzer, be used to measure amplitude, but the process is apt to be laborious, especially when dealing with non-sinusoidal vibrations.

An electromechanical method for the direct measurement of acceleration is shown in figure 4. The mechanics of this system differ from those shown in figure 1*a*. A piezoelectric crystal $C$ is cemented to a stiff member $S$ which can be held in contact with the moving body, and a heavy metal block $M$ is cemented to the back of the crystal. Under conditions of vibration the block $M$, due to inertia, will produce alternating pressure and tension on the crystal. The amount of pressure and tension depends directly on the mass of the block $N$ and the acceleration of the vibration.

The voltage, proportional to pressure, generated by the piezoelectric crystal, can be amplified in the same

manner as the output of the velocity type of instrument.

In contrast to the amplitude and velocity instruments the whole mass of this acceleration device, including the hand which holds it in contact, will appear as a load on the moving body, thus reducing the maximum acceleration to which it can be applied. This difficulty can be surmounted in part by making the crystal and the mass $M$ very small.

The measurement of velocity or amplitude by this crystal method requires, respectively, a single or a double integration of the output.

## Vibration Testing Equipment

For the design and development of vibration instruments, it is vitally necessary to have a known controllable source of sinusoidal vibration. A great deal of time and effort have gone into the production of the vibration generator shown in figure 5. The output from a beat-frequency oscillator is stepped up by means of a 250-watt power amplifier and fed to a specially constructed moving coil which operates in an electromagnet field in the same manner as a loudspeaker. This edgewise-wound aluminum driving coil is capable of dissipating the full 250 watts of power at elevated temperatures. The motion of the coil is transmitted through a steel cone to the driving rod which projects from the top of the generator. The whole moving system is suspended in the air gap by means of steel piano wires under tension. Objects to be tested rest on, or are bolted to, this driving rod.

Such a generator is capable of producing amplitudes up to $^1/_4$ inch at vibration frequencies from 10 to 200 per second. At higher frequencies, up to 3,000 vibrations per second, proportionately smaller amplitudes are obtainable. Above 1,000 cycles the driving rod is locked to the resonance rod which extends downward between the supporting pillars. This resonance rod can be solidly clamped to the supports at any point throughout its length. When it is desired to vibrate the driving rod at say 2,000 vibrations per second the resonance rod is clamped at that length at which the natural longitudinal resonant frequency of the rod and driving mechanism equals 2,000. Two-thousand-cycle power applied to the driving coil will now produce relatively large movements of the driving rod. The amplitudes attainable are limited mainly by the internal friction of the resonance rod and its associated structure. Accelerations exceeding 70 times gravity have been measured and these when using only a small part of the total available power.

## Vibration Standards

Accurate determinations of the vibrations produced by this generator are obtained by means of primary and secondary standards. The secondary standard of frequency, the beat-frequency oscillator, can be checked when desired against primary frequency sources.

Amplitudes greater than 0.0005 inch are measured with a microscope equipped with a filar micrometer eyepiece. A spot of light reflected from a point on the moving generator drive rod produces a bright line in the microscope field. The length of this line, which is the amplitude of vibration, can be measured with great accuracy.

The determination of amplitudes below the microscope range is accomplished in 2 ways. A coil rigidly attached to the upper end of the drive rod, and partaking of its motion, generates a voltage by interaction with the surrounding field from a permanent magnet. This voltage is proportional to the velocity of vibration. By means of a high-gain amplifier, very small velocities of the driving rod can be measured. The calibration of this tertiary working standard coil and amplifier can be checked at one end of the amplitude range with the microscope, and at the other end by means of an acceleration device dependent on the constant of gravity.

A single point check can be made in a more fundamental manner. A hardened steel ball set on a hardened steel plate attached to the driving rod, will maintain contact with the plate when the acceleration of the driving rod is less than gravity. By passing a small current between them it is possible to accurately determine the exact point at which the driving rod reaches gravity acceleration, and the ball loses contact with the plate. At 2,000 vibrations per second this will occur at an amplitude of $1 \times 10^{-5}$ inches, approximately $^1/_{50}$ of the amplitude which can be measured accurately with the microscope.

## Conclusions

1. The growing need for general-purpose wide-range high-precision vibration measuring instruments makes it desirable to establish a systematic method of evaluating the performance obtainable from different types of instruments.

2. Three separate instruments or an instrument with 3 adjustments are required to measure the 3 different aspects of vibration; i.e., amplitude, velocity, and acceleration.

3. The natural frequency of the mechanical coupling system should not be greater than $^1/_4$ of the lowest frequency it is desired to measure.

4. The frequency of moving structure resonances should be considerably higher than the highest frequency to be measured.

5. The instruments should be capable of measuring vibration accelerations as high as 25 times gravity and should not have any large loading effect on the vibrating body.

6. Existing mechanical vibration amplitude measuring systems have undesirable frequency and sensitivity limitations.

7. Electrical generating and amplifying systems are well suited to the measurement of vibration velocity.

8. Wide range vibration generating equipment and accurate calibration standards are necessary for the development of high-precision vibration-measuring instruments.

# Basic Impulse Insulation Levels

A Report* of EEI-NEMA Joint Committee
on System Insulation Co-ordination**

AS A RESULT of a great deal of operating experience and from a survey of the then current practice as regards insulation of high-tension equipment, it began to be evident some 9 years ago that too little, if any, attention had been paid to co-ordination of insulation in power systems. Apparatus was being built to specifications which were primarily formulated on a 60-cycle basis, with consideration given mainly to the ability of the apparatus to withstand 60-cycle voltages and almost no consideration to impulse strength. Further, very little consideration was given to insulation margins between the different types of apparatus used on the same system voltage. This was first brought to the attention of the membership of the AIEE in 2 papers presented some 9 years ago.

The subject of insulation co-ordination thus brought into the open, was discussed rather extensively in committees by users and manufacturers and before the Institute for the next 2 or 3 years. Very little progress was made, however, owing to the complexity of the problem and the fact that several different industry interests were involved. Eventually this was recognized, and this led to the formation in 1931 of a joint NELA-NEMA committee to act upon the entire broad subject. The work of the NELA group was transferred to the Edison Electric Institute group when it was formed in 1933.

## Purpose and Scope of the Committee

When active work was started on this subject in 1931, the following statement of principles was made by the NELA (now EEI) group.

"The co-ordination of insulation involves 3 steps:

1. Establishment of insulation levels.

2. Specification of insulation strengths of all classes of equipment in establishing insulation levels.

3. Allocation of the insulation levels to the nominal system voltages taking into account all operating and environmental conditions."

## Activities of Committees

Without going into the details of the various meetings held and the subjects discussed, progress in the work took the following form.

1. It was generally agreed that the 60-cycle basis was not adequate alone for establishing insulation levels.

2. On account of the lack of a suitable agreed-upon yardstick with which to measure voltage levels, an air gap was at first considered, it being the best means available at that time. This gap initially took the form of a so-called edge gap, and later became the rather well-known rod gap, having definite limitations of spacing and physical arrangement.

3. Recognized testing laboratories of manufacturers and others were not in agreement on voltage flashover values of standard every-day types of equipment such as suspension insulators, bus supports, bushings, insulators, etc. This disagreement covered not only the field of 60-cycle voltage measurements but also that of impulse voltages. A so-called interlaboratory group was, therefore, formed to work on this problem and reach an agreement on proper values for similar apparatus. The work of this committee has been carried on carefully and persistently until at the present time the hoped-for agreement has been reached, within reasonable tolerances of measurement, on a great deal of electric equipment and on gaps. One paper has previously been published[1] giving results of this work. Also, a paper is now being presented[2] by the interlaboratory group giving agreed-upon flashover values of insulators and gaps.

A subcommittee was also appointed to investigate the existing practice of insulation of lines and equipment in the operating companies with the idea that such data would serve as a basis for setting up practical, workable, and effective levels of insulation in carrying out the first statement of principles given above.

This subcommittee spent a great deal of time and effort

in collecting and correlating these data, keeping in mind that the final levels selected must be based on practical as well as theoretical considerations. Within the last few months it finally agreed upon a set of basic impulse insulation levels utilizing as steps the preferred voltage classification adopted by NELA.[3] This series of basis impulse insulation levels adopted by the joint committee in January 1937 is presented in table I.

It will be noticed that the table gives the basic impulse levels for each "maximum rated voltage classification." In the lower range of voltages, this classification differs slightly from the preferred voltage ratings previously adopted by NEMA in the publication referred to above, but the steps given in table I are considered advisable in the light of the fact that present-day transformers in that range are specified in terms of those voltages.

It will be further noted that a fundamental and very important change has been made in this table, in that basic impulse insulation level is definitely expressed in terms of voltage. This voltage is the crest voltage of a $1^1/_2 \times 40$ positive wave which will just cause flashover on the tail of the wave when impressed on the so-called standard rod gap having $^1/_2$-inch square-cut electrodes. The gap spacings corresponding to these voltage values are given in the third column. These rod gap spacings are given for reference only, the basic level being crest kilovolts in column 2.

## Future Work

The first step in the co-ordination of insulation has therefore been finished and the second step, *viz.*, "Specification of insulation strengths of all classes of equipment in the established insulation levels," is now ready to be undertaken. This work has actually been begun since a subcommittee of the joint committee has been appointed and is working on this part of the program.

Now that the above insulation levels have been agreed upon, it is expected that more rapid progress will be made in carrying on the work still to be done. As the work progresses, it is planned to officially release periodically to the engineering field the findings and recommendations of the joint EEI-NEMA committee on system insulation co-ordination.

# Flashover Characteristics of Rod Gaps and Insulators

**A Report by the Subcommittee* on Correlation of Laboratory Data of EEI-NEMA Joint Committee on Insulation Co-ordination****

THIS REPORT has been written to present the agreed upon impulse and 60-cycle flashover values for rod gaps and suspension line insulators, together with a method of making correction for variation in humidity. The laboratory work and correlation upon which these data are based was done by the subcommittee on correlation of laboratory data* of the joint EEI-NEMA committee on insulation co-ordination. The joint committee authorized the publication in ELECTRICAL ENGINEERING of this work through a paper sponsored by the AIEE subcommittee on lightning and insulators. This makes the information more generally available to the the industry for use in connection with the general problem of insulation co-ordination.

## General

With the advent of impulse testing, it was immediately apparent that the flashover values given out by various laboratories for the same test piece were different. In an effort to learn the cause of this, 2 things were done; a string of suspension insulators was circulated to the Locke, Ohio Brass, and General Electric laboratories; and identical bushings were tested in the Westinghouse and General Electric laboratories. These moves, while of some benefit, did not lead to any lasting results. Then the laboratories of Westinghouse and General Electric, between whom the widest divergence in results existed, began to interchange information on testing procedure. Soon Ohio Brass joined the group, then Locke, and finally Allis-Chalmers. For a while the group was known as the "laboratory group" and later as the "EEI-NEMA subcommittee on correlation of laboratory data."

No effort will be made in reporting the work of this committee to include any supporting data—only the final results will be given and with a minimum of explanatory remarks.

A paper recommended for publication by the AIEE committees on power transmission and distribution, electrical machinery, and protective devices. Manuscript submitted February 26, 1937; released for publication April 20, 1937.

## Test Conditions and Method of Analysis

FLASHOVER TESTS

Before any effort was made to agree upon flashover values for common use, the committee laid down the requirement that the test points from which the curves were obtained in any of the participating laboratories should be within plus or minus 5 per cent of the average curve of that particular laboratory. The requirement was also made that the curves of all the laboratories be within a spread of less than 5 per cent. These requirements covered both impulse and 60-cycle flashover tests.

On this basis it is reasonable to expect that the individual points in any laboratory may have an extreme variation from the average curve of plus or minus 8 per cent. Consequently, when the curves based upon the average results of all the laboratories are used for determining flashover values the tolerance of points detained in any specific laboratory from the general average curves should be plus or minus 8 per cent.

During the course of the work of the subcommittee, each laboratory developed its own type of equipment and methods for producing and measuring impulse voltages. The study of the technique of impulse testing was taken up a few years ago by a subcommittee of the AIEE instruments and measurements committee and the technique has since then become more and more standardized. The laboratory group had for its major problem the study of the factors which cause divergence in results among the various laboratories rather than a study of the details which would lead to extreme accuracy. This latter topic is more properly the work of the AIEE instruments and measurements committee.

Flashover values were obtained on both the 1x5- and 1.5x40-microsecond waves. These 2 waves are among those proposed as standard by the AIEE subcommittee on lightning and insulators. For the work on this subcommittee the first number in the wave designation was taken as indicating the time in microseconds from the virtual time zero to actual crest voltage, and the second number as indicating the time from the virtual time zero to the point on the tail of the wave where the voltage is half of the crest value. The flashover data recorded is the crest value of the minimum impulse flashover voltage (full wave) and is given for both negative and positive polarity waves.

The virtual time zero is the point of intersection with the zero voltage deflection line of a line drawn through

| 14 | 1,565 | | 1,265 | 1,275 |
| 15 | 1,670 | | 1,345 | 1,360 |
| 16 | 1,775 | | 1,425 | 1,445 |
| 17 | 1,880 | | 1,505 | 1,530 |
| 18 | 1,985 | | 1,585 | 1,615 |
| 19 | 2,090 | | 1,665 | 1,700 |
| 20 | 2,200 | | 1,745 | 1,785 |

**Tolerances**

These values represent average results of tests on suspension line insulators of different design and manufacture made in different laboratories. When tests are made in any particular laboratory upon an insulator unit or assembly of specific design and manufacture, the flashover should be within plus or minus 8 per cent of the value given in the tabulation.

In accordance with AIEE Standards No. 41, the comparison should be made on the basis of the average flashover obtained from tests on 3 separate insulator units or assemblies.

NOTE: Negative wave flashovers are inherently more erratic than positive wave flashovers resulting in a greater chance of the tolerances being exceeded occasionally.

* Dual values are due to unstable conditions the cause not being known.

**Tolerances**

These values represent average results of tests made in different laboratories. When tests are made in any particular laboratory using the rod gap as a basis of comparison the flashover voltage shall be taken from the above tabulation and shall be considered as correct within plus or minus 8 per cent.

NOTE: Negative wave flashovers are inherently more erratic than positive wave flashovers resulting in a greater chance of the tolerances being exceeded occasionally.

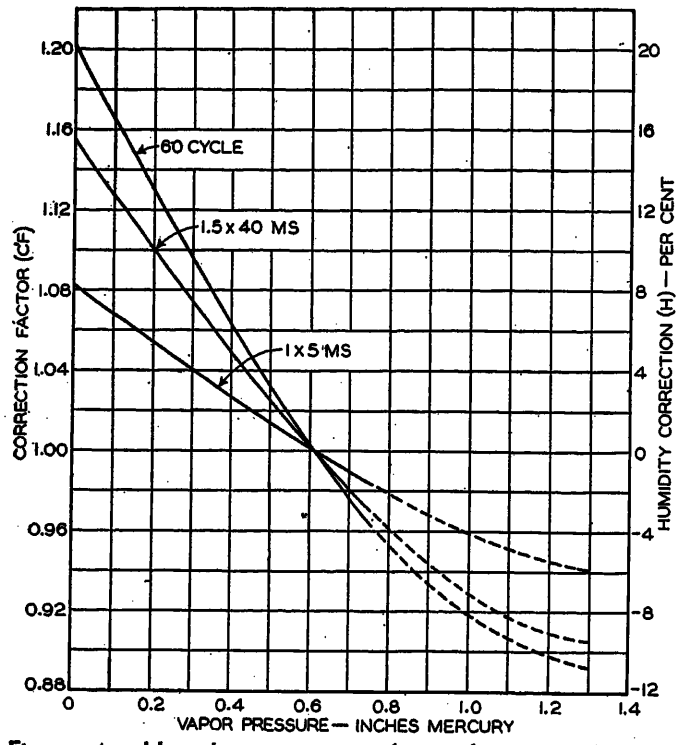

**Figure 1. Humidity correction factor for 60-cycle and positive-wave impulse flashover of rod gap and suspension line insulators**

For humidities 0.75 inch and above the correction is less reliable on account of the erratic data from which the correction was determined

Curve values apply to flashover voltages above 141-kv crest. For lower flashover voltages reduce H in proportion H′ = H kv/140

points on the front of the wave at 10 per cent and 90 per cent of the crest voltage deflection.

All 60-cycle tests were made in accordance with the rules of the AIEE.

Voltage measurements were made in some cases by means of sphere gaps and in other cases by means of the cathode-ray oscillograph. The flashover values given are all based on the revised sphere gap calibrations given in the report of the AIEE subcommittee of the instruments and measurements committee, and published on page 783 of the July 1936 issue of ELECTRICAL ENGINEERING.

## Humidity Effects

Data on the effect of variations of humidity on the flashover have been analyzed and correction factors developed. The flashover data for each insulator assembly and gap spacing were plotted against the recorded humidity and the flashover voltage determined for the standard vapor pressure. This reference value was then used as the base for determining individual correction factors for the test points. The curves of correction factors thus obtained for various insulator assemblies and gap spacings were combined and the most probable average curve determined. The accuracy of the data did not support any differentiation between the correction factor for rod gaps and insulators at the present time.

It should be noted that there is a wide variation of the points in some cases, especially for the higher values of humidity. Accordingly, it is highly possible that some inconsistencies may be encountered when flashover tests are made at high humidities.

## Results

### FLASHOVER DATA

The average flashover voltages agreed upon for insulators and rod gaps are given in tables I, II, and III. In the opinion of the committee these values are sufficiently accurate to warrant their use for co-ordination purpose and are recommended for use until such time as sufficient additional data are obtained to confirm or modify them.

### HUMIDITY CORRECTION

The curves showing the correction factors to be used for variation in humidity are shown in figure 1. The correction is given in 2 forms: As a "correction factor" by which the observed flashover is to be multiplied; and as a "humidity correction" which is the percentage to be added to or subtracted from the observed flashover.

**Table III. 60-Cycle Voltage Flashover—Suspension Insulators, 10-Inch Diameter, $5^3/_4$-Inch Spacing, and Rod Gaps**

SUSPENSION INSULATORS

These values represent average results of tests on suspension line insulators of different design and manufacture made in different laboratories. When tests are made in any particular laboratory upon an insulator unit or assembly of specific design or manufacture, the flashover should be within plus or minus 8 per cent of the value given in the tabulation. In accordance with AIEE Standards No. 41, the comparison should be made on the basis of the average flashover obtained from tests on 3 separate insulator units or assemblies.

ROD GAPS

These values represent the result of tests on rod gaps made in different laboratories. When tests are made in any particular laboratory using the rod gap as a basis of comparison, the flashover voltage shall be taken from the above tabulation and shall be considered as correct within plus or minus 8 per cent.

It should be noted that the sphere gap is the standard for voltage measurements and that the rod gap is to be used only when approximate results will be satisfactory.

# Insulation Co-ordination

By PHILIP SPORN
FELLOW AIEE

I. W. GROSS
ASSOCIATE AIEE

## I. Introduction

THIS SUBJECT of insulation co-ordination has been an active one for the past 10 years or so. It was initially presented and discussed in 1928.[1] Since then, the subject was taken up by practically all groups interested in the transmission problem including designers and operators of electric systems. As the study of the problem gathered headway, the need for further investigation work became quickly apparent. A great number of individual researches were thus started. All of them although closely related were not entirely co-ordinated. Each of them, however, in its own way, arrived at a solution of all, or of a part of the problem of co-ordinating the insulation strength of the electric system.

Such investigation and research work included[2–15] field investigation of lightning on transmission lines, determination of system overvoltages, experience in actual practice, collection and analysis of operating records of apparatus and system performance. In the laboratory, a great deal of work was also done in determining the insulation strength of various pieces of apparatus and equipment. Included in this work was a determination of transformer safe impulse strength, flashover characteristics of insulators, gaps, and some work, still incomplete, on impulse strength of switch insulators and bushings.

## II. Objective of Insulation Co-ordination

All of this work, the scope and inter-relationship of which is daily becoming closer, has as its goal, insulation co-ordination.

Insulation co-ordination has 2 main objectives: (1) protection of service and equipment, and (2) economy. Strictly speaking, however, these 2 objectives merge into one—economy. This is true of every problem in protection. In the case of insulation co-ordination, what is aimed at is an electric system so insulated in its various parts and such an arrangement in the insulation strengths of the various parts as regards one another that under all conditions the grade of service aimed at is obtained at a minimum cost. In the item of cost, there must be included, of necessity, fixed charges on first cost of equipment, cost of damages, cost of outages, cost of spare equipment, and cost or value of decrement or increment in good will.

## III. More Detailed Statement of the Co-ordination Problem

As stated above, insulation co-ordination from a very broad standpoint becomes an economic problem. That, however, is not adequate for a thorough analysis of the problem. For in any such analysis it must be recognized that what one is generally confronted with in a physical plane is insulation strength or insulation failure, both in the right and in the wrong places.

Now insulation strength raises the question of overvoltages. These overvoltages may be divided into 3 groups:

First: Those due to 60-cycle or normal frequency
Second: Those due to switching surges
Third: Those due to lightning

In the past, 60-cycle overvoltages have, in general, not been the subject of any grave concern and we can view the standard overvoltage test of equipment as a safe criterion to use in selecting insulation on a normal frequency basis alone. However, the fact that apparatus designed, tested, and used on the standard double-voltage test has given satisfactory service should not blind us to the possibility that a less severe 60-cycle test would have given equally satisfactory results. If this should prove to be true, it is obvious that insulation can be reduced from the past standards even on a 60-cycle basis with considerable economic gain and without any loss of reliability of service.

The second type of voltage to be protected against is the switching surge. Here, our basic knowledge on switching surges, both as regards the characteristics of such surges and the ability of insulation to withstand them,[15,16] needs enlargement. However, troubles from this source have not been frequent. But switching surges can by no means be overlooked in setting up insulation levels and carrying through any plan of co-ordination.

The third type of overvoltage is the one which has been given most consideration during the past decade, namely, lightning voltages, and it is around this phase that insulation co-ordination problem now largely centers.

The insulation used to furnish protection against these overvoltages must of necessity be of the same material as that used to supply the insulation against the *normal* 60-cycle voltages, that is, it must consist of additional oil, fiber, air, or porcelain. The only problem is how far to go if that method of avoiding trouble is chosen. The general principle of overinsulation, that is, adding insulation above past accepted standards has not proved very successful. Where it has been resorted to in the past and has not resulted in the mere transferring of the

A paper recommended for publication by the AIEE committees on protective devices and electrical machinery. Manuscript submitted March 26, 1937; released for publication April 12, 1937.

PHILIP SPORN is vice-president and chief engineer of the American Gas and Electric Company, New York, N. Y. I. W. GROSS is electrical research engineer with the same company.

1. For all numbered references see list at end of paper.

trouble to some other point in the system, it has invariably been at heavy economic expense. The alternative to additional insulation is a group of protective devices such as gaps, lightning arresters, etc. It is unfortunate that, although a great deal of practice has concentrated in that line, altogether too little has been known about most such devices as lightning arresters and gaps. Some of the more recent work on insulation co-ordination has clearly brought this out.

In any event, regardless of whether adequate insulation alone or overinsulation alone is used, or protective devices alone, or a combination of these is employed, it is apparent, as was initially[1] clearly shown that insulation levels must be set up for all the different groups of apparatus, with proper grading between all the links in every insulation chain at any particular level, and satisfactory margin of safety supplied at each of the levels.

## IV. Information Needed

In setting up such insulation levels, there are several essential requirements: First, the expected magnitude and characteristics of overvoltages must be known with some degree of certainty; this applies not only to lightning voltages but also to 60-cycle and switching surge voltages. Coupled with this, information on the safe insulation strength of apparatus must be available. Finally, the voltage protective characteristics of the protective devices used under operating conditions must be known with a reasonable degree of certainty.

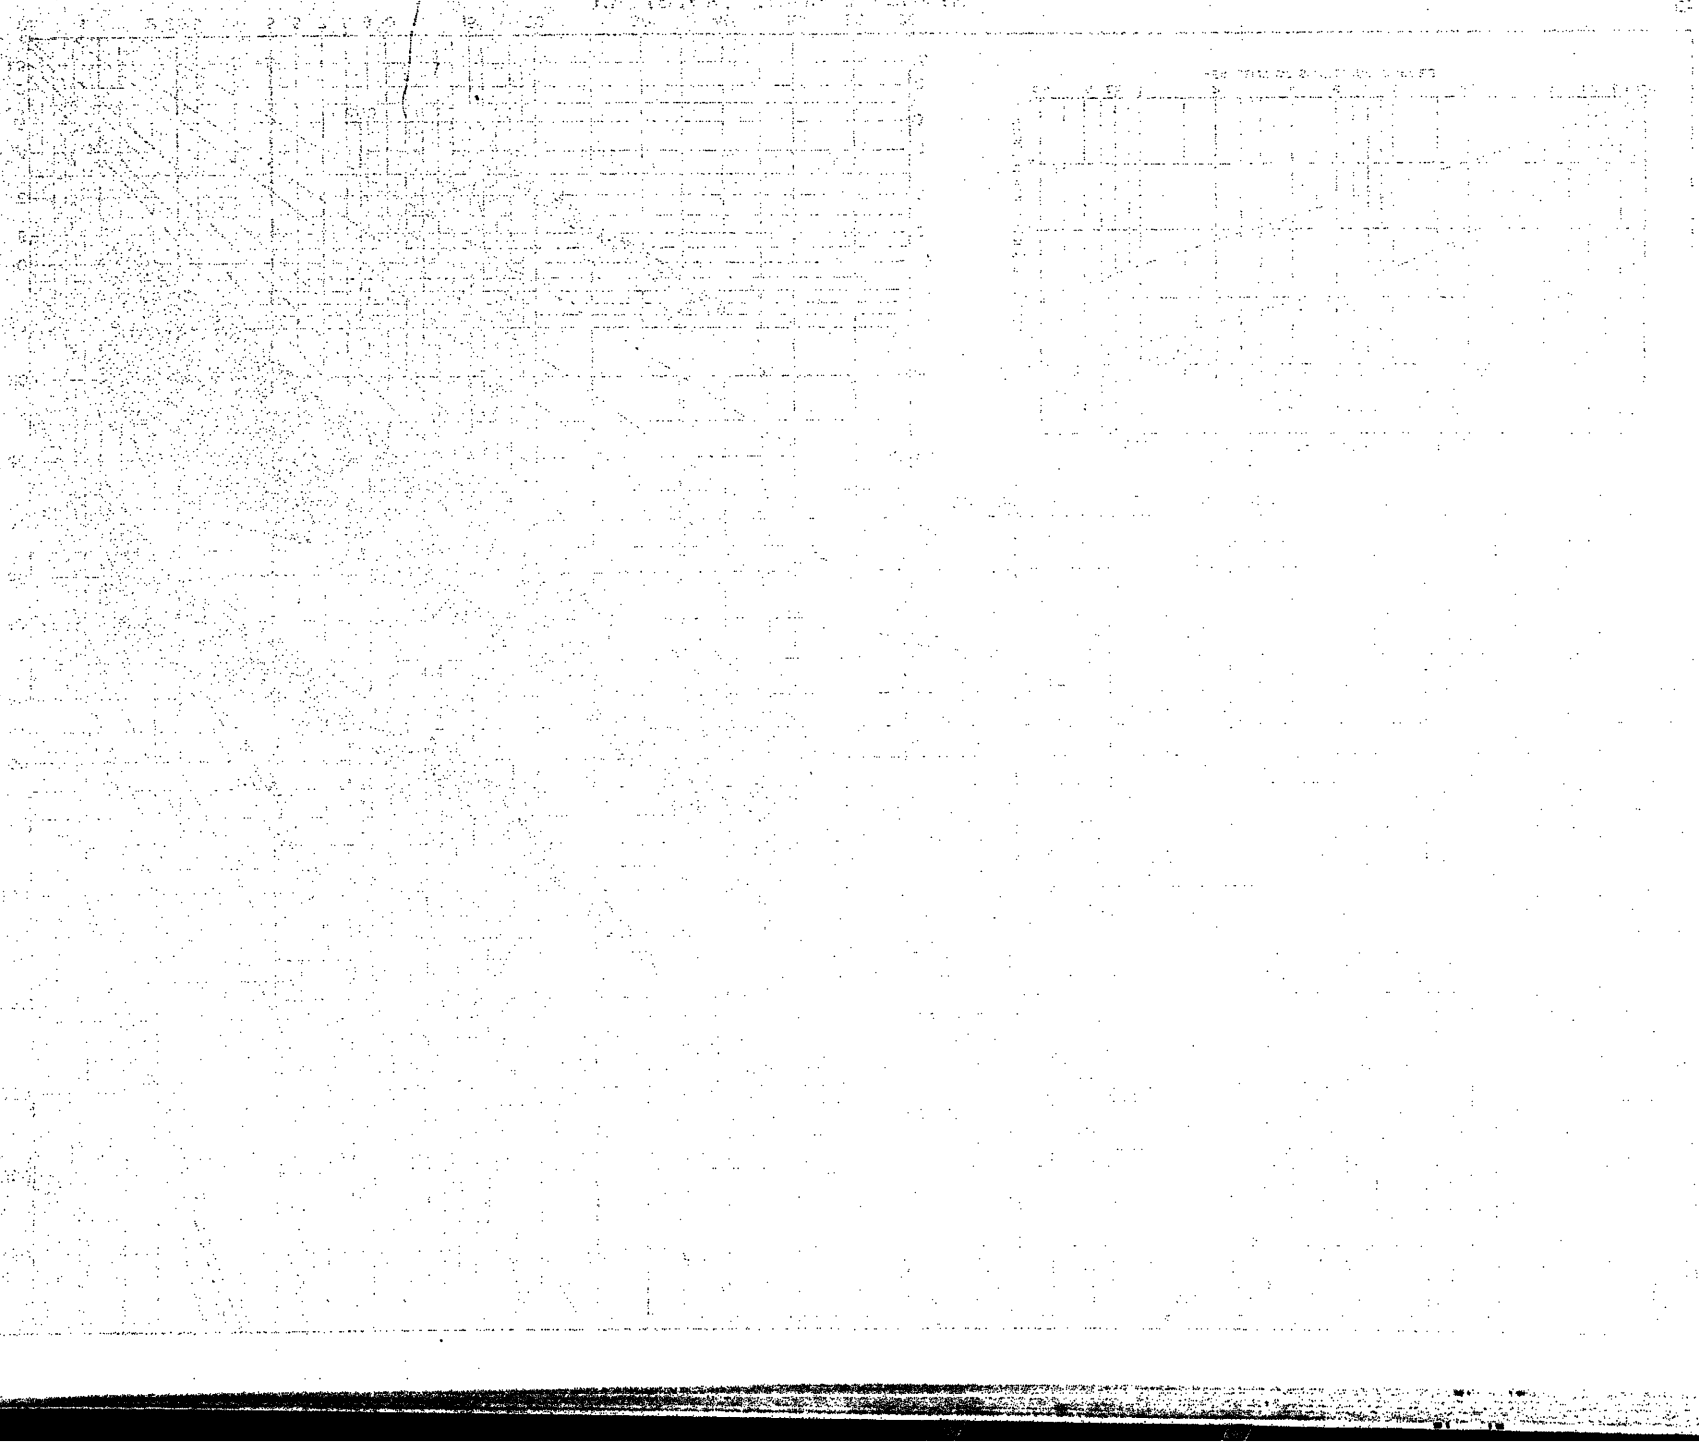
In this connection an important factor which has received very little attention is the question of margins at the various insulation levels which are finally adopted between equipment and protective device. For example, if a transformer will withstand, safely, an impulse voltage of, say, 600 kv, the question must be asked as to how much margin should be allowed between the transformer and the protective device to insure that the protective device will prevent excessive voltage on the transformer. The same consideration must obviously be given to other pieces of equipment on a system, such as bushings, bus insulators, instrument transformers, etc. The correctness of such margins as adopted will eventually have to be tried out and proved under operating conditions.

As information of this kind is obtained and correlated, it will eventually make possible a scientifically sound coordinated system of insulation levels for the various operating voltages with proper margins or steps for every insulation level between the different component parts of the transmission system, such, for example, as between the transformer and the switch insulators, between the switch insulators and the bus, and between other similar links in the insulation chain.

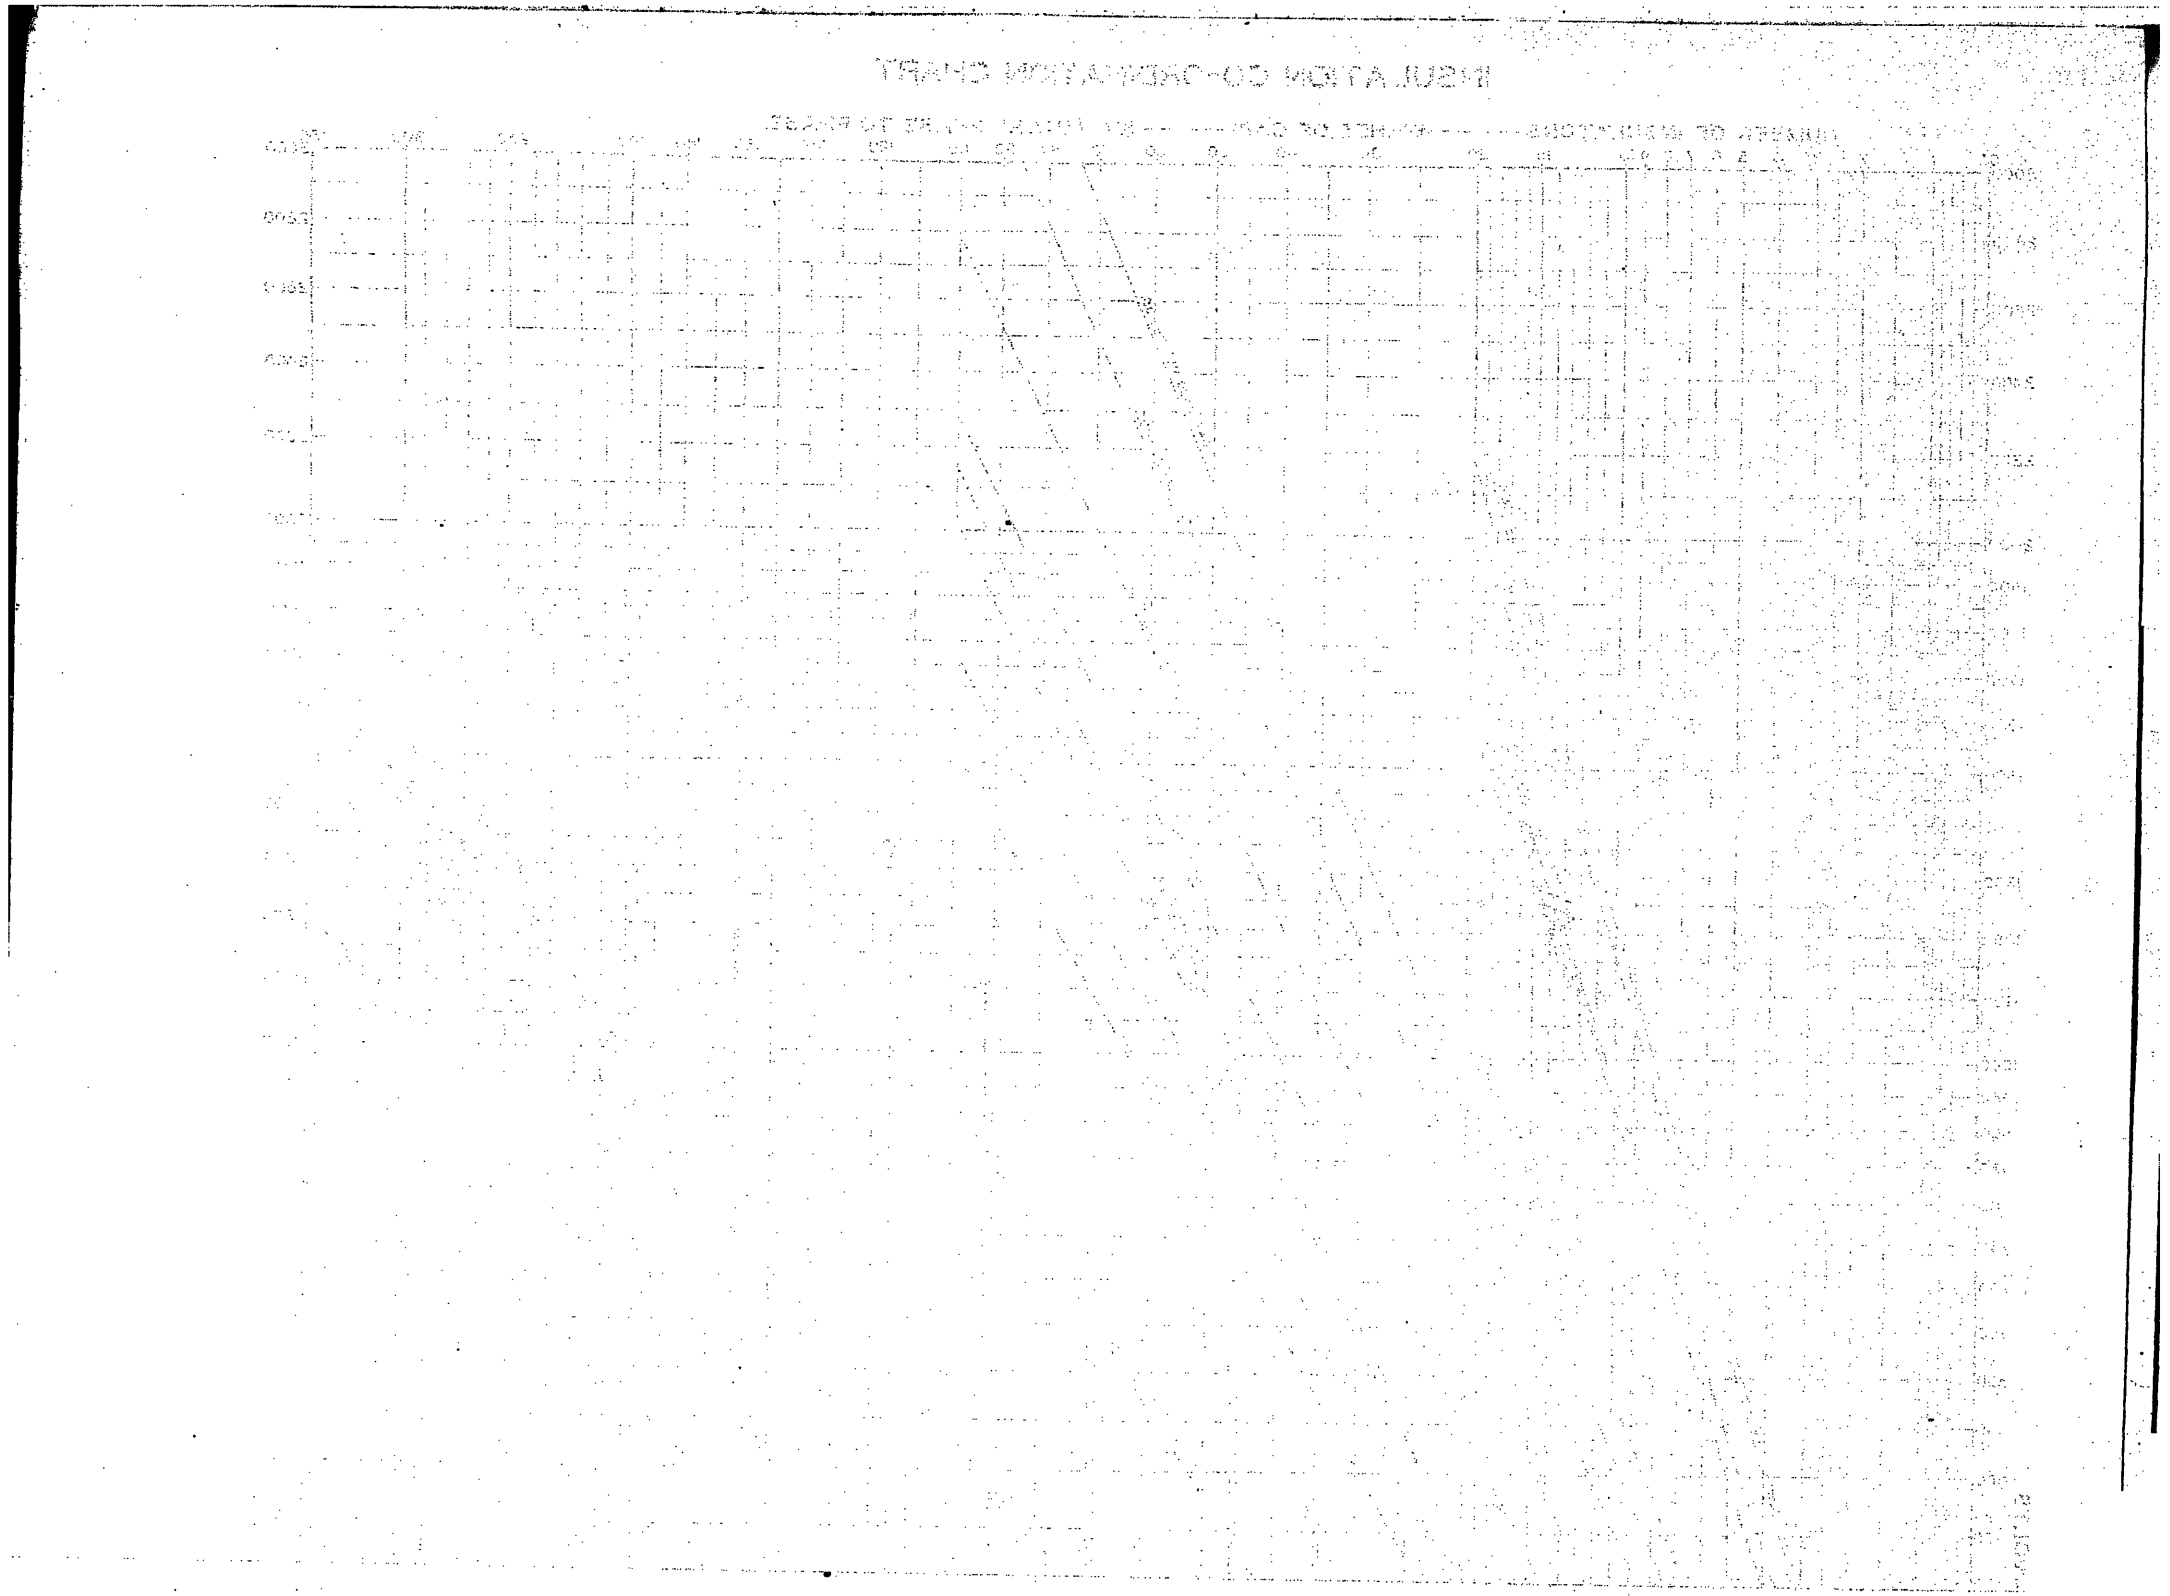
## V. Progress to Date

In reviewing some of the work which has been done to date, the following points are of interest as indicative of the progress made in insulation co-ordination: First, 60-cycle strengths are pretty well known for transformers, bushings, suspension insulators, pedestal insulators, gaps, etc. Second, some work has been done in obtaining magnitude of switching surges and data on the ability of insulation to withstand them. Third, and this is probably the most important, impulse strength of many of the most important items of high-voltage equipment has been determined with some degree of certainty. Thus transformers are now being commercially impulse-tested; information is available on impulse strength of transformer bushings; the characteristics of the lightning arrester which, in the past, was a semi-mysterious protecting device, are much better understood and the protective ability of the arrester fairly well known under an ever-increasing number of operating conditions. Also, a great deal of work has been done in determining the impulse characteristics of gaps under surge conditions. In this connection, it is pertinent to point out that the recognized impulse laboratories today have so improved and perfected their technique that they are now almost universally operating on a basis where comparable data can be obtained.

While much data have been obtained, and are being obtained, on impulse characteristics of insulation, the main problem of utilizing these data effectively in insulation co-ordination has not progressed as rapidly. This however, is natural in view of the fact that a practical and workable system of co-ordination must await the time when information is available on the insulation strengths of all the apparatus concerned and accurate knowledge of the impulse characteristics of the protective devices employed. Fortunately, however, a great deal of the fundamental data are now available and insulation co-ordination is beginning to take form. Only recently, as reported in the companion paper, basic insulation levels for the preferred voltage ratings have been adopted. This will undoubtedly serve as a stimulus to the more active pursuit of the work needed to bring about co-ordination. But it must not be forgotten that the entire problem of correlating the laboratory test data, the field data, and various ideas and theories of electrical system design into a practical, workable system of insulation and protective levels still remains to be done.



### Insulation Co-ordination Chart



So many different groups have been working on this subject each within its own field that it is believed that it will be helpful to present a rather complete picture of the insulation strength of major equipment and protection available. With this thought in mind, the authors have collected and correlated a great deal of the available data on the subject and have prepared it in graph form. This is shown in the insulation co-ordination chart, figure 1. It is presented as an accumulation of data bearing on the insulation problem which in their own work the authors have found useful time and again to get and keep an over-all picture of the insulation problem in all voltage classes from 1 kv to one step beyond the present range of operating voltages, namely, 347 kv.

On this chart there have been plotted, in the upper left-

# INSULATION CO-ORDINATION CHART

NUMBER OF INSULATORS--------INCHES OF GAP-------- KV. (R.M.S.) PHASE TO PHASE.

hand corner, the impulse characteristics, both positive and negative, and 60-cycle flashover values of suspension insulators from 1 to 20. Flashover characteristics of the rod gap, which has been extensively used during the past number of years as a measuring and test device for co-ordinating the work of the laboratories, are shown immediately below the insulator data. In the lower right-hand corner is a graphic presentation of the magnitude of switching surges as actually observed from field studies under operating conditions. The major group of lines running diagonally through the center of the chart represents the insulation characteristics of various pieces of equipment, and lightning arresters and also multiples of system line to neutral voltages. For easy identification, the preferred voltage class of insulation is shown by vertical lines located at the proper spacing as determined by the phase-to-phase system voltage scale at the bottom of the chart.

By the use of the chart it is possible to get a rather complete over-all picture of the insulation situation in any voltage class by merely following a vertical line marked with the preferred voltage class: For example, reading values from the chart, on a 138-kv system the impulse test on transformers would be 680 kv, the impulse flashover of the bushing 720 kv. A 100 per cent arrester would have an *IR* drop, at 5,000 amperes through the arrester of approximately 600 kv, leaving a margin between the arrester and the transformer of approximately 90 kv. To determine the test gap which would be used in testing the 138-kv transformer according to AIEE transformer standards, merely trace horizontally from the intersection of the 138-kv vertical line with the transformer test (diagonal line) to the gap curve which shows a $42^1/_2$-inch gap. Such a gap, however (tracing vertically upward) would have a flashover of approximately 770 kv with a negative $1^1/_2$x40 wave, 925 kv with a 1x5 negative wave, 1,290 kv if the impulse rose at the rate of 500 kv per microsecond positive, and 1,600 kv if the impulse rose at the rate of 1,000 kv per microsecond. It is obvious that such a gap furnishes little protection to the transformer under impulse if it is assumed that the test value of the transformer is approximately its safe strength.

Another interesting point can be determined from this chart. Again start at the intersection of the 138-kv preferred voltage class line with the transformer test curve and go horizontally to the gap curve for 1,000 kv per microsecond. It is observed that a gap set at $16^1/_2$ inches would flash over at 690 kv, that is, at the same value at which the transformer would be tested. Following down to the 60-cycle gap flashover curve, it is seen that such a $16^1/_2$-inch gap would flash over at 165 kv and again going horizontally from this point to the 138-kv preferred voltage class line it appears that such a voltage would be approximately 2.1 times normal line to neutral voltage. Thus a gap which will limit a steep wave front positive surge in order of 1,000 kv per microsecond to the tested transformer strength would have such a low 60-cycle flashover that it would undoubtedly result in increased service outages under overswitching surge conditions.*

In applying lightning arresters for protection there should, of course, be some margin between the terminal voltage of the arrester under impulse conditions and the safe strength of the apparatus which it is to protect. This margin has been shown near the bottom of the chart for the 100 per cent arrester, as a full line curve. It will be noted that this margin varies from approximately 35 kv in the 2,500-volt class to 120 kv at an operating voltage of 230 kv. This gives an idea of the general range of margins which have been possible in recent years. A curve slightly higher up is also drawn showing the impulse characteristics of an 80 per cent lightning arrester. The so-called 80 per cent arrester is taken as one having 80 per cent of the active material of a 100 per cent arrester and in general is considered suitable for use only on a grounded neutral system of normal rating or on an isolated neutral system rated 80 per cent of the conventional 100 per cent arrester voltage.

Reverting to the example of the 138-kv insulation cited above, it will be noted that a 100 per cent arrester would not supply any protection for a transformer in the 115-kv class. However, if an 80 per cent arrester were used there is a margin between the arrester and 115-kv class of transformer insulation of approximately 110 kv. This 80 per cent arrester, however, has little margin for a standard 92-kv transformer, the transformer test and lightning arrester *IR* drop being about equal. Thus, it is apparent that if it is deemed safe to use an 80 per cent arrester on a 132-kv system (and this is entirely feasible where the 60-cycle voltage is limited by system grounding, etc.) it is possible, from the impulse protection point of view, to use insulation in the 115-kv class. If it is possible to cut the arrester to below 80 per cent it may be possible to use a transformer even in the 92-kv class without decreasing the margin of safety appreciably below that used in the past with standard 100 per cent arresters. Cases of this kind where reduced insulation has been used on our own system with a substantial economic saving will be cited below. In every case careful analysis shows that ample margins of insulation remained between the transformer and arrester levels.

It is believed that this chart will be found useful in analyzing in a general way with considerable accuracy many problems of the above character.

It should be pointed out that some of the data in the above chart are subject to further check and confirmation, such, for example, as impulse flashover of switch insulators and the *IR* drop characteristics of modern lightning arresters under present-day conditions. All data, however, have been collected from sources believed to be reliable and are the best available at the present time.

## VI. Present Insulation Practice of American Gas and Electric Company

In the work on their own system the authors have been using the principles of co-ordination over the past 10 years. Initially the basic idea sought was to have the various

* This, however, does not take into account the possibilities of ultrahigh-speed breaker reclosure.

component parts of the transmission system properly insulated with regard to each other and all properly insulated for the operating voltage and conditions encountered. But as they progressed in their work and in thinking out the problem, the ideas of co-ordination began to offer more and more means of reducing intelligently the cost of transmission equipment. Some 5 years ago, therefore, the authors first went thoroughly into the insulation problem presented by a 132-kv transformer installation and, as a result, placed in service a reduced insulation transformer, that is, one with insulation lower than normal for the system rating. As a matter of fact, they actually used 115-kv insulation on a grounded-neutral 132-kv system. Several very similar installations involving large 132-kv transformer banks have been placed in service on their system during the past year and others are being added. A comparison of the insulation co-

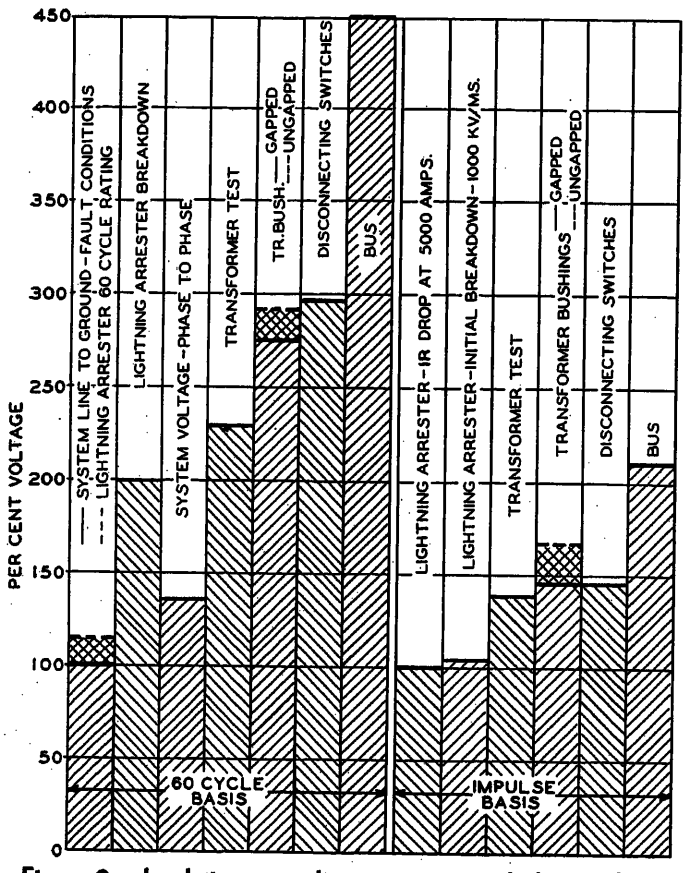


**Figure 2. Insulation co-ordination on grounded-neutral 132-kv system of American Gas & Electric Company (installation in 1936)**

ordination of such a transformer with some of the other links in the insulation chain in the station is shown in figure 2. It will be noted that on an impulse basis, the transformer tested strength is approximately 40 per cent above the lightning arrester *IR* drop. It will also be noted that the switch insulators have an impulse strength some 5 per cent above the transformer strength and the bus some 50 per cent above the switches. The transformer bushings were gapped, according to present transformer practice, at 5 per cent above the transformer test. In this connection, however, it may be well to point out that the practice of gapping transformer bushings in service to the 5 per cent margin above the transformer test recommended by the transformer subcommittee has been recently discontinued by the authors.

There are 3 reasons for doing this: First, the impulse characteristics of the transformer bushing, with gap spacings recommended, does not indicate that protection will be afforded the transformer on steep wave fronts; second, if the gap on the bushing flashes over there is almost sure to be sufficient damage to the bushing so that extensive repairs have to be made, in many cases, not only to the bushing itself but to other bushings. Two cases of this kind have been experienced in the last year on gapped bushings. Third, transformer bushings in the lower voltage class, if gapped, have such small mechanical clearance that these gapped bushings become hazards in a major substation instead of safety devices.

It will be noted also in figure 2 that the bus insulators, both impulse and 60-cycle, are placed well above any other equipment in the station. This policy the authors have consistently followed on the basis that any damage to the bus structure may involve service interruptions sometimes that will affect a larger area of service than damage to any other piece of equipment of embarrassing durations.

## Selecting Transformer Insulation

In selecting reduced insulation for large-size high-voltage transformers, the procedure followed by the authors within the past year has been as follows:

1. The overvoltages on a system, due to faults or other effects, such as hydro, are calculated and on this basis a suitable arrester is selected adequate to stand up in service under the worst 60-cycle voltage conditions.
2. The impulse characteristics of this arrester are determined.
3. The transformer impulse strength is placed at a margin considered safe above the lightning arrester voltage and the class of insulation into which that transformer falls is then selected.

In other words, the start is with the lightning arrester as a protective level; the necessary margin between the arrester and the transformer is then set, and then the transformer insulation level is picked. As mentioned above, this has resulted on the authors' system in the selection during the past year of several large-sized transformers with 115-kv class insulation for 138-kv class of service. There has even been considered in one case, so far, and it is believed feasible, to use so-called 92-kv class insulation for 138-kv service where 60-cycle voltage conditions are favorable.

This plan of so-called reduced insulation not only results in economic savings in the initial cost of the transformer, but also gives added protection to other equipment in the station by holding the impulse level low with a low-rated arrester. In view of the fact that the authors of late have gone extensively into the practice of locating lightning arresters directly on the transformer and are

gradually removing them from the lines at the line entrance, greater protection will be supplied the entire station by the reduced-rated arrester than would be possible with the so-called 100 per cent arrester. Thus, the initial reduction of transformer insulation to a lower voltage class has resulted not only in a more economical transformer but greater protection for the entire station concerned.

## Bus and Switching Insulation Practice

In tables I and II are given 60-cycle and impulse voltage characteristics of the present standards which are being used for switches and insulators in station design on the authors' system. A comparison is made in these tables with values recommended by National Electrical Manufacturers Association. It will be noted that the authors' practice calls for flashover values, both 60-cycle and impulse, except for post-type insulators in the 132-kv class, which are higher than NEMA recommendations. While it may be possible to use insulation with lower flashover than the authors' indicated practice, it should be kept in mind that bus insulators are only a small portion of the cost of the total station equipment, and the steps in insulation from one insulator to another are so large that it is not usually feasible to hew closely to a given minimum insulation value. Further, the bus is one part of the system that it is well to protect against flashover under any condition, leaving the more finely graded steps of insulation to be worked out for the other links of equipment and apparatus in the station.

It will be noted that there is one outstanding case where the authors' insulation practice is below a NEMA recommendation, and that is for post-type insulators in the 132-kv class where the impulse strength is about 15 per cent below NEMA recommendation. It should be pointed out, however, that in practically all of the cases where these are used there exists lightning arrester protection designed to hold impulse voltages down below the bus insulator level. It is interesting to note, in this connection, that this lower insulation which has been used in some 35 stations on their 132-kv system, has according to their records, some of which go back 20 years, never resulted in a major case of trouble.

## VII. Work Still to Be Done

As pointed out in the early part of the paper, a great deal of work has been done in obtaining fundamental data on the characteristics of insulated equipment and protective devices. The work of correlating these data and setting up workable insulation systems has been in progress for the past few years. Further and fairly rapid progress may be expected in the next 2 years. But it needs to be stressed that whatever co-ordination system may be set up, it is bound to be, in part at least, based on theory, and to that extent it must receive its final test in field experience.

The authors have outlined above in a rather general way, some of the practices which they have adopted as a result of their work on the problem and on which we are now getting their field trials. There have also been outlined some of the methods which they have employed in arriving at the various insulation steps which they have employed in their more recent design work, and it is hoped that some of the work described above, the basis on which it was arrived, and the data used, may be useful to others who are now working on this problem. The authors look forward with confidence to the not too distant future when a group of insulation levels will have been set up, with all links of the insulation chain specified in magnitude, and with workable margins between links properly applied.

There is one final point which needs to be stressed in connection with this work of insulation co-ordination and that relates to equipment now in service which was designed and built with very little, if any, consideration given to its impulse strength. A great deal of such equipment is now in service and will of necessity have to remain so for many years to come. The problem of co-ordinating and protecting this insulation is one which will assume considerable importance in the future, particularly when the equipment becomes older. It is believed, however, that as progress is made in the simpler problem of insulation co-ordination on new equipment, the prin-

## Fire Precautions in Electrical Stations

THE PAPER "Fire Precautions in Major Electrical Stations" by F. C. Winfield (A'22) chief electrical engineer, Merz & McClellan, Newcastle-on-Tyne, England, was presented recently in London before The Institution of Electrical Engineers. In this 10-page paper, which has 5 illustrations, the fact is observed that while electrical duplication or multiplication of equipment is recognized as essential, its complement—true physical segregation of duplicates to secure against the fire or explosion risk—has not received as much attention. However, it is emphasized that the rare occurrence of serious fires, a condition secured by the use of sound plant and good protective gear, justifies a different treatment. It is stated that "the eggs shall not be carried in one basket"; however, the conditions do not require that each "egg" be carried in a separate basket. A single clear division of plant into 2 parts is frequently sufficient. The "unit principle" of electrical arrangements, which means that each major item of equipment is provided with its own separate and distinct control and auxiliary equipment, is favored by the author.

The governing principles in fire considerations may be enumerated in 3 classes:

1. *Provisions which always ought to be made:* (*a*) the use of switchgear and plant of adequate capacity, soundly designed and constructed and provided with suitable automatic protective arrangements; (*b*) the complete electrical and fire sectioning into at least 2 duplicate parts of the switchgear, transformers, cables, etc., supplying an electric system or independent portion of a system; (*c*) minimum arrangements for fire fighting; (*d*) heating of buildings to reduce risks of insulation failures.

2. *Provisions that are easy and inexpensive to make and that reduce the spread of fire or consequential damage within a fire section:* (*a*) sealing of holes in floors or internal parts of any single fire section that has natural structural barriers; (*b*) the elimination of combustible matter not inherent to plant.

3. *Provisions that while not essential are desirable and should be applied where the importance or special conditions of the station justify the expenditure:* (*a*) floor drainage to remove oil quickly; (*b*) permanent and local fire-extinguishing plant either automatic or remote-controlled if the station is permanently attended.

An important factor in any oil-fire fighting arrangement is the dense black smoke which impedes or prohibits access to the seat of the fire. This is a most serious consideration in dealing with fires which occur in the inner regions of large power stations, for example, and for this reason it is strongly recommended that where possible, and except where small-size plant only is in question, all large transformers or switchgear should be mounted in separate buildings or in chambers opening to the outer air and sealed off from the inner side. Where this is not possible, automatic or remote-controlled forms of fire attack should always be employed, to make immediate attack on the fire without actual access being necessary.

A second important matter in all electrical failures is to eliminate the electrical contribution to the fire as rapidly as possible by tripping the switches connected to the affected bus bars and the corresponding remote feeder switches. If a sound basis can be found for doing this automatically so much to the good, but in any case operating instructions ought to provide for immediate action of this type, starting with the section switches, whenever a fire or explosion occurs.

Since prevention is better than cure, routine testing of insulation to find possible sources of failure that might cause fire is desirable. Unfortunately, no form of routine insulation testing has yet been devised which has not important objections. The so-called Doble method of testing, which makes routine field tests of watts loss and power factor with a specially portable apparatus and compares these one against another and all against continuous records of past testing, has shown promising results although there are at present certain physical limitations in its application to metalclad switch equipments.

Despite all precautions, fire cannot be absolutely precluded and the only ultimate safeguard must be a reasonable fire-sectioning of the plant, so that a fire or explosion is limited in its worst effect to a section or group of plant items which can in emergency be done without. Distinct buildings are to be preferred to barrier walls to reduce the possibility of damage by explosions, and it is suggested that one wall of structures have adequate windows or doors secured lightly so that a relief vent will be provided to reduce the force of explosions. Because of the rarity of serious fires, the actual loss sustained in damaged equipment or buildings is not of importance.

# A New High-Speed Cathode-Ray Oscillograph

By H. P. KUEHNI
ASSOCIATE AIEE

SIMON RAMO
ASSOCIATE AIEE

## Synopsis

A historical review of advances in the design of high-speed cathode-ray oscillographs and in particular a description of the development, performance, and application of a new type oscillograph is presented in this paper. The new instrument embodies a sealed-glass, high-vacuum, hot-cathode, cathode-ray tube for operation at 15,000 volts.

SINCE its birth in 1897[2] the cathode-ray oscillograph has maintained a position of unchallenged and ever-increasing importance in the realm of problems relating to high-speed electrical phenomena. It owes this distinction to its inherent capability of faithfully recording electrical transients of extremely short duration. Among many other accomplishments the cathode-ray oscillograph has contributed enormously to the progress in the perfection of electrical insulation and to a better understanding of insulation problems in general. For example, the knowledge of the characteristics of electrical stresses produced by lightning disturbances on power transmission and distribution systems has been greatly expanded. As a result of these studies, standardized high-voltage impulse tests are now widely made in the industry's laboratories on electrical equipment and apparatus using artificial lightning of prescribed wave shapes. The modern exact impulse-testing technique of today is quite unthinkable without the cathode-ray oscillograph. Likewise the cathode-ray oscillograph has been indispensable in the studies of recovery voltages during circuit interruption and thus in a large measure responsible for the present state of perfection of the modern circuit breaker.

The evolution of the cathode-ray oscillograph, from its early beginning to the various practical forms which are in use today, has occupied a period of 40 years. It would be impossible here to give a full and detailed account of all the valuable developmental work that has been done. However, a brief survey of the principal steps in the development is made below to serve as a background for the new cathode-ray oscillograph which is described in this paper.

## Historical Review

The earliest cathode-ray oscillograph tube which Braun[2] invented in 1897 consisted of a sealed evacuated glass tube, a "cold" cathode, an anode, a diaphragm with a small hole at its center and a fluorescent screen. The electrons, originating at the cathode, traversed the aperture in the diaphragm and impinged on the fluorescent screen to produce there a luminous spot. Shortly after, a magnetic concentration coil[3] was added by means of which the luminous spot could be focused. At first the electrons forming the cathode-ray beams were deflected magnetically; later, electrostatic deflection plates were added. With early tubes of this kind, at excitation voltages of 30 kv, Zenneck photographed fluorescent screen traces of electrical events of one millisecond duration.[7] During the course of the years the original Braun tube was gradually improved[13] by adding a hot cathode, gas, or electrostatic focusing means, and beam intensity grid controls. Today this type of tube is widely available commercially and is commonly used in low-voltage cathode-ray oscillographs of the repeating-time-axis type for the study of recurring phenomena. In slightly modified form it now also is finding an important place in the field of television.

Because of its recording speed limitations the early Braun tube was found inadequate to satisfy a growing demand for higher and higher recording speeds. This led to a radically new avenue of attack and Dufour in 1914 introduced the photographic plate inside the vacuum to let the electrons impinge directly on the photographic emulsion.[8] He used vacuum pumps to obtain and hold the necessary operating vacuum after insertion of the photographic film. At cathode excitation voltages of 50 or 60 kv Dufour obtained a recording speed of 1,000 kilometers per second. The early Braun tube had a recording speed of perhaps one kilometer per second. Based on his earlier experiments Dufour constructed the first practical cathode-ray oscillograph of the so-called internal-photography type, a description of which he published in 1920.[10] For an excellent history of the cathode-ray oscillograph with a complete bibliography up to 1925 reference is made here to a paper by MacGregor-Morris and Mines.[13]

The successful production of a practical high-speed cathode-ray oscillograph by Dufour[10] stimulated many others to follow his lead. Numerous investigators, among them Dufour himself, Rogowski[19] and Flegler, Gabor,[20] Norrinder,[22] Wood,[12] and Knoll,[29] developed new artifices such as improved methods of focusing by the addition of a second concentrating coil, division of the vacuum chamber into 2 sections having different degrees of vacuum, new shapes of cathodes and anodes, beam traps and improvements in the vacuum system. Modified forms of the Dufour-type high-voltage internal recording instruments for practical use in laboratory and field work

A paper recommended for publication by the AIEE committee on instruments and measurements. Manuscript submitted March 26, 1937; released for publication April 24, 1937.

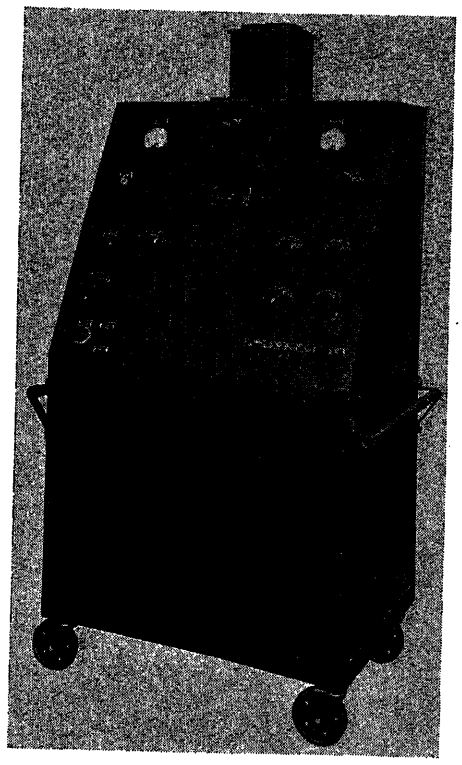

**Figure 1. General Electric cathode-ray oscillograph, type HC-15, front view**

were built in this country by the General Electric Company,[26] by Professor R. H. George,[26] and the Westinghouse Electric & Manufacturing Company.[38] Professor George used a hot cathode and electrostatic beam focusing. As a culmination in the quest for high recording speeds, Rogowski[32] in 1930 succeeded in obtaining the enormous speed of about 60,000 kilometers per second, which is $^1/_5$ the speed of light. Because of the finite velocity of the electrons this writing speed is considered to be the practical limit for the cathode-ray oscillograph. The literature from 1930 to date includes descriptions of several practical high-voltage, internal recording type instruments, some equipped with high-speed rotating film drums especially adapted to switchgear testing work (see bibliography). As a result of highly interesting development work Rogowski and his associates recently have obtained surprisingly high writing speeds with a cold-cathode type instrument at voltages as low as a few thousand volts.[64] This result was due to extremely high beam currents made possible by the use of very narrow discharge tubes having relatively high gas pressures.

During the last few years an increasing number of investigators have been studying the possibilities of obtaining high-speed oscillographic records with the film outside of the vacuum. This came about quite naturally with the growth of the commercial impulse-testing practice and the increased applications of the cathode-ray oscillograph to engineering problems. One of the principal difficulties encountered with inside recording results from the necessity for breaking the vacuum to renew a film. Despite great refinements in vacuum technique[59] the time for obtaining the proper operating vacuum after renewal of a film is not always reliably predictable. Numerous factors contribute to this behaviour. Probably the more prominent ones are unavoidable air leaks which are difficult to locate, the removal of moisture and other impurities from the oscillograph vacuum chamber, and the maintenance of the correct vacuum for best oscillograph performance at a given writing speed.

The earliest method used to obtain oscillograph records outside of the vacuum was to photograph with a camera the luminous trace on the oscillograph fluorescent tube screen. However, because of the recording speed limitations existing at that time, this method was abandoned. The solution for high-speed external recording was sought first with the aid of the Lenard[1] window. This is a very thin vacuum-tight membrane supported internally by a reinforcing grid against the external atmospheric air pressure. By using extremely high tube excitation volt-

8. Sweep-initiating unit

ages it was shown by Coolidge[18] that large amounts of electrons can be made to traverse a window of the Lenard type. Knoll[34] first built a practical cathode-ray oscillograph equipped with Lenard windows and obtained recording speeds of 5,000 kilometers per second with a photographic film held against the window (contact exposure) and a cathode excitation voltage of 75 kv. Miller and Robinson[61] have provided a Lenard window attachment for their conventional type of internal photography instrument.

Another line of attack in obtaining oscillographic records by contact exposure has been the use of a glass window coated with fluorescent material on the inside.[14] In this case the light radiation from the fluorescent screen is used to blacken the film. Investigations have been made along this line by a number of workers, Freisewinkel[68] and others, and high recording speeds were obtained in some cases. However, it also was found that unless a very thin glass window is used, the light dispersion will result in a blurred record.[73] Of course, it was known that sharply focused records can be obtained with a camera—which method places no restrictions on the thickness of the glass window—but here only a very much smaller part of the available light is used.

With the availability of commercial high-speed photographic lenses and with the attainment of sharply focused beams and exceedingly high fluorescent spot intensities one of the most interesting trends of recent years is the return to the simple external camera method of recording as used in connection with Braun's tubes. Following earlier experiments by Rogowski[41] and his associates, Dodds[56] in 1933 reported the recording by external camera of speeds of 30,000 kilometers per second at 90 kv cathode excitation with a cold-cathode tube. A year later Gondet and Beaudouin[66] described a new Dufour hot-cathode vacuum-pump type oscillograph with external-camera photography.

It having been demonstrated that very high recording speeds can be obtained by photographing the fluorescent screen from the outside, consideration was given again to a complete sealing off of the tube and the resulting elimination of vacuum pumps. Rogowski and Szeghö[62] developed a permanently sealed glass oscillograph tube with cold cathode and zinc sulfide fluorescent tube screen for 40 or 50 kv excitation voltage. The tube was hydrogen filled for protection of the cathode and to obtain a high spot intensity. Provision is made to diffuse hydrogen into the tube to replenish the loss of hydrogen through clean-up action. As cold cathodes are subject to crater formation, a loosely mounted spherical cathode was used which can be turned to expose a fresh surface by lightly tapping the tube. A complete oscillograph embodying a tube of this type was described by Parker-Smith, Szeghö, and Bradshaw[78] in 1935.

In the above brief historical review it was obviously impossible to mention all of the numerous and valuable contributions that were made toward the gradual perfection of the high-speed cathode-ray oscillograph. However, an extensive bibliography covering the cathode-ray oscillograph development, with particular emphasis on the high-speed type for transient recording, is given at the end of this paper.

## The New Cathode-Ray Oscillograph

It has been shown that the cathode-ray oscillograph is capable of enormous recording speeds. However, when we examine the recording-speed requirements from a practical engineering point of view we find that in most of the fields of application of the oscillograph ultrahigh speeds are not required. This applies particularly to impulse-testing work, to the study of lightning and lightning protection, and to investigation of switchgear problems. Because of the large dimensions of the circuits involved
